its appearance is certainly most desirable, more so in fact than in the former. The seed if sown, say, during January, February or March, has not the same favourable conditions in its favour as regards germination; other things then press for immediate attention as well. If the same seed be left until the following June, or later, it is then a year too old, hence the greater desirability of purchasing as soon as possible after it is ripe. This item of culture should be noted more particularly by private growers, who often fail to grow this handsome flowering plant so well as the market men. H. G.

## THE WEEK'S WORK.

### FRUIT HOUSES.

**PINES.**—Fruits ripening fast or required for a special date may be retarded, without loss of flavour, by removing the plants to a cooler and more airy house, keeping them drier at the roots and allowing a free circulation of warmth in the pipes. The fruit will not shrivel and will be much better treated thus than when cut and hung up. If it is desirable to keep them for a considerable time it is well to remove them when fully ripe to a cool fruit room or a vinery, giving full air front and back and placing the plants under the shade of the Vines. Houses as they become vacant should if possible at this season have any necessary repairs made good, as it is an easy matter to place the old stools in makeshift places whilst the work is in progress. It is well to limewash the walls and wash all paint and glass. The beds, when allowed to remain a long time, are often much infested with woodlice, and at this season of the year it is well to clear out old spent material and refill with new, and before putting in the new to give all walls a thorough scrubbing with hot water. Mealy bug is a terrible pest, and it often would be best to sacrifice the plants. Late fruiterers started a few weeks ago should now be growing freely, and if given a liberal temperature will take food in the way of weak guano water or liquid manure. The temperature should not fall below 70° at night, and should run up to 95° at midday or closing time, well syringing all parts of the house, beds and bare places. In dull weather raise the temperature early in the day, allowing it to decline by nightfall. Plants which promise well may be top-dressed if the pots are small, using bone-meal freely. It is necessary with plants treated thus to see that the old ball of soil does not get too dry after the new soil is added.

**GENERAL STOCK.**—With shortening days the succession Pines will need less heat, but it must be a gradual reduction, and any likely fruiterers of the Cayenne or Rothschild section should not be kept with what are termed next year's fruiterers. Very little shade will now be required, and to get the full benefit of sun heat so necessary for the plants the glass should be cleansed and all traces of permanent shading removed. Any plants potted late should be given a light dewing overhead in bright weather and be kept a little warmer than well-rooted plants. From this date less water will be needed at the roots, and though it is important to keep the plants as vigorous as possible, they should not be drawn or hard forced, and in fine weather the syringe may be plied freely between the plants, damping the walls and floors, as with a genial temperature the moisture will quickly dry up. The bottom-heat should be regular, and be kept as near 85° as possible, the minimum being 5° lower. The atmospheric temperature may range from 70° to 80° according to the weather, 10° lower being a safe night temperature, closing early in the afternoon. When watering is necessary, it should be done early in the day and thoroughly.

**SMALL PINES AND SUCKERS.**—The earliest strong suckers of the Queen section taken from early fruiterers will now be well rooted, and may be removed to the general stock or succession house,

and thus get more liberal treatment. By removing these, room will be found for later batches, and as at this date there will be strong suckers of the late fruiters, no time should be lost in potting up into 7-inch or 8-inch pots, using a size smaller for later or smaller plants. Give these the compost advised in previous calendars, pot firmly, and plunge in a bottom-heat of 90°, keeping close and giving just enough water to keep the soil moist. One good watering at the start will usually do for some time, and as they root freely give more moisture and air freely in bright weather to keep the plants sturdy. When plunging in the beds care must be taken not to loosen the plants at the collar and to see that the heat does not rise too rapidly. Shading for a short time daily may be necessary till roots are made, and at closing, which should be early, a genial temperature may be obtained by damping dry parts of the house and covering the glass at night to prevent hard firing.

**BANANAS.**—Plants with fruits well advanced cannot be fed too much as long as the plants continue to grow freely and the fruits to swell. A good top-dressing of guano or fish manure will greatly assist the fruits, and when watering give liquid manure. Bananas, being gross feeders, will take stronger food than other fruits, and at almost every watering when the fingers are well formed. Plants just showing fruit will need more than usual care at this season, as if there is too much moisture overhead the fruits decay instead of swell. A drier atmosphere is necessary at the time named. Fruits which set in the late autumn should not be grown in a high temperature, 65° to 70° during the day being ample and 60° at night. If grown quiet through the winter an increase may be given early next spring, and there will be finer fruits of superior flavour. Plants finishing their fruits should be kept dry. If the fruits be nearly ripe, the bunches may be cut and hung up in a dry, warm house, where they will ripen as required. The strongest suckers should be detached from the plants from which the fruits have been cut and placed on one side, and the old soil and plants should be taken out. Much better results are obtained with fresh soil. Sound loam in a rough state, with such aids as bone-meal and decayed manure, should be employed, with ample drainage, planting firmly and not too deeply, as the Banana is mostly dependent upon surface roots. Suckers not required for planting should be potted up and placed near the light. For free cropping I have found no variety equal to *Musa Cavendishi*. Plants in tubs or large pots will take large supplies of food and moisture if fully grown. It is well with plants perfecting their fruits, to reduce the number of suckers and give a genial temperature, ripe Bananas in October or later being appreciated. Large plants that have failed to fruit should now be kept quiet, as fruiting will be better deferred till early in the year.

**CHERRIES UNDER GLASS.**—The trees should not be forgotten no matter how grown. During heavy rain it is a good plan to empty the tanks on the inside borders. This will assist the trees to plump up the buds. The roots should never suffer from dryness and the leaves be kept as healthy as possible till they fall. With trees in cases not forced there will be later growth. Such trees will well repay liberal supplies of food in the way of liquid manure. Should red spider be troublesome take early means to get rid of the pest by placing a little sulphur in the water when syringing, thoroughly washing all parts of the trees. For black-fly, which often attacks the points, either dip the shoots or syringe with tobacco water. The trees should get free exposure, the ventilators being open day and night. Should the trees be at all gross, omit food, but do not spare moisture. The trees may be prevented growing too freely by root-pruning, and I do not think there is any time better than the present for this work. In root-pruning it is well to proceed cautiously with large or old trees and not to attempt to lift, merely shortening the strong thick roots, carefully preserving all fibrous roots,

spreading these out nearer the surface and giving new soil, such as fibrous loam, to which have been added some wood ashes and old mortar rubble if the soil is at all stiff or clayey. Young gross trees should now be lifted. It may also be necessary to replant nearer the surface. With young trees it is well not to give rich food, using pure loam with the additions advised for older trees, thoroughly watering after replanting, and in bright days damping overhead several times daily to prevent the foliage from flagging, also shading for a short time daily if necessary. In lifting young trees endeavour to get a large ball and well saturate with water if the roots are dry.

G. WYTHES.

### THE KITCHEN GARDEN.

**LATE VEGETABLE MARROWS.**—Although we do not expect sharp frosts at present, the careful cultivator must be on the alert, as for several nights past the thermometer has run down very low. Those who value a late supply of Marrows will do well to provide a temporary shelter for late planted beds. A rough framework answers best, as then it is an easy matter to throw mats or canvas over it if deemed necessary. It is astonishing how late Marrows, that have not been impoverished by over-cropping during the summer months, will continue to yield fruit if well mulched and assisted with liquid manure. Where the advice given to raise a late batch of plants was acted upon, they will only now be coming into free bearing, and certainly such are well worth a little extra labour in the way of protection from frost. Where a special lot of plants was not raised for late fruiting, several of the healthiest and most promising of the ordinary summer fruiters may be freely thinned out, all old straggling main growths being cut well back—this process allowing of another good mulch of rotten manure being applied. Plants so treated will grow away again vigorously and afford many good tender Marrows when the ordinary ones are giving up. Fruits that have been saved for seed should now be detached from the parent plants, and either laid on latticed shelves or suspended in a dry warm vinery at rest for a time to thoroughly mature them. The same may be said of fruit intended for use in pies during winter or for mixing with Apples in tarts, as the practice is in some counties.

**FORWARDING OUTDOOR TOMATOES.**—Batches of plants bearing fruit in a very small state should henceforth be watered with clear water only, applications of liquid manure tending to promote growth rather than to hasten on the fruit. Where any old spare lights from pits or frames are at hand, these may with advantage be placed in a slanting position against the wall in order to hasten on the fruit. Keep all lateral growths closely pinched, and thin out, in strict moderation, the old leaves where crowded. Of course where these lights are used no rain can reach the roots, so that attention must be paid to regular artificial supplies, especially if the plants are in pots plunged in the border.

**TURNIPS—LAST SOWING.**—The first sowing of Chirk Castle or Orange Jelly, if made as advised, will now be fit for thinning. Allow ample room for each bulb, a free circulation of air being absolutely necessary for Turnips that are to stand the winter. Crowded plants invariably have flabby foliage, which gets badly punished by severe frosts. A second and final sowing of Chirk Castle may now be made; this will not only afford good useful bulbs during January and February, but a supply of tender green tops as well, these being much esteemed in the dining-room for a change. If, when the young plants appear above ground, slugs should be troublesome, as they frequently are among late-sown crops, dust well with soot and lime, adding also a little guano to act as a stimulant.

**WINTER CARROTS.**—Sometimes on strong, wet soils Carrots intended for drawing in a small state during winter suffer much from the attacks of slugs and grubs. This difficulty can be surmounted by sowing in a spare frame in a shel-

tered spot and in light friable soil. The roots can then be covered in sharp weather with Bracken or straw litter. All second early sowings of the Horn section may now be lifted and stored in sand or soil in a dark, cool place or even laid in in the open: this will give an opportunity of well dressing the plot from which they have been lifted with gas-lime, as there are few gardens in which Carrots are not more or less affected with wireworm.

**CABBAGES.**—Those who have sufficient ground to risk extra early sowings will now have plants large enough for putting out on permanent quarters. I have all through the season urged the importance of early preparation of all plots intended for either Cabbage or the Brassica tribe, a firm root-run being such a great advantage. However, where this cannot be done, manuring and digging must now take place. I do not advise the use of solid spit manure, rather preferring that in a somewhat shorter condition, but well saturated with the urine. This decays more gradually, much of its strength remaining to benefit the roots in spring, when active growth commences. On no account plant on ground lately occupied with Cauliflowers, or clubbing and a host of other evils, not the least being attacks from the small Cauliflower mite, may follow. A little fresh lime spread over the surface and dug in with the manure, also a little soot, will not only stimulate growth, but also go far to eradicate the greatest enemy of newly autumn-planted green crops—the underground grub. If these early Cabbages were pricked off from the seed beds on to spare plots as soon as large enough to handle, they will lift well with a good ball of earth, especially if a good soaking with water is given through a rose the day before. This should always be practised after a dry period, or no matter how carefully the work is performed the bulk of the soil will fall, tearing off many of the best rootlets with it. Plant with a trowel, and allow a distance of 2 feet between the rows and 18 inches from plant to plant; leave a shallow basin round each, and water home. If time can be spared the best way is to draw drills, watering these well over-night and planting the following morning. Sink the plants well in the ground to prevent swaying to and fro in windy weather. The plants from seed sown about August 20 will now be ready for thinning. Let this be done with a free hand, making those firm to secure better rooting. When large enough I would recommend the pricking-off system even with these successional lots.

**MICHAELMAS CABBAGE.**—This is a term applied to plants grown in some counties for heating in towards the end of September. Secondary plantings from the same seed bed result in useful white heads in October and November, these having a most delicious flavour after receiving one or two moderate frosts. These should now get several good waterings with farmyard liquid, no matter how copious the rains may have been, as at this middle-growth stage the roots draw much nourishment from the soil and need much moisture. Stir by means of the Dutch hoe all vacant places between the rows, not only to kill weeds, but to admit sun and air. If any old summer Cabbages are growing near them and are infested with fly, they should either be done away with altogether or cut right back, or the probability is the above-named lot will also become affected.

**CLEANING AND MOULDING.**—The Dutch hoe should now be put through all growing crops for the last time, as frequent showers have lately induced many weeds to spring up; moreover, if this is neglected at this season they sometimes in the case of a mild winter grow on and seed, leaving an unwelcome legacy for the spring. In exposed gardens the moulding up of any late-planted winter and spring crops, especially Broccoli, must be attended to, as, independent of its steadying the stems, the soil protects the stems from frost. Where procurable, a good quantity of Bracken should be cut in a green state, and when by occasional turnings it has become well seasoned, carted home and stacked. This is in-

valuable during winter for the protection of root crops, Celery ridges, covering frames containing Endive, Lettuce, or other half-hardy subjects, and for mulching fruit trees in early summer.

J. CRAWFORD.

## FRUIT AND VEGETABLE CROPS.

### SOUTHERN.

**The Gardens, Hungerford Park, Berks.**—In this garden and the neighbourhood I find that Apples are rather scarce, about a third of a crop, the summer and autumn of 1894 not having been favourable for ripening the wood. We have a good crop of Peaches on the walls, also Apricots and Nectarines, which were not protected in any way. As for Plums, we have far too many, especially on the Victorias, and any amount of small fruit, most of it very fine. I consider this district very favourable for fruit growing of all kinds, particularly stone fruit, the soil being a fine sandy loam, resting on chalk, but rather strong.

The late severe winter destroyed all the vegetable crops, though the garden is sheltered by tall trees, and the very dry season just past has made it extremely difficult to keep up the required supply.—J. MORRIS.

**Holly Lodge, Highgate.**—Apples abundant, but small. In my opinion the trees have suffered more from red spider on the foliage than from drought at the roots. Pears an average crop, they having withstood the drought better than the Apples, the foliage clean. Plums a very heavy crop and looking well on the whole. Green Gages very plentiful. Bush fruit below the average, except Black Currants, which have been plentiful, but small. Raspberries good both in quality and quantity, Superlative taking the lead. Strawberries abundant and good with the exception of those attacked with mildew, which has been more prevalent this year than I ever knew. Peaches and Nectarines average crop and trees healthy. Morello Cherries plentiful, but small, having been affected by the dry season.

The severe winter was most destructive to shrubs and vegetables, but not much perceptible damage has been done to fruit trees.—J. WILLARD.

**Arundel Castle, Sussex.**—Apples average crop. Lord Suffield, Lanc's Prince Albert, Cox's Orange Pippin, Cox's Pomona, Mr. Gladstone, Stirling Castle, Northern Dumpling, Cellini Pippin, and Keswick Codlin are carrying heavy crops. Trees are very clean. Pears under average. Pit-maston Duchess, Beurré Bosc, and Marie Louise are carrying best crops. Plums average on walls. Green Gage, Imperial Gage, Orleans, Kirke's, Victoria, and Royal Dauphin are carrying good crops. Apricots, Peaches, and Nectarines average crops, trees healthy and fruit colouring well. Cherries, both sweet and Morello, average, quality very good. Strawberries over average, but fruit small. Raspberries abundant, but canes suffered from the severe frost. Gooseberries under average. Currants, Medlars, Filberts, and Walnuts good crops.

First and second early Potatoes are yielding medium crops of good quality; late kinds are growing out since the rain came. Peas, Beans, and all Brassicas have to be constantly watered to keep them going. From April 1 to July 17 we had 4½ inches of rain, from July 18 to 30 we have had 3½ inches.—E. BURNEY.

**Betteshanger, Dover.**—Although such a dry season nothing seems to have suffered. Shrubs looked badly cut up for a time, but have now quite recovered. Roses did not suffer so much as might have been expected. Though late in breaking, they bloomed well. All kinds of bush fruits are very plentiful. Pears and Apples plentiful. Peaches and Nectarines good. Plums and Damsons scarce. Figs, very much cut at first and very late in coming into leaf, are now show-

ing a lot of fruit, so that if we get a good August there will be plenty of fruit.

All vegetable crops are looking well. Potatoes are showing no trace of disease. Peas have been good on all trenched ground, especially all the first sowings. I find the recent rains have done the late Pea crop a deal of good.—JOHN SELWAY.

**Hillingdon Place, Uxbridge.**—After such a wet, sunless summer and autumn as we experienced last year the wood of fruit trees was very imperfectly ripened. Followed by the very severe frost, prospects for this year's crops were anything but bright in the early spring, but after all, comparatively little injury was done to fruit trees. Peaches on a south wall have done remarkably well, setting a prodigious crop so far of excellent quality. Cherries set well. Although many dropped during the stoning period there is still a heavy crop. Apricots, Plums, and Pears are with some exceptions rather below the average. Damsons are a full crop. Apples, on the whole, will be very good, notwithstanding a considerable quantity fell from the trees in a small state owing to the long-continued drought. The heavy rains we have had during the last few days have helped them greatly, and all fruits are now swelling rapidly. Bush fruits are abundant, but small. Strawberries and Raspberries large, plentiful and good. All trees and bushes have been very clean and free from insect pests.—J. GRANDISON.

**Fulham Palace, London, S.W.**—Apples bloomed well, set well, and grew away very quickly till nearly the end of the dry weather, when they began to fall. The rain came in good time, and since that they are holding on well and are an excellent crop. Pears are also good. Plums, only a few trees here, and on them only an average crop. Peaches a very good crop. Gooseberries and Black Currants an enormous crop, large and good. Strawberries an excellent crop and held out for a very long time.

Potatoes an excellent crop, and although we had no rain from the time of planting till some were fit to dig, the crop was good in every way, Early Puritan being the one for early, The Gentleman, Prodigious and Imperator following: these late ones, owing to the late rain, are very strong and show every appearance of an enormous crop. Tomatoes were all planted out when 18 inches high from 9-inch pots. By so doing they had a good start. They have been setting the fruit from the time they were planted out, and now the first set fruit is daily ripening and of good size and quality.—A. J. BALLIANTINE.

**Hume Towers, Bournemouth.**—I have had a very good crop of small fruits. Black and Red Currants I never had finer. I have a good crop of some sorts of Apples, such as Lord Suffield, Manks Codlin, King of the Pippins and American Mother. Pears are very scarce; there was a good set, but nearly all fell from the want of moisture to swell them off. I have noticed the same thing other years when dry at that season.

The vegetable crop has been very poor. Peas only half a crop. Cabbage and other things very small. I have not had a good Cauliflower this season, but there is a vast improvement in everything since we got rain. The severe winter did not do so much damage about here, as in other places with the exception of killing a few shrubs.—W. EARL.

**Eaglehurst Castle, Fawley, Southampton.**—Strawberries were a very good crop and the flavour very good, although the plants had every leaf killed through the very severe winter. The soil here is rather light, but by trenching the ground and well manuring, Strawberries do well. Gooseberries and Currants are also very heavy crops, and, considering the dry weather we have had, the fruit of fair size. Raspberries are a very good crop. The rain we have had has greatly benefited them and the fruit is now swelling well. Apples and Pears are a very heavy crop, but many fruits fell owing to the dry season. Apricots are the finest crop I have seen for many years, the fruit requiring a good deal of thinning. Peaches

and Nectarines on the walls are not such a good crop this season. The trees were much affected this season with blistered leaves. Figs do remarkably well here outside in favourable seasons, and I believe we have some of the largest Fig trees in England. Plums are a very good crop both on the walls and on standards. Plums do very well in orchards in this neighbourhood. The soil, generally speaking, is light, but of good depth.

Vegetables are excellent this season, with the exception of Peas, which have been very much blighted.—H. GARRATT.

**Woodhatch Lodge, Reigate.**—Apples are over average and the fruit promises to be very fine. Pears under average. Raspberries under average, but the fruit is very fine; the frost injured a great many of the strongest canes. Currants (Red and Black) a good crop, the Red an especially fine crop. Gooseberries good crop and all varieties fruiting well. Strawberries promised well, but owing to the drought the crop was a short one. Nuts good crop. Plums under average.

Potatoes are looking well and no signs of disease at present. Root crops are looking well. Onions are free from maggot and swelling well. Peas have done well, Veitch's Main Crop, Stratagem and Webb's Senator being very fine.—C. J. SALTER.

**Bulmershe Court, Reading.**—Strawberries were very fine. I gave the plants one good watering just as the fruit was changing colour, and that helped them through the dry weather. Apples are rather scarce on garden trees, but there is a better crop on the orchard trees in the neighbourhood. Our garden trees were badly attacked by the Codlin moth, and that I think is the main cause of many failures. Peaches and Nectarines a very good crop, also Apricots. Raspberries very plentiful, but small; Pears a fair crop, Gooseberries and Currants (Red, White and Black) very good, Cherries up to the average, Figs very few, Plums under the average.—T. NASU.

**Wilderness, Sevenoaks.**—Judging from present experience and the promise of later crops, the fruit season of 1895 will be one to remember with pleasure, and that after the past severe winter and dry spring. Having a plentiful supply of water, we have been able to preserve our crops, which are now rewarding us liberally. Small fruits are both abundant and of good quality, especially Raspberries, while Strawberries left nothing to be desired, Gunton Park and Lord Suffield being specially fine both in quality and size. Apples are plentiful and promise to be fine. Pears are also good, but Apricots and Plums are under the average.

Potatoes, though small, are plentiful and good, and Peas abundant; the same may be said of other vegetables, proving that where there is no scarcity of water the returns are better from a dry than an over-wet season.—HENRY ELLIOTT.

**Cambridge House, Twickenham.**—Considering the dry season, our crops here have been good. Apricots a fair average crop. Apples (cooking) very heavy and clean. Pears an average crop. Plums on walls above average, but rather small. Bush fruits abundant, especially Gooseberries. The Plum does very well here on our gravelly soil as an orchard tree, but a rather stiff loam would suit it better.—J. E. BURTON.

**Elsenhall Hall Gardens.**—The fruit crop in general is good. The severe winter does not seem to have hurt the fruit trees. Strawberries looked like producing a very heavy crop, but the season was much too dry. All the other soft fruits were good. Cox's Orange Pippin Apple is bad with me. Last year the trees lost their foliage early from the frost and insects, but now they are making good wood. Pears are fairly good, and Plums are a first-rate crop.—W. PLESTON.

**Basing Park, Alton.**—Apples are a good average crop, the fruit large and clean, and two or three weeks earlier. The trees also are clean and have made good growth. Pears much under average and small on standard trees, but on the wall trees a good crop and large. Plums a good

crop. Cherries good, the trees clean and healthy. Peaches and Nectarines good and much earlier. Apricots good crop. Gooseberries thin crop. Currants good, fruit large and clean. Raspberries most abundant crop, fruit small, through so much dry, hot weather. Strawberries almost a failure, through the hot and dry season and frost at night. Nuts most abundant.—W.M. SMYTHE.

**Great Brickhill Manor, Bletchley.**—The severe winter through which we passed was anything but detrimental to fruit trees; on the contrary, I have never had better crops. Strawberries coming first into season were far above the average in quantity and quality. I never in all my experience remember seeing such a show of bloom followed by an extraordinary set of fruit. Copious watering during the drought very materially assisted in swelling off an enormous weight of fruit. As to sorts which hold their own, J. Veitch takes the lead; no other variety that I know can approach it for its robust constitution, its never-failing cropping properties, and its noble and handsome appearance combined with good quality. I still grow Keens' Seedling, Laxton's Noble, Cardinal, and several others which are all very good in their way. I have a good opinion of Royal Sovereign, and I think when better known it will take a leading place. Bush fruit, Gooseberries and Currants very heavy crops and excellent in quality, the trees being healthy and perfectly free from blight. Raspberries are not so heavily cropped, but good in quality. Apples far above the average, all sorts being abundantly cropped, while the trees are quite free from blight. Pears are more variable.—G. BLOXHAM.

**Easton Lodge, Dunmow.**—Apples here are a good average crop; some kinds are bearing heavy crops, especially Keswick Codlin, Warner's King, Blenheim Orange, King of the Pippins, Cox's Pomona, Nelson Codlin, Lord Suffield, New Hawthornden, Dumelow's Seedling, Irish Peach, Devonshire Quarrenden, Mère de Ménage, Ecklinville Seedling, Lady Henniker, and Manks Codlin. Pears are rather a light crop. Plums are under average: Early Prolific, Victoria, and the Mirabelle are carrying heavy crops. Cherries average crop; Morellos a heavy crop. Peaches and Nectarines of all kinds are good. Apricots poor. Small fruits were an average crop. Raspberry canes were greatly injured last winter by the severe frost. Strawberries were over average, but rather small.—H. LISTER.

**Yattendon Court.**—The past season has been a record one, and for a parallel we must go back to 1854, when the troops were in the Crimea. Winter commenced in real earnest with the new year and lasted till the 12th of March. The winter of 1854 began the first week in February and lasted till April. Most of our green vegetables were destroyed, and for a time our vegetable supplies consisted largely of roots, as Parsnips, Celery, Salsafy, Scozonera, &c. The hardest green vegetable is the Leek, which never fails in the most severe season. The Spinach lived and did well and I saved some of the spring Cabbage on the old Onion bed, which has, in spite of the season, produced three crops. With the exception of Cauliflowers, our vegetables are good all round. On June 26 we had a splendid rain which saved the crops. We had 1·25 inches fall in an hour. Our Potatoes are good, and at present I have seen no trace of disease, but the present weather is likely to produce it. Apples nearly a failure, Pears very few, Cherries a fair crop, Morellos good on walls. Small fruit, Gooseberries, Currants, Raspberries and Strawberries, of each a good crop. After the very severe winter we passed through, and which lasted so long, I had hoped that the severe weather had destroyed most of the insect pests that affect fruit trees, Apples especially. I am sorry to confess that we have never had a worse visitation of insects on fruit trees, and that in spite of applications in the spring of No. 2 remedy on the leaflet sent out by the Board of Agriculture. I have come to the conclusion that only arsenical compounds are destructive to the enemies of the

Apple. I found the above remedy very effectual for the destruction of black fly on Cherries.—R. MAHER.

**Otershaw Park, Chertsey.**—Apples are a good average crop and the fruits are swelling well since the rain. Pears are much under average. Plums are an average crop on walls, but in the open thin. Cherries have been an average crop both on walls and on standards, and the trees have not suffered from fly this year. Peach and Nectarine trees look very well, the fruit swelling gradually since the rain. Red, white and black Currants, Gooseberries and Raspberries have been a grand crop, fruit large and of good flavour. Strawberries, especially the early kinds, were a grand crop, fruit large and of fine flavour. The late fruit was small from want of rain, and in some places the plants were destroyed.

Vegetables have all suffered more or less from want of rain, but are beginning to look better now. Early Potatoes have been small but the flavour was good. Late ones look very well indeed, and I have not seen a bad tuber this year.—THOS. OSMAN.

**Englefield, Reading.**—The fruit crop here, I am happy to say, is very good. Bush fruits, such as Gooseberries and Currants, have been very abundant. Apples are good. Pears good. Plums fair crop. Apricots plentiful. Peaches good. Early Strawberries were good, but late kinds suffered much from the drought.

Vegetables are now looking well, but during the dry weather Peas suffered very much, and a supply could not be kept up. We have no sign of Potato disease yet. Our lowest reading of the thermometer was 3°, which equals 29° frost.—JAMES COOMBS.

**Bearwood, Wokingham.**—The fruit crop here and in this neighbourhood is a good average one. Apples are an immense crop. Pears on wall and standard trees under average. Plums thin in places, more so on walls; some standard trees are carrying very heavy crops. Peaches and Nectarines excellent. Apricots, not grown much in this part, are under average. Bush fruit suffered much from the great heat and drought, in places fairly good crops. Strawberries the same. Our early Potatoes turned out good. Later sorts promise well, and are at present free from disease. Most kinds of green vegetables, early and late, are excellent.—JAMES TEGG.

**Brookwood Asylum, Woking.**—Apples are abundant generally. I have been obliged to prop up the branches. Pears are very thin generally, as the trees were exhausted by the heavy crops of 1894. Plums are very heavy on the trees in the low ground, owing to the rest they got last year through the frost destroying the bloom, but on the high ground, where the yield was so abundant last year, the crop is thin. Bush fruit was plentiful and good, but suffered a little from the drought. Strawberries abundant, but would have been much finer with more moisture. Apricots rather thin. Pears thin. Nuts a fair crop.—R. LOYD.

**Mentmore, Leighton Buzzard.**—Apples an excellent crop on all trees, both in gardens and orchards. The early varieties, such as Mr. Gladstone, Beauty of Bath, Red Quarrenden, &c., have been of very fine quality and highly coloured. The trees are very healthy and have made fine growth considering the dry season. Pears and Plums are also a very heavy crop. Strawberries have been of good quality and a fine crop where the plants were watered. British Queen has been very fine this season, also Waterloo and Laxton's Latest of All. Small fruits have been abundant and of good quality. The past hard winter has done the hardy fruit trees a great amount of good by killing nearly all insect pests. The trees have never been so healthy as they are this year.—J. SMITH.

#### WESTERN.

**Badminton Gardens, Chippenham.**—The fruit crops in this garden and neighbourhood are, on the whole, very good, Apples especially so,

all kinds being well represented. Cox's Orange Pippin is particularly fine and abundant. Pears are not so good as last year. Plums are a good average crop, many of the best sorts requiring thinning. Apricots are very capricious this season, some trees well loaded with fruit, others usually prolific have none; the cause of this is not apparent. Strawberries and bush fruits were very good indeed, especially where liberal and deep cultivation had been given. The frequent recurrence of long periods of drought during the spring and summer necessitates exceptionally generous cultivation if results are to be at all satisfactory. The past severe winter had no harmful effects on fruit trees that I can detect, except in the case of Figs that were unprotected. The Nut crop is a good one, Walnuts especially so.—WILLIAM NASH.

**Trelissick, Truro.**—Apples will be a very light crop in this district; the trees blossomed and set abundantly, but weak, so that many of them cast the whole of their fruit early in June—caused no doubt by the severe and continued easterly gales in early spring. Cox's Orange, Mère de Ménage, Stirling Castle, Sturmer and King of Pippins seem to have stood best. Pears are plentiful, but will be very small. Peaches and Nectarines a splendid crop, the trees unusually clean and healthy. This is not a good Cherry neighbourhood, but some of the trees have borne good crops this year, especially May Duke, Black Heart and Governor Wood. Plums are the worst crop I ever remember. There are many extensive Plum orchards in this district, but none of them have more than a tenth part of their usual crop. Bush fruits have been especially fine and abundant. Superlative Raspberry has been grand, and strikes one as being the best all-round variety grown. Strawberries have been very good, especially John Ruskin, Noble and Sir Charles Napier. Medlars and Quinces are very plentiful. The humid climate of west Cornwall does not suit Apricots, and though I grow a few trees I seldom get any ripe fruit.

Vegetable crops are generally very good, especially Peas, where they have been assisted with a little liquid manure. Potatoes are very good both in quantity and quality. I commenced lifting out of doors the second week in June and never had a better lot. Late crops promise well, and so far (July 25) I have not seen any signs of the much-dreaded disease.—W. SANGWIN.

**The Gardens, Tregothnan, Cornwall.**—The fruit crop here is very good, all bush fruits more than average crop, especially Raspberries, Superlative being the chief variety grown, and of this I cannot speak too highly, it being a heavy and a good successional cropper, with large fruit of excellent flavour. Apples in most places are very plentiful. Cherries (Morello) heavy crop. Pears are very scarce; the trees bloomed well, but the fruit did not set well. Plums scarce. Peaches a good crop and trees clean. The syringe had to be used liberally to keep down red spider, which was very troublesome this season. Strawberries suffered very much from drought, so the crop was very light.—W.M. ANDREWS.

**Abberley Hall, Stourport.**—There is little to find fault with in the condition of the fruit crops generally in this garden and neighbourhood. The staple soil of Worcestershire is of a sandy loam overlying the old red sandstone formation, although this does not apply to the soil of this garden, it being a cold marly clay on the carboniferous limestone, also being at a high elevation. This possibly may be the reason why the fruits and other crops have not suffered so much from the drought as reported from some other counties. Apples are a splendid crop, this being general. The blossom opened well, and with a remarkable freedom from blight there was no check to the embryo fruit. Pears are a fair average in some gardens, but in others much below. The Pear apparently requires a warmer season than 1894 to perfect the fruit-buds. Last season's crop of Pears was the outcome of the thorough ripening of the trees received during the pre-

ceding season, and which as results proved was too hot for Apples. Last season suited the Apple trees admirably, as present crops testify. Plums are a heavy crop and the trees remarkably clean both in the open and against walls. Plum aphid is conspicuous by its absence, and I never had less trouble with the trees than this season. They were washed certainly early in the season as a preventive of insect attacks, as I believe in the old adage "prevention is better than cure." Damsons are about the heaviest crop I ever remember, the trees everywhere breaking down with the weight of fruit. Cherries again are a remarkably fine crop; large quantities are grown hereabouts by farmers for market. Morellos are a very heavy crop and the fruit fine. Our trees are the same year after year, so this season's heavy crop is not the outcome of a light crop the preceding season. Peaches and Nectarines set enormously, and the trees, perfectly clean and healthy, will be sure to swell off fine fruits. Apricots are a light crop, but there was little or no maggot to fight against. The trees in this garden are planted against a wall with a western aspect; consequently the wood was not ripened sufficiently to produce good blossom. Strawberries were the most satisfactory crop I ever remember. The plants are destroyed after the second season. The plants were watered about three times, directing the water into the centre of each plant. No doubt without this watering the plants would have collapsed, as the drought was at its highest at this period. Gooseberries are good, so also are Raspberries as well as Red and Black Currants. The blossom opened strongly and the quality of the fruit is excellent; in fact, I never had it so satisfactory. Walnuts are simply a mass, three to four to a bunch at the end of almost every terminal shoot. The past severe winter evidently did not do the least harm to our fruit trees and bushes; possibly a deal of good, in ensuring the trees having a thorough rest and clearing away aphid.

Excepting Peas, I have no fault to find with vegetables. The drought even on our heavy soil has been too much for Peas, although mulched and watered. The first earlies were very fair, but second crops not so good. Potatoes are very satisfactory, although the first earlies are a light crop on light land. Second earlies are excellent, and main-crop varieties are looking exceptionally well. Onions are looking capitably.—A. YOUNG.

**Rood Ashton, Towbridge.**—On the whole fruit crops here are very good, especially taking into account the unfavourable nature of the season. Apples are a heavy crop, and require in some cases a severe thinning. This is particularly noteworthy in Lord Sunfield, Lord Grosvenor, Stirling Castle, Ecklinville Seedling, Warner's King, Rambour Franc, and London Pippin. Adams' Pearmain, Duchess of Oldenburg, Golden Pippin, Blenheim Pippin, Tower of Glamis, Lane's Prince Albert, King of Pippins, Cox's Orange Pippin, Golden Noble, Cobham, Leyden Pippin, and Wellington all have full crops. Pears are not generally bearing an average crop, some being very light indeed. The best bearers are Burre Hardy, Williams' Bon Chrétien, Pitmaston Duchess, Marie Louise, Gilgil, Althorp Crasane, Marie Louise d'Uccle, Burre Capiament, Emile d'Heyst, Doyenné d'Ete, Thompson's, Easter Burre, Danmore, and Ne Plus Meuris. Plums are under the average, but Pond's Seedling, Coe's Golden Drop, Green Gage, Victoria, Early Orleans, Kirke's, Early Prolific, and Prince Englebert may be mentioned as bearing a full crop. Cherries both of dessert and Morelle kinds have borne extremely heavy crops, and are quite free from aphid. Bush fruits have been very abundant. Gooseberries, of which there has been frequent complaint as to the shortness of the supply, are with me a heavy crop. Red, Black, and White Currants have also been good. Raspberries suffered very much through the severity of the winter, many canes being killed almost to the ground, but this loss has been made good to a large extent by the free-bearing of the young sucker growths. Some very fine fruits have been gathered since the rain, which, happily, came

just in time to prevent the pending collapse, threatened by the severe drought. Strawberries promised an abundant supply, but the tropical weather and an entire absence of water reduced the bulk quite one half. The quality, however, was good, and the troubles consequent on a wet or showery season from slugs and other insects almost unknown. Sir Joseph Paxton, President, James Veitch, Alice Maud, Noble, and Laxton's Latest of All were our best. The last-named was invaluable, and furnished dishes of good fruit after all others had gone. Peaches, Nectarines, and Apricots are an average. Filberts and Walnuts an abundant crop. The foliage of Peach trees was badly blistered in the early spring, but good growth was made later, and is now quite free from insects.

Early and mid-season Potatoes are excellent both in point of crop and quality, Snowdrop and Beauty of Hebron yielding a sack to the red. Late ones look well in the stalks, and the recent rains following on such a drought have set up a few secondary growths in the tubers. Onions, Vegetable Marrows, and Peas are attacked with mildew, the last suffering badly from want of root moisture, the crop, as a consequence, being light and of short duration. Globe Artichokes were much crippled by the intense frost, and the spring Cabbage crop reduced one half from the same cause. Cauliflowers, French and Runner Beans have done remarkably well, the season apparently suiting them. Considering the great extremes of the winter and summer and the plague of slugs in spring, the garden crops must be taken as very satisfactory.—W. STRUGNELL.

**Glewston Court, Ross.**—The past severe winter did not injuriously affect any of the fruit-bearing trees or plants, and the crops, on the whole, are very satisfactory. Apples in our plantation of bush trees are a very heavy crop, all varieties bearing profusely. Plums are also an excellent crop. In the middle of June the drought was beginning to affect these dwarf trees, and we irrigated the whole ten acres by means of steam engines, pulsemeter pump, and hose until we had conducted over one million gallons of water over the plantation. The result of the same is healthy trees bending down with very large fruit, some of which we have been consigning to market daily since July 10. Standard trees in orchards are variable, some bearing good crops and others scarcely any. Cider Apples are a heavy crop. Pears are a poor crop generally both on walls and in the open quarters. Plums good in every respect. Damsons a very heavy crop. Bush fruits have done remarkably well with the exception of Raspberries, which have not been up to the average. Strawberries a fair crop. Cherries of all sorts excellent. Nuts an average crop, but Walnuts the heaviest crop I ever saw. Apricots, Peaches, and Nectarines the best we ever had: the first particularly set so freely, that great quantities had to be pulled off the trees.—S. T. WRIGHT.

**Tortworth.**—With very few exceptions the fruit crops in this district are very satisfactory. Apples are a good average. Cider fruit much over average. Pears are under average, but very clean and good. Plums are a fair crop, particularly the earliest varieties. Cherries abundant and fine. Peaches and Nectarines quite an average crop; the trees have given less trouble to keep clean this season than for many years past. Apricots under average. Apricots do not do well on our soil, whilst a few miles away on the Cotswolds the Apricot does admirably. Small fruits have been most abundant and good. Strawberries very fine and their season a long one. Filberts and Cobs very abundant, also Walnuts. Quinces and Medlars over average and very good. The fruit crops on the whole and generally speaking are much better this year than we have had for many years.—T. SHINGLES.

**Wilton House, Salisbury.**—Apples heavy crop, quality good. Apricots very heavy crop, quality excellent. Cherries heavy crop, quality good. Currants heavy crop. Figs average crop.

Gooseberries heavy crop. Nectarines and Peaches very heavy crop, quality excellent; early varieties ripe on south wall, unprotected, July 16. Nuts and Filberts average crop. Pears under average owing to unfavourable weather during the blossoming period. Plums average crop. Raspberries very heavy crop. Strawberries heavy crop. Walnuts average crop.—T. CHALLIS.

**Toddington, Winchcomb.**—Apples are a very heavy crop. The same may be said of Plums, Peaches, and Nectarines. There are good crops of Pears and Cherries, also of Strawberries, Gooseberries and Currants. Raspberries are rather a poor crop. The hot dry weather appears to have been beneficial to Apples, Pears, Plums, and Peaches. Although a quantity of the former have fallen, there are still heavy crops and the trees look healthy. Currants have been finer than usual. Strawberries felt the effects of the drought and are rather small. Raspberries are the least satisfactory, the canes having been injured by the severe frost last winter. One noteworthy feature of the season has been the almost entire absence of aphid.—J. CLERE.

**Mount Edgcombe.**—We have a very abundant crop of all kinds of fruit this season. We have not suffered much from the drought, having had occasional thunderstorms, accompanied by nice showers. The only crop affected by the dry weather was the early Strawberries.

Seeds of all sorts came up well and vegetables are looking splendid, especially Peas and French Beans. Potatoes as yet are not showing any signs of disease and the crop will be a very good one.—S. J. RICHARDS.

**Old Sneed Park, Bristol.**—I have been here six years and never saw such a fine crop. The gardens open towards the south, and we are very short of water, so Strawberries and Raspberries suffered very much. I never saw such a crop of Strawberries as there was in the neighbourhood, although I have lived in Kent where they do so well. Pear, Plum, and Apple trees are loaded, and the branches are breaking down with the weight of fruit. We have three Fig trees, covering a wall 12 feet high and 140 feet long, but on account of the severe winter we shall get but few Figs. There is a heavy crop of Walnuts.—JOHN KENT.

**The Nssh Gardens, Kempsey, Worcester.**—There are good crops of almost all kinds of fruit with the exception of Pears, which are very thin. Apples are very abundant. There is an average crop of Plums and over the average of Damsons. Strawberries have been a heavy crop, also all kinds of small fruits. Apricots, Peaches, and Nectarines are a good crop on walls where they have been well watered and mulched.

Other crops look fairly well, especially since the rain we have had, which commenced on July 18, just in time to save the late Potatoes. On this light soil we suffer very much from the Onion maggot, and I tried sowing sulphur in the drills, which I had seen recommended, but do not see any benefit thereby. Tomatoes are a splendid crop outside on walls and open border, but want sun now to ripen them up. Late Potatoes look well; early ones have been much smaller than usual, but good.—JOHN JUSTICE.

**Astley Hall, Stouport.**—There is a heavy crop of Apples and Damsons. Plums are good in places, but not general. Pears are very light about here. Small bush fruit has been very good, especially Red Currants, which in many cases only realised three farthings per pound for the grower. Black Currants have been very small owing to the dry season. The Raspberry and Strawberry crops have been very good.

Vegetable crops have suffered very severely this season. All summer vegetables have suffered from the dry weather, but the late showers have done much good and given a good start to all autumn and winter vegetables.—T. BORRER.

**Coker Court, Somerset.**—Apples are a very heavy crop. Apricots, Peas, and Plums moderate. Peaches out of doors seem to be good everywhere. The Gooseberry crop is very vari-

able. In some gardens the trees are loaded, whilst in others there is no fruit whatever. Raspberries, Currants, and Strawberries have been a good crop in most gardens. Walnuts are plentiful.—SAMUEL KIDLEY.

**Ashton Court, Bristol.**—Small fruits have been very plentiful in some parts of this district, while in others they are very scarce. Strawberries carried very heavy crops where planted on level ground. Raspberries have been very similar to Strawberries. I at one time thought there would be very few, as they were very slow in making growth, and a great many canes died back half their length. The rain came just in time to assist them, and was the means of them bearing some good fruit. Currants have borne heavily in these gardens, while only about a mile distant I saw many bushes with very few fruits on them; the lightest crops were on light soil, and in some of the market gardens the summer pruning is neglected, which I consider is a great mistake. Gooseberries have been very light generally. During the severe frost of last winter the birds did great damage to the buds. The only variety that escaped is a variety Cockspar by name. This probably is a local name, as I have not heard of it before. It resembles the Ashton Red or Warrington both in growth and fruit. I cannot speak favourably of Cherries; the soil is too wet, cold, and heavy for them. I saw a few days ago some splendid trees of Morello carrying a heavy crop of fruit; these were on higher ground and the soil light. Pears are almost a failure this year around here. Some of the Apples are looking well, especially Codlins, and the trees are laden with clean fruit. I have seen a good number of young trees on the Paradise which are carrying splendid crops of fruit for their age. When grafted on the Paradise they come into bearing much quicker than those on the Crab, although the trees will not stand the number of years. It is very noticeable that Apples are not colouring so well this year as usual. Worcester Pearmain, Quarrenden, and other bright varieties are still looking very green.—HERBERT NOBLE.

**Compton Bassett, Calne.**—Apples are very plentiful on some trees, but poor on others. Pears are a very heavy crop, Marie Louise, Louise Bonne, Doyenné du Comice, Pitmaston, Beurré Diel, &c., being very heavy. Peaches and Nectarines are a wonderful crop. Waterloo, from which we are gathering large supplies, is of good flavour, more so than usual. Plums are an excellent crop. Cherries are a heavy crop and of good quality. Gooseberries heavy, also Black, Red, and White Currants. Raspberries good. Strawberries the best I have had here in seven years. Damsons scarcely any. Walnuts and Cobnuts very heavy. Medlars and Quinces light.

The Potato crop promises to be excellent as regards the early varieties, being both heavy and of good quality. Later varieties look very promising, with no trace of disease at present.—W. A. COOK.

**The Gardens, Bicton, B. Salterton.**—The fruit crops, taken as a whole, have been, and are, very good. Apples are a very heavy crop and, with the late rain, promise to finish well. The kinds I find best here are Court of Wick, Cox's Orange, Blenheim Pippin, Hawthornden, King of the Pippins, Lord Grosvenor, Peasgood's Nonsuch, Scarlet Nonpareil, Devonshire Quarrenden, Lord Suffield, Sandriogham, Baumann's Red Reimette, Warner's King and Syke House Russet. Pears are an average crop; the best are Beurré Bosc, Beurré d'Amanlis, Beurré Diel, Bon Chrétien, Duchesse d'Angoulême, Gratioli of Jersey, Forelle, Jargonelle, Louise Bonne of Jersey, Marie Louise, Marie Louise d'Ucele, Ne Plus Meuris, Pitmaston Duchess, Van Mons Leon Leclerc, and last, but not least, Doyenné du Comice; the two last I consider the best Pears. Plums are bearing well, most of them against walls. I have them facing east, west, north and south. The best with me are Belle de Septembre, Bryanstone Gage, Green Gage, July Green Gage, laden, and a good grower; Magnum Bonum, slight crop; Early Favourite,

heavy crop, ripe third week in July on east wall; Diamond, good; Golden Drop, laden; The Czar, good doer and good crop; Pond's Seedling and Denyer's Victoria, laden, on north wall; Early Prolific maintains its name this season, as in general; Early Orleans, heavy crop; Washington, thin; Kirke's, good crop; Jefferson, rather thin this year, but one of the best Plums in cultivation, as is also Reine Claude de Bavay, average crop.—JAS. MAYNE.

**Longford Castle, Salisbury.**—The fruit crop for 1895 may, on the whole, be pronounced a good average one. Apricots, Peaches and Nectarines set immense crops of fruit, and therefore had to be severely thinned. I may here remark that trees of Alexander, Waterloo and Amsden June Peaches on the same wall have ripened in the order in which their names appear. Cherries, both sweet and Morello kinds, have borne good crops. Plums, on the whole, are below average, and the same may be said of Pears, of which, however, Marie Louise, Clapp's Favourite, Williams' Bon Chrétien, Beurré Clairgeau, Durondeau, Doyenné du Comice and Glou Moreceau are bearing good crops. Apple trees in orchard, as well as dwarf standards and espaliers in the kitchen gardens, are heavily cropped with good, clean fruit; indeed, the Apple crop for the year 1895 promises to be the most bountiful we have had for several years, and the trees, too, are in good condition. The same remark applies to all kinds of fruit trees here, notwithstanding the unusually severe frosts which we had in January and February last, followed by an equally exceptionally hot, dry summer. Gooseberries and Currants have been heavily cropped. Raspberry canes were somewhat injured by the frost, the top 15 inches of growth having been killed; still, they have yielded sufficient fruit for our requirements. The Strawberry crop was a fair one. Figs good on open walls. Walnut trees I do not remember having hitherto seen so heavily cropped as they are this year. Filberts and Cob Nuts are also plentiful.—H. W. WARD.

**Crome Court, Severn Stoke, Worcester.**—Apples of all kinds are a very heavy crop, and the fruit will evidently be of good size, brightly coloured, and very free from grub. Pears on standards are thin, but on the walls a good crop, and, considering the long period of drought we experienced, will be of full size and of good colour. Apricots, Peaches, and Nectarines are also a heavy crop, very highly coloured and ripening early. Amsden and Alexander over; Early York just coming on; Alexandra Noblesse and Grosse Mignonne will be of full size, judging from present appearances. Bush fruits of all kinds were a heavy crop, particularly Red Currants. Plums on walls are a good average crop, but on standards not so good a crop as usual. They are largely grown in this neighbourhood as orchard fruit, and although most all kinds are planted, those in most favour are Rivers' Prolific, Victoria, and Pershore Egg, the last named invariably producing heavy crops, which find a ready sale, both green and ripe. In addition to the above-named the following are extensively planted: Diamond, Orleans, Pond's Seedling, Jefferson, Kirke's, and Green and Transparent Gages. All these do remarkably well here, and many thousands of hampers are marketed annually. Planting continues to increase rapidly, thus proving how valuable the crop is. Our soil is a strong loam resting on yellow marl, and the trees make a good, but not too strong a growth. Damsons are a good average crop, but the fruit will, I think, be rather small. Nuts and Walnuts are a full crop.—WALTER CHILD.

**Bryarston, Blandford.**—Strawberries were an abundant crop and fruit very fine (but the beds here were heavily mulched and frequently watered, which greatly assisted the swelling of the fruit). The crops in the neighbourhood have been plentiful, but the fruit small. Gooseberries and Raspberries very plentiful and fruit fine. Red and Black Currants good crops, but fruit small. Apricots fair crops, but fruit not so large

as usual. Plums good crops and fine fruit on walls; on standards, &c., in orchards very light. Cherries, Sweet and Morello, plentiful crops. Pears rather below average with the exception of M. Louise, B. Bachelier, Louise Bonne of Jersey, and Beurré Diel; these are carrying good crops. Apples are very plentiful, especially late varieties. Walnuts have never been so plentiful. My impression is had we not had a severe winter fruit would not have been so plentiful; owing to the very mild autumn the trees made such late growth that they could not get properly matured, but owing to the long spell of severe weather everything had a thorough rest.—A. J. ALLSOP.

**Batsford Park, Gloucester.**—None of our fruit trees sustained injury from frost at the period of flowering and many of them have crops almost beyond what they are able to bear. Especially does this apply to Apples of nearly all sorts and of trees of various sizes, large standards in orchards and pyramids in the garden being heavily laden. During the severe weather of last winter much damage was done by birds, especially bullfinches, to the buds of Plums and Gooseberries, and to a less extent Pears, Apricots, &c., and it became necessary to protect with nets. This thinning of buds, although in no case causing failure, has made some of the crops lighter than they would otherwise have been. May and June were dry months and but little growth was made until after the rain came, when the change was remarkable, and most of the trees now look very healthy and are bearing fine fruit. Rarely has there been so little injury on the whole caused by blight and insect pests generally as this season. Wasps are, however, very plentiful and most destructive. Peaches and Nectarines made indifferent growth last year and the wood never ripened properly from want of sunshine, and these crops are not over-abundant. The fruit of the earliest varieties is small; later ones are better, especially Dymond, Royal George, Bellegarde, Grosse Mignonne amongst Peaches, Elruge and Hardwick being the best Nectarines. Apricots were of good quality, but far less in quantity compared with the last two years, when the crops were exceptionally heavy. Moorpark and Large Early are the varieties grown. Early Prolific is the earliest Plum we have and is excellent for cooking, the other varieties bearing best being Webster's, Brahy's, and Bryanston Gages, Pond's Seedling, Cox's Emperor and Victoria. The chief standard Plums in this neighbourhood are of old varieties, especially of Pershore, which has very heavy crops and is used for cooking and preserving. Victoria is also fruiting well as a standard and appears to be one of the best for the purpose. Standard Plums are not extensively cultivated in orchards. Several varieties we planted in this way are making good growth, but are not quite old enough to judge. The best flavoured Plums include the varieties of Gage mentioned above and the old Green Gage, Jefferson, Kirke's, and Cox's Golden Drop. Dessert and Morello Cherries very good, the fruit large and the trees exceptionally free from black fly. Figs were cut hard back by frost and there are in consequence no fruits. Apples, as before remarked, are most plentiful and promise to be very fine. Blenheim Orange and Keswick Codlin amongst large orchard standard trees are quite conspicuous, and garden pyramids of many varieties are pictures, so well laden are they with fruit. Ribston and Cox's Orange Pippin, Irish Peach, Worcester Pearmain, Margil, Court Pendu Plat, Gravenstein, Stirling Castle, Lord Suffield, Tower of Glamis, Warner's King, Ecklinville, Blenheim Orange, and many others have excellent crops. Pears are not so plentiful here as last year excepting a few that invariably bear well and which are used for stewing, Vicar of Winkfield for example. Marie Louise, Doyenné du Comice, Emile d'Heyst and Thompson's are thin, but the fruits promise to be fine. A variety which succeeds well as a pyramid on the Quince stock is Conseiller de la Cour; it bears most abundantly. The fruit of Clapp's Favourite, Beurré d'Amanlis and Pitmaston Duchess is very large on pyramids. Strawberries were plentiful, of

large size and excellent quality, and the crop was not badly injured by the drought. The soil being fairly retentive of moisture and the beds mulched with short straw combined to assist the plants in a dry season like this, and in the absence of rain none of the fruit decayed before being gathered. It is a great advantage to have young plants, as the oldest plantations are always those to suffer first from drought. My system is to make a new plantation each year towards the end of August and destroy one of about a similar size that has been longest established, three years being, as a rule, the limit. The four varieties depended upon both for forcing and outdoors are Keens' Seedling, Vicomtesse Héricart de Thury, Sir Joseph Paxton and President. Raspberries were a good crop and of fairly large size considering the dry weather. When about half were gathered the birds devoured nearly all the rest so soon as they turned colour. It seems strange that sometimes they scarcely touch them, but this is also my experience with other garden crops in different seasons. Currants of all kinds were abundant and good. An old Quince tree is bearing well and Nuts and Walnuts are plentiful.

Vegetables in the spring months were scarce here, as elsewhere, in consequence of the severe winter. Many seeds came up very indifferently or the seedlings died off soon after getting above ground. Early Peas did badly and none have really done well so far. Cabbage plants survived the winter, but were a month later than last year in coming into use. Early Potatoes escaped frost and have been good in cropping and excellent in quality. The later ones improved wonderfully after the rains came and at present look promising. Cauliflowers and Turnips have done badly all the season, but Autumn Giant Cauliflower is better. Asparagus did well and the late Argenteuil variety prolonged the season. Tomatoes are cropping heavily on outside walls and beginning to ripen. Celery, Runner Beans, Vegetable Marrows, Brussels Sprouts, and all green crops have been thriving satisfactorily since the beginning of July, and with more favourable weather the vegetable supplies should for the remainder of the season be more easily maintained.—J. GARRETT.

**Iwerne Minster, Blandford.**—We are in the midst of the eighth month of 1895, a year already remarkable for extremes in temperature. The mild autumn of last year seems to have well matured the fruit-buds, for although the long succession of frosts, which began with the year and lasted till the middle of March, wrecking our kitchen garden and leaving indelible marks upon Tea Roses and tender shrubs and trees, did not seem to have hurt the fruit-buds, for with the one exception of Pears, which are a partial crop, I have seldom, if ever, seen a finer show of bloom or a better set of fruit. But the decisive drought in early summer checked the embryo fruits, thinned the crop, and prevented them swelling. Many heavily-laden Apple trees had begun to lighten themselves before the rain came to the rescue. There is still an abundant crop of Apples, and the late rain has done much to swell the fruit. Some of the dessert kinds, such as Kerry Pippin, Quarrenden, and Red Ingestre, are already showing by their red and yellow streaks that they are approaching maturity. Plums are also a good average crop and the trees look healthy. We grow only the well-tried kinds, the old Green Gage and several of its varieties for dessert, also Jefferson, Kirke's, and Coe's Golden Drop. The last will sometimes hang till nearly Christmas. I can find nothing to equal the Green Gage for flavour. Of course all the above kinds require the protection of a wall to bring out their best bloom and flavour. For cooking I grow the red and yellow Magnum Bonum, Orleans, Victoria, and the Czar, which all do well here and in the locality as standards. Bush fruit and Strawberries have carried heavy crops, although the fruiting season of the latter was shortened by the drought. Nuts are plentiful, especially Walnuts.

Peas, Beans, and all other vegetable crops are plentiful and good. Early Potatoes were a light

crop, but second earlies, such as Puritan and Windsor Castle, two excellent varieties, have fine tubers, cook mealy, and are delicious in flavour. Late varieties are looking well, and as yet are free from disease.—P. DAVIDSON.

**Killerton, Exeter.**—Apples are a very heavy crop in all parts both in orchards and gardens; all the fruit is very fine. Apricots have been very plentiful and the trees are very healthy. Cherries have been good; Morellos are now very fine, both in crops and the size of the fruit. Peaches and Nectarines are a heavy crop and trees healthy. Pears are only an average crop. Williams' Bon Chrétien, Comte de Lamy, Passe Colmar, Winter Nelis, Monarch, Beurré Clairgeau, Beurré Bachelier and l'Incennue have all heavy crops. Figs are a good crop on the walls and the fruits are ripening well, two of the most free bearing sorts being Brown Turkey and White Marseilles; the Brunswick is also good. Old trees of the same sorts as bushes or almost standards have suffered

ton's Superb. Filberts, Cobs and Walnuts are plentiful.—JOHN GARLAND.

## TREES AND SHRUBS.

### VINES AS CLIMBERS.

ONE lovely family of climbing plants is little thought of in gardens—the Vine. None is more familiar because grown for its luscious fruit, but it is in the garden, rambling over arches, hiding ugly corners and festooning pillars, as in the R.H.S. Gardens at Chiswick, that we want to see this graceful creeper. The accompanying illustration shows its beauty as a climber, its noble foliage and its charming grace. A Vine leaf is more beautiful in itself than any leaf; then we get the flowing tendrils, the clusters of fruit, pleasing if they never colour in our cold clime, and the glorious leaf tints of autumn.

We all know the richness of a vine in autumn, the ruddy crimson, bronzy purple, and scarlet leaves, mingled together or seen separately, showing a wealth of colour richer and more lustrous than a houseful of flowers. Yet with such resplendent colouring the Vine gives place to the Virginian Creeper and many other common things that one tires of from their constant repetition. Ampelopsis and Vitis are now amalgamated, but there is far more beauty in the true Vine than in the Ampelopsis, especially those ragged rampant kinds whose foliage dies off without a sparkle of autumn colouring. For autumn colouring the Californian Vine (*V. californica*) is unique, its leafage changing to deepest crimson, and the

*Vine growing on a gazebo. Engraved for THE GARDEN from a photograph by Miss Willmott, Warley Place, Essex.*

terribly the last few severe winters in the open ground, although in a high well-sheltered position and only exposed to the south. Currants of all sorts and Gooseberries have been fine and plentiful. Strawberries also have been very good. Raspberries have been only a moderate crop, many of the canes having been killed by the frost. Plums are only a partial crop; the best are Early Prolific, Victoria, Denniston's Superb, Gisborne's, Mitchelson's, Green Gage and Jefferson, the last two sorts, also Coe's Golden Drop, being on walls. Damsons are good; the Chester or Farleigh has to be well supported to prevent breaking down. In the orchard the Plums do well, the sorts are Early Prolific, Green Gage, Magnum Bonum (White), Victoria, Mitchelson's and Prince Englebert, the last-named being generally the heaviest bearer of all. When we have very heavy crops the markets are too glutted to sell at a profit, and I think it more profitable to grow good Apples, such as the Blenheim Orange and Bramley's Seedling. Among the best flavoured Plums are the Green Gage, Jefferson, Coe's Golden Drop and Dennis-

Northern Fox Grape (*V. Labrusca*) is familiar by name in this choice family. Then we get beauty in some form in the Southern Fox Grape (*Vitis vulpina*) and superb leaf colouring in *Vitis Cointetia*, which is one of the newest additions. It has been exhibited a few times, and on each occasion its beauty has compelled admiration. If I were allowed only one Vine I should select this for its handsome broad foliage, which changes to brilliant crimson ere it falls, and creates a garden picture of intense colouring and attractiveness. Japan has given us a noble climber in this Vine. In warm years the Hop-leaved Vine (*V. heterophylla humulifolia*) is covered with a profusion of turquoise-covered berries. I remember a splendid plant of it in Mr. Kingsmill's garden at Harrow Weald, a mass of the small jewel-like berries. This Vine is best on a wall, where we get a profusion of berries. The variety *purpurea* of the common

Vine (*V. vinifera*) has purple-coloured foliage, and the Tinturier Grape, too, is as rich as a colony of flowers in its autumn colouring.

It is to be hoped gardeners will look after the many beautiful Vines and plant them in such positions as the illustration depicts. An interest that we can get in no other way will be added to the garden at all seasons by their use. C.

**Hibiscus syriacus.**—This Mallow does not succeed where the soil is at all mixed with chalk, or indeed where little but clay abounds. A warm sandy loam or peat will grow this shrub to perfection. I grow several plants of three or four distinct colours in a mass in a southern exposure. Even here in the south if the autumn rains set in early and continue many of the blossoms fail to develop properly.—E. M.

## CHRYSANTHEMUMS.

### SEASONABLE NOTES.

THE month of August is a busy one amongst cultivators of Chrysanthemums. In addition to the watering that requires so much care, necessary manipulation of the shoots and buds requires daily attention. Especially is it necessary in growing Chrysanthemums to attend to the requirements of the plants just at a time when required, or failure is certain.

The principal item is now the "taking" of the buds. As fast as these form in the points of the shoots they should be examined, and if found of good form, devoid of any irregularity or blemish, they should be "taken." This phrase is a common one amongst cultivators, but to the inexperienced it may be misleading. It really means removing all growth shoots, so as to concentrate the energy of the whole plant into the swelling of the flower-buds. If the removal of the shoots is deferred for a few days longer than is necessary, they appear to rob the bud of its power of development to such an extent, that it seems to lack power to swell to its normal size, and consequently receives a check. Early in the morning when the foliage is laden with dew, or in the evening, is the most suitable time for bud "taking;" the shoots then being more succulent, they snap off so much more readily than if left until the middle of the day, when they are somewhat limp and flaccid owing to the heat of the sun and a want of moisture in the air. Where large blooms are required, no time should be lost after this date in securing the buds; any plants that are allowed to "run on" after this date will not be very satisfactory.

Feeding the plants should now receive some attention; it is useless to attempt to grow good plants or large blooms without the aid of artificial stimulants of some kind. The Chrysanthemum is a gross feeder. No matter how rich the soil was made at potting time, it is sure to be exhausted very considerably of its nutritious qualities. When the newly-formed buds are seen to be swelling freely, liquid manure made from cow or sheep manure and soot should be freely given. Where the plants are healthy and have fairly well-ripened wood and matured leaves, and the pots not more than 9 inches in diameter, liquid manure in a weak state may be given every time the plants require water. Although the above-named stimulant is one of the best that Chrysanthemums can have, it would not be wise to stick entirely to that kind for the whole of the season. A change of diet is good for Chrysanthemums. After giving liquid manure to the plants for a fortnight continuously, give nothing but clear water for two

days, so as to cleanse the plants as it were. A sprinkling on the surface of any of the artificial manures so freely advertised, following the directions so clearly given with each, will then be beneficial to the plants. Return again to the liquid manure in a few days for another two or three weeks, so alternating the food supply that the plants cannot possibly be "gorged" by any one stimulant. The remarks on feeding the plants are alike applicable to those grown as bushes, trained specimens, or in any other method. During the late and continuous spell of wet weather the foliage on some plants exhibited a tendency to become pale in colour. With the advent of warmer and brighter weather, most of the plants have again assumed their wonted colour. Those not having done so will be all the better for a dose or two of sulphate of iron given in liquid form; 1 ounce dissolved in a gallon of water is a safe quantity to give the plants at an interval of two days. It is really surprising what a quick effect this has upon the colour of the leaves of the plants. Where lime does not exist naturally in the soil in which the plants are growing it is a good plan to occasionally well soak the soil with lime water, adding as much lime to a canful of water as will be held in suspension. When the lime in bulk settles at the bottom of the vessel the water is strongly enough impregnated with lime. Not only is this treatment beneficial to the plants themselves, but the lime rids the soil of worms. Surface roots should be encouraged as much as possible, for these have a decided effect upon the flowering of the plants. When the plants are allowed to become dry too often, a fair quantity of surface roots can seldom be found. Now is a good time to set about the increase of surface roots. Plants that have their buds "taken" are in greater need of assistance at the roots than at any other period of their existence, because of the extra strain of supporting both leaves and buds. A top-dressing of some rich food is obviously the best means of affording additional food and encouraging surface-root action at the same time. No one can err in employing fresh turfy loam, sufficiently decayed to destroy the grass. Two parts of this to one of bone meal, dissolved bones, or any of the different manures advertised will form a good rooting medium if laid on about three-quarters of an inch thick and pressed down firmly. It is a good plan to well soak the loam with liquid manure before using it. Freshly-gathered cow manure mixed with loam in equal proportions provides a good rooting medium. This freshly laid on compost is apt to become washed off the roots in applying water at first, but if a piece of crock is laid upon the soil where the water is usually poured on in watering the plants, this defect will be averted. Mildew is becoming troublesome, attacking the underneath side of the leaves. In mild cases flowers of sulphur dusted on the parts affected is sufficient to stop the progress of the fungus, but in stubborn cases, or where difficult to apply the sulphur in a dry state, the lime and sulphur composition so often recommended should be employed. No one using this antidote need be troubled long with mildew upon the plants if every part is thoroughly wetted. E. MOLYNEUX.

### CHRYSANTHEMUM MME. C. DESGRANGE.

This is still the most useful early variety in cultivation. When grown for large flowers, by disbudbing the shoots and adopting liberal treatment it produces really handsome massive blooms. No one perhaps has been able to produce such splendid specimens as Mr. Blackburn grew and exhibited for several consecutive seasons, but still

I have frequently seen flowers from 5 inches to 6 inches across. Such flowers are highly valued for their purity of colour and graceful formation. To obtain blooms of the dimensions named it is wise to begin early in the season, so that the plant may have a long period of growth. Mme. Desgrange generally provides an ample supply of stout, healthy cuttings, which should be rooted in early autumn before severe weather sets in, as it is not among the hardest of Chrysanthemums. I prefer to strike the cuttings singly in small pots. The plants can be kept dwarf and stout by wintering them on the shelf of a cool greenhouse, and at the approach of spring they should be shifted into 5-inch pots. Use the compost without anything strong in the way of manures in the early stages, the roots being thread-like and tender. Give the plants subsequent shifts, so that at the final potting 9-inch pots may be used, at which time, too, a little concentrated manure should be added to the loam. About the middle of June the shoots, which had previously been trained to one single stem to a plant, may be topped. This item is of much importance. The topping assists growth before buds appear, as this variety has a tendency to give flower-buds in quick succession after the month named. From three to half a dozen blooms may be perfected on a plant, and when the buds are swelling liquid manure should be applied often and weak. Shade when the flowers are opening adds to their purity. Mme. Desgrange again is excellent for outdoor culture, and the plants may be taken up, potted, and placed under glass to flower. It is necessary to keep the roots and leaves moist and in the shade for a few days after lifting. New roots form readily and established plants are soon obtained.

There are three distinct sports from the type. Mrs. Burrell has a soft shade of primrose-yellow; this is an excellent variety. G. Wermig is of a deeper yellow colour; this is perhaps the best of the sports. Mrs. Hawkins produces blossoms of a deeper shade of yellow than either, but the growth is not so robust as in the type or in the other sports. H. S.

## SOCIETIES AND EXHIBITIONS.

### NATIONAL CHRYSANTHEMUM SOCIETY.

THE first show of this society for the present season was held at the Royal Aquarium on Tuesday and the two following days. Dahlias were the leading feature, as little improvement seems to be made in the early flowering Chrysanthemums, most of those exhibited being old familiar kinds. The grand lot of Gladioli from Messrs. Burrell, of Cambridge, was a feature of the show, and among the miscellaneous exhibits, Apples of fine size and quality were largely shown, and hardy flowers in abundance.

### CHRYSANTHEMUMS.

Mr. E. Such, Maidenhead, secured premier honours for twenty-four bunches of Chrysanthemums, three blooms in a bunch, and not less than eighteen varieties. This was a nice fresh lot, comprising chiefly Mme. Desgrange, its sports, and well known pompon varieties. The best twelve blooms of Mme. Desgrange were shown by Mr. S. B. Wheadon, gardener to Mr. Collier, Bickley, but they were not so fine as we have seen this variety. Mr. Webster, Sussex Lodge Gardens, Clapham, was second. For twelve blooms of any large-flowering variety except Mme. Desgrange, Mr. C. Cox, gardener to Mr. J. Trotter, Brickenden Grange, Hertford, was first with an admirable stand containing fine blooms of E. Molyneux, Stanstead White, Richard Dean, Louise, Mme. E. Rey, Edith Rowbottom, and Commandant Blusset. Mr. Wheadon was second. Miss Debenham, St. Peter's, St. Albans, had the best twelve bunches of pompons, securing first prize, but we are sorry to see here again the same craze for size prevails. The shoots shown had been closely disbudded, and the exhibit

was just within the stipulated conditions, namely, three flowers of each. The best six bunches of *C. Lady Fitzwygram* came from Mr. J. Wright, Denmark Road, Camberwell. In the class for six bunches of large-flowered kinds, exclusive of *Mme. Desgrange* and its forms, only one lot was forthcoming, from Mr. Shaw, of Sherwood, Notts, to which the second prize was awarded. Mr. Pagram, gardener at The Whinn, Weybridge, had the best six bunches of any yellow variety, inclusive of *Mme. Desgrange* and its sports. The varieties shown were Mrs. Burrell, George Wermig, and Mrs. Hawkins. Mr. C. Cox was first for six blooms of large-flowered varieties, showing *Miss Anna Hartshorn*, R. Dean, Louise, Edwin Molyneux, *Mme. E. Rev.*, and *W. H. Lincoln*. The best six flowers of *Mme. Desgrange* or its sports came from Mr. Wedekind, Warlock Road, Paddington; whilst the best vase or epergne of *Chrysanthemums* was shown by Mr. D. B. Crane, Archway Road, Highgate, a charming arrangement of flowers and suitable foliage.

#### DAHLIAS.

In the large class for forty-eight blooms, not less than thirty-six varieties, show and fancy kinds, Mr. C. Turner, of Slough, was first with a fine lot of well-finished blooms. The best were *Prince Bismarck*, Mrs. J. Downie, *Gloire de Lyon*, *George Rawlings*, *Seraph*, *Mabel Stanton*, *John Standish*, *Chieftain*, *Dante*, *Maud Fellowes*, and *Mrs. Gladstone*. Mr. J. Walker, of Thame, was second. In the class for thirty-six blooms distinct, the position was exactly reversed, Mr. Walker being first and Mr. Turner second. Mr. G. Humphries, Chippenham, had the best twenty-four distinct blooms, showing a fine regular lot of flowers, and Mr. J. T. West, of Brentwood, was second. For twelve distinct blooms Mr. West was first and Messrs. J. Cheal and Sons, Crawley, second. Mr. J. Stredwick, St. Leonards, had the best twelve blooms in the amateurs' class, Mr. Starling (gardener to Mr. Raphael, Rosecourt, Havering) being second. Mr. Stredwick was also first in two other classes, both for six blooms distinct. The classes for pompons were well filled. In the large and open class for twenty four bunches of distinct kinds, Mr. C. Turner was first with a superb lot. Not a few pompons were shown too large and overgrown, but the flowers in Mr. Turner's stand were what they should be—small, neat, well finished and charming in variety of colour and freshness. The best were *Purity*, *Ganymede*, *Madeline*, *Favourite*, *Nerissa*, *Claribel*, *Diana*, *Douglas*, *Cecil*, *Captain Boyton*, *Mars* and *Madge*. Mr. F. W. Seale, of Sevenoaks, was second, Messrs. Keynes, Williams and Co. and Messrs. Cheal being equal third. The best twelve bunches of pompons, also an open class, came from Messrs. J. Burrell and Sons, whilst Mr. G. Humphries was second. For six bunches of pompons, distinct (a class for amateurs or gardeners only), Mr. J. Hudson, of Gunnersbury House Gardens, was first, and Mr. W. C. Pagram, Weybridge, second.

So great has been the recent development of the Cactus section, that these varieties now make an important section, and they to a great extent monopolise the attention of visitors who care little for the stiff forms of the show and fancy Dahlias. The competition in Cactus and decorative varieties was strong, and we did not see the old decorative type at all, as varieties of the most perfect Cactus form are numerous enough to make up a class alone. In the open class for eighteen bunches, distinct varieties, six blooms of each, Messrs. J. Cheal and Sons were first with a grand lot of flowers, amongst which we noted *Purple Prince*: *Blanche Keith*, yellow; *Matchless*, very dark crimson; *Wilson Noble*, salmon-red; *Harmony*, orange-buff; *Bertha Mawley*, red; *May Pictor*, buff shading to yellow; *Apollo*, red; *Delicata*, pink and white; *Beauty of Wilts*, orange-red; *Ernest Glasse*, purple, and *Kaiserin*, yellow. Mr. C. Turner was second and Messrs. Keynes, Williams and Co. third. Mr. J. Burrell was first for twelve bunches of Cactus-flowered varieties, the following being of note: *Gloriosa*, *Matchless*, Mrs. Barnes, blush; Mrs. Peart, white; and *Lady*

*Penzance*, rich yellow. Mr. F. W. Seale was second. For six bunches in the amateurs' class, Mr. J. Stredwick was first and Mr. G. Wyatt, gardener to Mr. Hilditch, Twickenham, second. Messrs. J. Cheal and Sons were also first for twenty-four distinct bunches of single-flowered varieties, a good lot, but we think somewhat weakened by the presence of several spotted kinds that are poor in effect and valueless in the garden. The best were *The Bride*, A. Perry, *Lowfield Beauty*, *Miss Roberts*, *Formosa*, *Miss Henshaw*, *Demon* and *Rosebank Cardinal*. Mr. F. W. Seale was second. For twelve bunches, distinct single varieties, Mr. E. Such, of Maidenhead, was first and Mr. C. Osman, Sutton, Surrey, second.

The best Gladioli came from Messrs. J. Burrell and Co., who were an easy first with a grand exhibit of about 120 spikes, beautifully fresh and varied, many of them unnamed seedlings of their own raising. *Sunray*, light salmon-red, was conspicuous for the great length of the spike, and *Blushing Morn* was lovely in soft blush colour. Mr. R. Morrow, Leominster, Hereford, was second.

#### MISCELLANEOUS.

The miscellaneous and non-competing groups made up a large portion of the show. Mr. T. S. Ware, of Tottenham, made a wonderful display of Dahlias in all sections arranged in a bold and distinct way, forming a great bank of colour relieved by slender sprays of Asparagus and backed up with Bamboos and tall Grasses. Messrs. Dobbie and Co. also showed Dahlias largely, especially the single Cactus-flowered varieties now to be had in many shades of colour. Mr. H. J. Jones, of Rycroft Nursery, Hither Green, Lewisham, showed a graceful group of Begonias arranged with Asparagus and Ferns and backed up by finely-flowered Chrysanthemums in pots, and from Mr. Norman Davis, Camberwell, came a large group of Chrysanthemums, consisting chiefly of the variety *Lady Fitzwygram*, a really good kind that should become as popular as *Mme. Desgrange*. A group of Lilies and Chrysanthemums was also shown by Mr. Ware, whilst Messrs. J. Laing and Sons showed hardy flowers in quantity and fine Apples. Mr. Such, Maidenhead, showed Dahlias and Pyrethrums. Hardy flowers were well shown by Mr. Prichard, of Christchurch, and *Sweet Peas* by Mr. W. E. Tidy, of Havant. A group of flowering and fine-foliaged plants was shown by the Jadoo Fibre Co., the plants, admirable examples of their kind, all grown in this material. Table decorations were shown by Mr. J. R. Chard, of Stoke Newington, and Mr. G. Williams, of Ealing. A good collection of fruit (Apples, Pears and Melons) came from Mr. Miller, Ruxley Lodge Gardens, Esher: whilst Apples were very extensively shown by Messrs. Cheal, of Crawley, Mr. Spooner, of Hounslow, and Mr. A. Wyatt, of Hatton, Hounslow. Kerry Pippin and Irish Peach in Mr. Wyatt's collection were as fine as we ever remember to have seen these two kinds, and a quantity of each was shown in shallow baskets. The Apples all through were conspicuous for size, high quality and good colour.

**Vegetable show at Chiswick.**—The next meeting of the Royal Horticultural Society will be at Chiswick Gardens on Tuesday, Sept. 10. Prizes are offered in forty different classes for vegetables, and a good show is anticipated. Besides vegetables, however, the usual collections of hardy plants, Orchids, cut flowers, fruit, &c., will also be received at Chiswick, and any new or rare specimens will be examined by the various committees, which meet at 12 o'clock noon. At 1.30 there will be a vegetarian luncheon arranged by Mr. A. Hills, President of the Vegetarian Federal Union, and at 3 o'clock a lecture on "Garden Manures" by Mr. W. G. Watson will be read, and a discussion invited thereon.

**Wasps.**—Mr. Crawford must be favoured as to the presence of wasps, as here they are numerous. I have taken no less than ninety nests within a quarter of a mile of the garden. I find cyanide

of potassium by far the most effective means of destroying the nests. I do not find that those wasps which are out during the daytime escape even when the nests are taken then. A visit to the nests two or three days afterwards does not reveal any flying about. When the cyanide is used in a lumpy state its potency lasts quite long enough to catch those that come in at night.—E. M., *Hants.*

## PUBLIC GARDENS.

### SUMMER FLOWERS IN THE LONDON PARKS.

#### REGENT'S PARK.

REGENT'S PARK is neither a pretty nor happy place for gardening. There is a depressing air about it, a damp heavy aspect, produced by the avenue of large trees that is not wanted where we wish to see the flowers and plants. But in this park we get many beautiful colour pictures, restful and bright, an absence of garish associations and jumbled-up arrangements.

It is pleasant to find that hardy plants are now thought much of in the London parks. Not many years ago scarcely a perennial was visible, nothing but tender bedders, very limited in number, a repetition of a few common things. We saw, however, in this park recently a bank of Hollyhocks in splendid flower, backed with deep green-leaved shrubs and surrounded with Paris Daisies. A bed which we admired greatly was composed almost wholly of succulents, large and small, with here and there the ivory-coloured flowers of the sweet-scented Tobacco (*Nicotiana affinis*) and *Lilium auratum*—a delightful association of glaucous tones. Succulents, when well planted without any straining after impossible effects, are very handsome, and by their distinct, bold and unique character break the tiresome monotony of the ordinary run of summer flowers. A very pleasing bit of planting is that in the form of a rock garden, in which, however, the plants are considered before the stones. There is no backyard rockery about this, but a mass of Saxifrages, Sedums and other creeping things, relieved by the beautiful sprays of the Maiden's Wreath (*Francoa ramosa*). Some of the spikes were the finest we have ever seen, strings, so to say, of pure white blossom. *Araucaria excelsa* was also used to break the surface.

Carnations were going past their best, but sufficient flowers remained to show what pretty masses had been in beauty, the variety *Alice Ayres*, one of the best of all for town gardens, rising from a groundwork of Musk. During the past few years the Fuchsia has become as popular as any plant used in summer gardening in the parks. In this park it is used well and not too freely. A bed of the variety *Earl Beaconsfield*, a very popular kind, and the white Tufted Pansy *Countess of Wharnclyffe* was very pretty; also of the rose-purple *Lady Heytesbury*, planted amongst the old Pansy *Lilacina*. We do not see many mixtures, that is Fuchsias and other plants, or of mixed Carnations. Occasionally such planting turns out well, not often, however, the results being excessively crude and unpleasant. Fortunately, too, there is an absence of so many variegated things as we saw used in every park last summer. An epidemic of pale yellow, creamy white, and other objectionable leafage had set in until the eye wearied of such painful repetition.

We do not care so much as formerly for the scumpleflowers class of Begonias. They are dull looking, especially those with chocolate-col-

oured leaves and dark crimson flowers. A bed, however, of the variety rosea mixed with the free-growing and graceful Grass (*Dactylis glomerata variegata*) was pretty, also one of the dark-coloured kind named rubra with a dwarf yellow-leaved Fuchsia as a groundwork. At the present time one of the great features is the *Celestia*, which creates a gorgeous colour picture of shades of crimson and yellow, especially when mixed with the Cockscomb. They are grown largely, and add splendid colour to the month of August when many things get a little bedraggled. It is grateful to see hardy flowers, a group of Hollyhocks, and in the borders the perennial Sunflower, white Phloxes, Antirrhinums, and many others, whilst crimson and yellow Cannas let into a bay in the masses of shrubs and Bamboos show not only how well such plants thrive in London, but that an earnest attempt is made to get away from beaten tracks and achieve a more natural style of gardening.

#### BATTERSEA PARK.

As usual, the summer flowers here are confined chiefly to what is known as the sub-tropical garden, but in other parts of the park there are some good beds, especially near to the lodge of the superintendent (Mr. Coppin). We were pleased to see good use made of the white-flowered perennial Phlox, which made breaks of purest white. It suggested how fine an effect could be gained by getting a bold bed of it relieved by *Gladiolus brenchleyensis* or a good hybrid kind. A small bed of this *Gladiolus* mixed with *Lilium auratum* is very pretty in the Embankment Gardens at Charing Cross. Several borders at Battersea Park are filled with hardy plants, Phloxes, perennial Sunflowers, early-flowering Chrysanthemums, and with a brilliant and happily arranged broad edging of *Gazania splendens*. This is superb, the large Marigold-like orange flowers standing out against the tufted variegated leafage of grey and white. In another instance the border was planted with standard Fuchsias, Heliotropes, Dahlias, Stocks, and other things—a homely array of well-known flowers. Here, as elsewhere, the Fuchsia is made much of, all the usual varieties being grown in a pleasing way, the arrangement not too huddled up. In one corner we saw a group of Bamboos, which succeed well here, and are quite a relief to the Palms and Ferns placed out for the summer. In the sub-tropical garden proper, *Datura suaveolens*, *Hibiscus syriacus*, and *Eucalyptus globulus* relieve boldly-planted beds of monotony, the silvery leafage of the *Eucalyptus* in particular being in delightful association with the pleasing colour of the Heliotrope. Hollyhocks were at the time of our visit in full bloom, and about this portion of the park splendid specimens of Palms add a touch of tropical aspect to the surroundings.

Single tuberous Begonias are very fine here, particularly one bed, in which the flowers were large, varied in colour, and the plants compact, *Dactylis glomerata* setting off the many charming shades. There is much water in this park, and the margins, fortunately, are not left bare, as in Dulwich Park, where the lake, which is margined with flintstone, makes the growth of pretty water-loving plants impossible. In one portion of the lake at Battersea a mass of the common white Water Lily is protected, and this suggests how delightful would be some of the finer hybrid kinds, which there is no reason to suppose would not do well even near London. They are so handsome and splendid in colour, that we should like to see them tried.

#### MR. A. F. BARRON.

THE council of the Royal Horticultural Society have read with surprise and regret the remarks which have lately appeared in some of the horticultural newspapers with regard to Mr. Barron's retirement. The council have for some time had before them the desirability of making considerable changes in the gardens at Chiswick, and in the early part of this year they determined to initiate these changes in the near future. Fully aware of the value of Mr. Barron's services for upwards of thirty years, recognising that he had well earned and thoroughly deserved a retiring pension, and anxious to show him every consideration, the council felt that at his age they could not fairly place upon him the burden of such a reorganisation as they contemplated, and they considered that they were consulting his best interests, as well as those of the gardens, in offering him retirement on an allowance of £180 a year. In replying to the council's communications, Mr. Barron thanked them for their generous recognition of his claims, accepted their proposal, and tendered his resignation from January 1, 1896. The council are glad to know, and to be able to assure the Fellows of the society, that he is perfectly satisfied. Having acted justly and generously towards Mr. Barron as they believe, and to his satisfaction, the council deemed the matter settled, and were themselves intending to promote a testimonial to him on his retirement, when they found that steps in that direction had already been taken. The council regret to find that they are charged with discourtesy towards the Chiswick Board. The charge rests on their appointment of a special committee to advise them as to the future of the gardens without communication with the board. They freely admit that it would have been advisable to have conferred with the board on the appointment of this committee. To any members of the board who may have felt themselves slighted at their omission to do so, they offer a frank expression of regret. They need scarcely say that the omission was due to an oversight, and not to any intentional discourtesy.—By order of the Council, W. WILKS, Secretary. September 2.

— As one who has had some experience of what has been done at Chiswick in years gone by, I should like to add a few words to the discussion that has lately appeared in the gardening press relative to the retirement of Mr. Barron from the society's gardens. No one who is unacquainted with the various trials of flowers (both indoors and out), fruit and vegetables can have any idea of the labour and worry attached thereto. It is all very well for the committees to go to Chiswick and pass their opinion on this plant and that vegetable, but previous to this having been done, Mr. Barron makes himself thoroughly conversant with every plant, fruit and vegetable sent in for trial, his notes embracing the season through. Take Peas; he used to go through them every day, noting the height, day they came into bloom, when the first pods were ripe for use, and their synonyms. This alone entailed a deal of labour and thought. So with all the trials that were conducted in the garden the greatest care was exercised, and without any favour the value of each and every variety was marked. In one case I well recollect—viz., French Beans—over three weeks was devoted to daily examination of the varieties sent for trial. This was not all, as the dried seed was also carefully examined and classified according to colour, each Bean being divided into two and gummed on to a board covered with white paper, and then covered with glass as in a picture-frame. The collections of Pelargoniums, Phloxes, Pentstemons, Fuchsias, Heliotropes, Neriums, Verbenas, Cannas, Achimenes, &c., were also carefully noted daily. In what private garden can we find the same thing going on? Private gardeners on coming to Chiswick avail themselves of such collections, making their own selections and obtaining plants of the varieties they prefer. In the case of the trial of the Neriums all the known varieties were obtained from Hyères, and if memory

serves me, these had to be bought, all this of course adding to the expense of the garden. I do not believe ever such a collection was brought together, every plant of which flowered and was noted. Again, as regards the shows, where could the R.H.S. find a better organiser than Mr. Barron?

Mr. Barron in a recent article called attention to the meagre amount of money allowed the garden, and the only wonder is how Mr. Barron manages to keep Chiswick in such fine condition on the "starvation" sum. What with wages, coke, manure, soil, in fact everything pertaining to a garden having to be bought, and that at a comparatively high figure, and repairs, the sum is certainly quite inadequate to carry on the place. Certainly much has been done of late in the way of repairs, but much more wants doing. There was, again, the distribution of the plants to Fellows, which entailed a deal of expense in propagating, potting up, attending to and sending out, this last involving an enormous outlay in the way of labour.

For many years Mr. Barron was secretary of the floral committee, but I find that his name has been left out and that of another substituted. As to the reasons which have led to Mr. Barron leaving Chiswick, we are in the dark, so to speak. We should like to see the report (as signed by the committee of experts) published. The gauntlet has been thrown down, and the secretary of the R.H.S., as representing the council, ought to make the Fellows acquainted with the facts of the case, as the business has been carried out in the most un-English way we ever heard of, and the gardeners of the United Kingdom will not rest until the whole matter is fully threshed out and made public.

I am very glad to see that a meeting has been held to further a testimonial to Mr. Barron for his life-long services to horticulture, and may the subscription list be a large one, not only as regards the number of subscribers, but also the sum received.—W. P. THOMSON.

**Report on Chiswick Gardens.**—The following are the names of the gentlemen who were appointed by the council, without the knowledge of the garden committee, to report on the gardens at Chiswick. Those marked with an asterisk are members of the council: \*C. E. Shea (chairman), \*W. Wilks (secretary), H. Selfe-Leonard, \*J. Douglas, \*H. Williams, J. Willard, E. Hill, J. Jaques, and N. A. Barnes.

#### NOTES OF THE WEEK.

**Chrysanthemum Notaire Groz.**—This has probably the most delicate shade of colour among the new earlies, a soft rosy blush. It is a Japanese of medium size and of French origin.

**The yellow Balsam.**—Referring to your note (p. 172) on this plant, I may state that it grows in large masses here, in cool, shady positions in a wood near the hall. I have not, however, seen it anywhere else in the neighbourhood.—J. SIMPSON, Wortley Hall.

**Chrysanthemum President Borel.**—One or two pretty examples of this were shown at the Aquarium show, but it is really an October-flowering variety. The colour is rich rosy purple, with a reverse of mingled gold and silver. It is of Japanese form.

**Chrysanthemum Eugene Farez.**—An early-flowering Japanese, which was conspicuous in Mr. F. Davis's group at the recent Aquarium show. The colour is a rosy crimson, paling a little with age, bright golden reverse, and very useful where colour is required.

**Cyananthus lobatus.**—Among autumn flowers for the rock garden there are few if any more beautiful than this lovely blue-flowered Cyananthus. In a sunny spot it gives a gay succession of bloom during August and September. Its flowers are of a deep purplish blue colour with

white centre. It is now flowering freely with Mr. Barr at Long Ditton.

**Tufted Pansy Charm.**—I should be glad if you will point out to your correspondent "H.," writing on p. 153, Aug. 24, that at the Viola conference, held at Birmingham last year the Tufted Pansy Charm had no special mention.—A. J. ROWBERRY, *President, Viola Conference.*

**Chrysanthemum Harvest Home.**—This is a decided acquisition to the early section. The colour is a bright rich golden yellow, suffused with crimson-orange in the centre. The blooms grow on long stalks, which render them valuable for cutting. It is a medium-sized Japanese.

**Chrysanthemum Mme. Carmiaux.**—A new early variety, a medium-sized Japanese, with drooping florets, which are slightly revolute. In build it is rather a deep flower and of a clear white colour, tinged with yellow in the centre. This variety was commended by the floral committee.

**Budd'ea Lindleyana,** a Chinese species of doubtful hardness, is flowering on a wall in the herbaceous grounds at Kew. The flowers, clustered upon long slender racemes, are small individually, and when first open are of a reddish purple colour, but fade to a much lighter tint with age.

**Tiger Lilies.**—The exceeding beauty of the Tiger Lily as an autumn flower is well seen at Kew, where large beds of it growing up among shrubs are brilliant in colour even from a very long distance. Such effects as this in public gardens should lead others to see the wisdom of growing the good things of each season in bold groups and masses.

**Scabiosa graminifolia.**—The Caucasian Scabiosa in its blue and white forms ranks high among the best plants for the flower border, and its relative here noted deserves an equivalent position among rock garden plants. Its tufts of long grass-like silvery leaves are pretty from spring to winter, and the flowers are produced in succession over a long season. A plant in the Kew rock garden is now in bloom.

**Plumbago Larpentæ** is quite as distinct and handsome with its deep gentian-blue flowers as its lighter tinted relative in greenhouses, but unfortunately it does not flower with the same freedom. It is, however, quite hardy and blooms persistently throughout the autumn months. A spreading mass of it in the rock garden at Chiswick has already commenced blooming, a certain indication of the approaching autumn season.

**Ceanothus Gloire de Versailles** is quite the best Ceanothus for gardens, and in some places may be trusted entirely outside if against a sunny wall. In the R. H. S. Gardens at Chiswick there is a pretty little bed of it, the plants here being treated in a different manner, namely, pruned hard back each year. When planted out in May they start into vigorous growth, and these shoots in autumn are terminated by beautiful panicles of bloom.

**Dendrobium thysiflorum.**—We have received from Mr. Bowring, Beechwood, Aigburth, Liverpool, a photograph of an exceedingly fine specimen of this. The plant carried thirty spikes of bloom, all open at the same time. This resembles *D. densiflorum* in habit, the flowers white with an orange-yellow lip. *D. thysiflorum* when well grown is very telling in a group in the show tent, the drooping racemes having a fine effect along with other Orchids.

**Hardy Cyclamens.**—We were charmed with little colonies of these in the pretty garden at Hurdwicke Grange, near Shrewsbury, when there recently. At Kew also they are flowering freely, and have a pretty effect among the hardy Ferns, which, being thinly planted, appear to furnish just the amount of shade and shelter congenial to them. They are not difficult to deal with if planted under the conditions they like, but as they

are less satisfactory in the conventional mixed beds and borders, they are much more neglected than they should be.

**Chrysanthemum Louise.**—This Japanese incurved variety seems to be one of the most valuable of all the recent introductions. It was shown in excellent form last year at the December show of the N.C.S., and at the Aquarium show on the 3rd, 4th, and 5th inst. it was represented by several good blooms. A variety that can be had in good form, no matter by what method of cultivation, for a period extending over four months is worthy of commendation.

**Coreopsis abyssinica** is a charming annual kind we noted at Kew, robust and bushy in growth, with narrow finely cut leaves and profusely bloomed. Its flowers are individually about an inch in diameter, but the number of them and their rich glowing yellow colour combine to make a bright effect equal to that of any of the larger-flowered sorts. The flowers consist of about eight broad rays, whilst the disc florets are also yellow.

**Colchicums in the Grass** are already flowering freely at Kew, making a pretty picture suggestive of autumn, and one that we should like to see more often. The soft pink flowers are singularly charming growing out of the rich green grass of late summer growth, and nowhere can this be better seen than at the foot of the mound at Kew, where we have often noted charming spring pictures. At the present time the Colchicums are welcome, and well deserve more attention.

**Argemone grandiflora** (the prickly Poppy) is a pretty flower of the present time, and now finely in bloom in Mr. Barr's nursery at Long Ditton. Although at one time thought to be perennial, it usually perishes on most soils during winter, but it is easily raised from seed sown in spring. If the plants are well thinned out they make large branched specimens 2 feet or more in height and diameter, with large white flowers each about 4 inches across, having a pretty tuft of yellow stamens in the centre.

**Lobelia cardinalis Lord Ardilaun.**—I enclose a small piece of a flower-spike of this Lobelia which was raised here by my predecessor, Mr. Campbell. With fair cultivation it grows quite 5 feet high and throws out numerous side shoots. It stood out in the borders last winter with only a slight covering of coal ashes. One night the thermometer fell 3° below zero. A quantity which was taken up, potted and wintered in a cold frame well protected with matting and hay succumbed.—T. SCOTT, *Ashford, Cong.*

**Helenium striatum,** as the name suggests, has striped flowers, but the shades of colour and the irregular manner in which they are blended give a quaint and charming colour-harmony decidedly pleasing. Yellow of an old gold shade and bronzy red are intermingled in an indescribable way, and the effect of the mass of flowers on a plant nearly 5 feet high now flowering at Kew is as good as that of a self-coloured variety. A striking group could be made by planting this in association with the similarly tall and handsome *H. autumnale.*

**Sophora japonica** is now very conspicuous at Kew, two large specimens being literally smothered with flowers, whilst the turf beneath them is white with the fallen bloom. This is a handsome tree in growth and rich foliage alone, whilst the fact of its bursting into bloom when most trees show traces of autumn tints adds greatly to its value for gardens. One rarely sees it, however, except in such places as Kew or in the Oxford Botanic Garden, where the specimen is one of the finest. Every twig of the trees is terminated by a large branched panicle of flowers and buds, that open in succession for several weeks.

**Eulalias.**—These tall and graceful hardy Grasses are now charming at Kew, both in groups associated with the Bamboos and as isolated tufts on Grass in the herbaceous ground. The Eulalia

is much harder than the Pampas Grass, many old-established groups of the latter having suffered greatly from the past winter, whilst groups of the Eulalia in its several forms are growing as vigorously as usual. Although the flowering stage is rarely reached by the Eulalia in our country, and in this respect it falls short of the *Gynerium* somewhat in point of beauty, its tall, erect, cane-like stems are abundantly clothed with the most beautiful leaves. Besides the green-leaved form, the variegated varieties are charming, especially *E. japonica zebрина*, with its transverse bands of yellow. *E. gracillima* is all that the name indicates, and the group of this at Kew is delightful. We note that these Grasses are no longer known at Kew under the name of Eulalia, which has been changed to Miscanthus.

**Actinidia Kolomikta.**—"F. W. M." in THE GARDEN, Aug. 24, p. 138, refers to a plant of *Actinidia Kolomikta* as being "perhaps the finest plant in the country." As a companion to the foregoing plant, I would beg leave to call attention to another specimen growing in the gardens here. Eight years ago I procured a plant of this and planted it as one of a series of climbers, the *Actinidia* in particular being somewhat shaded from the sun. A 12-foot Spruce tree (with the branches shortened in) was sunk in the ground, the *Actinidia* was planted and encouraged to make its way to the top of the tree, which it did in about four years. It is now not a stiff and formal plant on a wall, but a handsome tree, 12 feet in height by 6 feet through, and beautifully furnished all round. The beauty of the plant is still further enhanced and also its vigorous growth proved by the rapidity with which the summer shoots run out and form festoons in all directions. I have never yet seen a flower. As to its thorough hardness, there can be no question, for the severe frost of last winter never injured it in the least.—M. CHAPMAN, *Easter Duddingstone Lodge, near Edinburgh.*

**The weather in West Herts.**—A very hot week, the highest shade temperature on one day reaching 76°. The ground has also been unusually warm for the time of year. In fact the reading at 1 foot deep is now about 5° higher than the average temperature at this depth for the early part of September. No rain worth mentioning has fallen for over a week, and the drainage through the percolation gauges has almost ceased. During the past seven days the record of bright sunshine has been remarkably good, the duration amounting on an average to very nearly 10 hours a day. August was a warm summer month, particularly the latter half of it. Rain fell on as many as nineteen days, and to the aggregate depth of nearly 4 inches, or 1½ inches in excess of the August mean for the previous forty years. The three summer months taken together were warm, and the rainfall in excess of the average. Although July and August proved unusually wet, the total fall of rain since the beginning of the year is rather more than 2 inches less than the mean.—E. M., *Berkhamsted.*

**Gustav Sennholz.**—In our obituary notice of this landscape gardener in the last issue the name should have been spelled as above, and not as in the note.

**Names of plants.**—S. N. T.—1, send again; 2, *Ephedra* sp.; 3, *Dictamnus*; 4, *Gilia*; 5, Evening Primrose (*Oenothera Lamarckiana*); 6, not recognised. We have done the best we could, but the specimens were far too poor to be quite certain as to names.—H. J. D. Walker.—Rose Ophiric.—*Anon.*—*Oncidium curtum.*—*Old Windsor.*—*Bignonia radicans grandiflora.*—A. Maxwell.—1, *Cornus sanguinea variegata*; 2, *Cornus mas elegantissima*; 3, *Cornus mas* var.; 4, *Cornus brachypoda*; 5, *Abies pungenis glauca.*—Alpha.—1, *Acer dasycarpum*; 2, *Euonymus europæus*; 3, *Syringa Emodi*; 4, *Betula populifolia*; 5, *Ilex domingtonensis*; 6, send better specimen.—A. M. Z.—*Lomaria alpina.*

**Names of fruit.**—James Day.—Plums, 1, *Oullin's Golden*; 2, *Jefferson*.—J. C. Sheppard.—1, *York-hire Beauty*; 2, *Gravenstein.*

"This is an Art  
Which does mend Nature: change it rather; but  
THE ART ITSELF IS NATURE."—*Shakespeare*.

## ORCHARD AND FRUIT GARDEN.

### SEASONABLE NOTES ON THE FRUIT GARDEN.

At the present date, September 6, the drought appears to be more seriously affecting fruit trees than it has done before this year. Many Apple and Pear trees that have not been mulched or thoroughly watered are casting their fruit in an alarming manner, and if we are fortunate enough to get rain, I question if it will be of much benefit except to the late sorts. The probability is that most of the early and mid-season varieties would decay rapidly from the sudden rush of sap after a copious rain. It has been pointed out in *THE GARDEN* on several occasions that our rainfall is considerably below the average for several years past, and attention has also been drawn to the dry condition of the roots of wall trees in consequence of this deficit. I think it may be advisable to again recommend giving all wall trees a thorough soaking of water now, thereby assisting them to perfect their buds and wood for next season, and keep red spider from completely spoiling this year's growths. Damsons in the open orchards are more violently attacked by this mite than I ever saw them before, and wall trees come next, followed by Gooseberry bushes. Apple trees are infested in a less degree, but some varieties of these are worse than others. As red spider will exist on the trees or bushes through the most severe winter, increasing and multiplying rapidly with the advent of warmer weather, it stands to reason that if all or a part can be destroyed this autumn, the attack will be minimised next spring. It is marvellous how much may be done to keep insect foes down by timely attention to the pests at this season, and, judging from my experience, I believe that autumn washing or spraying of fruit trees is more important and valuable than the same performed in early spring. As a case bearing on this matter, I may state that we have a plantation of Plums that some years ago was always subject to aphid and red spider attacks in spite of early washings with well-known insecticides. Immediately after the pruning was done three years ago the trees were thoroughly sprayed with the usual insecticide, and the result has been that no red spider and practically no aphid have appeared since, proving that the annual autumn washing is effective. Again, if Plum trees have to be sprayed in the summer when the fruit is more or less advanced, the bloom on the fruit is ruined. The Plums never look so attractive, no matter how large they may grow. Black Diamond is perhaps one of the worst Plums to show the effects of summer spraying, every spot of insecticide that falls on the fruit being very conspicuous when ripe. In those gardens where the labour is available it will be best to prune Plums, Peaches, Nectarines, Cherries, &c., at once, and then wash them afterwards, as the work can be performed more effectively and expeditiously with less waste of liquid than in the case of unpruned trees. It is not every gardener who can afford the time and labour to thus have the trees pruned and put in proper order, but when it is possible I strongly advocate pruning as early as convenient after the

fruit is all picked; by doing so the wood and buds become hardened and well matured, calculated to pass through the most severe weather uninjured, and will start again in spring strong and healthy. A very large proportion of fruit trees is in a more or less exhausted state from the heavy crops they have carried this season, but in spite of these big crops I never saw trees of all kinds show more fruit-buds than they do now. Will this splendid promise be fulfilled next year? I think not, because so few supply sufficient plant food to enable the trees to bear good crops two years running. Opinions differ as to the best time to apply fertilisers to fruit trees, and no doubt soil and subsoil must have an influence on the same, yet I believe that an early autumn dressing of natural or chemical manures very materially strengthens and invigorates exhausted trees. On our light soil kainit proves a most serviceable manure for application in September. From three to five cwt. per acre is a fair dressing, and no anxiety need be felt as to its promoting a rank growth when the trees start again. The tendency is rather to induce a fruitful habit than a gross one. Liquid manure, sewage, road scrapings, decayed vegetable matter, ashes from the garden rubbish heap, or anything of that kind may with advantage be given to trees in the fruit garden or orchard. W. G. C.

**Cardiff Castle Cucumber.**—For many years I have grown Telegraph Cucumber, considering it one of the best all-round varieties, but this year I have grown Cardiff Castle with it under exactly similar conditions, and found the latter far more prolific and bearing finer fruit for a longer period than Telegraph. Possibly some would remark that the season has been perhaps more suitable for Cardiff Castle than for Telegraph, but I think seasons have little influence on varieties of Cucumbers grown under the non-ventilating system and given the same compost and general treatment. When at the recent Cardiff Horticultural Show I asked Mr. Case (the largest Cucumber grower in Wales) what he thought of Cardiff Castle as a market variety. The answer was a very decided one in favour of the sort named, he also saying that no other variety could equal it for the purpose, which means a good deal when it is borne in mind that hundreds of dozens are sold per week by Mr. Case.—G. C. R.

**Golden Perfection Melon.**—This really first-class Melon is now seldom met with, which is rather difficult to account for considering how handsome in form and colour and delicious in flavour the variety is. I have grown this sort for a number of years in pits and heated frames with excellent results not only for my employer's table, but also for exhibition, on many occasions taking premier honours with it, for when well ripened there are few Melons to surpass it. Another great advantage is the healthy habit of the plants, canker never putting in an appearance on our light soil, while the fruit sets and swells remarkably well. Several gardeners who have seen it here have been astonished at the number of fruits per plant, saying they always thought the variety a shy setter. Such has never been my experience, and to those who require a pale fleshed Melon of high quality and free habit I can confidently recommend Golden Perfection.—G. C. R.

**Apple Magnum Bonum.**—This is an early variety that should not be confounded with that excellent dessert Apple Roundway Magnum Bonum, as the one under notice is a cooking Apple, somewhat resembling the old Keswick Codlin in colour, but entirely free from ribs: the surface is very smooth, straw coloured and dotted all over with tiny dark spots—in fact, it is a very attractive variety and a heavy cropper, so much so that the trees make scarcely any growth. To see the trees loaded with good-sized fruit of beautiful form many would imagine that it was

eminently suited to grow for market, but though a most excellent Apple for home use, it is too soft and tender to ever become a favourite market sort.—W. G. C.

**Apple Crimson Costard.**—This Apple will, I believe, come to the fore ere long as an exhibition variety, as it combines size and colour, and is distinct from any other sort that I know. The first time I saw it I was judging with Mr. Petch at Manchester, and we both were struck with the beauty and size of the dish which formed a feature in the back row of Mr. J. Watkins's collection. I procured some bush trees two years ago, and this year they are bearing some fine fruit. Two of the best Apples were spoiled; one weighed 17½ ozs., and the other turned the scales at 16 ozs., and would probably have been still heavier if uninjured. The fruit is conical in shape, nearly as red as Worcester Pearmain on the sunny side, and, judging from present appearances, the tree is going to be a profuse bearer in bush form.—W. G. C.

**Currant Houghton Castle.**—This is a valuable Red Currant. I grow no other variety, except upon a north wall where I grow the Red Dutch. Bushes of Houghton Castle in the open are generally covered with plump fruit the first week in October. All through the month of September it is found most useful when other small fruit in the garden is scarce. Much the best way to grow the trees of this variety is to train them at first with a limited number, say nine to fifteen main branches and a clean stem. From these branches the fruit is produced right down to the bottom of the trees, is always clean and good in colour and size. Besides, the gathering of the fruit is so much facilitated by the absence of so many small branches as one too often finds in bushes of Red and White Currants. By going over the trees once about the middle of June, lopping off the current season's shoots to within 4 inches of their base, not only is the fruit improved in its ripening, but it is kept quite clean by being exposed to rain and heavy dews, which effectually keep it clear of honeydew, which is so troublesome to Currants in some seasons.—E. M.

### NOTES ON APRICOTS.

I OBSERVE several correspondents of late have complained of the behaviour of Apricots. During the last three years I have been most successful with them. The fruit has set so freely, that two out of three had to be taken off in their early stages. So abundant was the set, that I counted from twenty to thirty fruits on a shoot a foot long. The situation is not favourable to Apricots, seeing we are in a low valley and close to the water; consequently the trees suffer from spring frosts and also unripened wood. The trees are protected by a glass coping 2 feet wide; in front of this I hang curtains when the blooms are opening, removing them by day. Some cultivators object to fixed coping, but nothing could be more satisfactory with me. The border is a raised one with a sharp pitch, consequently it dries quickly. Some two years ago I removed most of the soil to the depth of 2½ feet, adding some chalk to the under spit and replanting the trees. This keeps the border very dry and causes the wood to ripen well. The greatest difficulty I have to contend with is to keep the border moist in dry weather, as the vegetables and tree roots absorb such a quantity of moisture. Having a good supply of water, I allow a hose to run a long time in each place. When the early Potatoes and Peas are cleared off and the fruit begins to swell the second time, I give the border a good dressing of an artificial manure, well watering it in and again in a fortnight. This works a great change in the fruit and colour of leaves.

From a wall space about 60 feet long and 12 feet high, two seasons following I gathered nearly 150 dozen, and this season close on 100 dozen. The cause of the smaller crop this year arose from the trees having but few fruits on the three lower

feet of wall, as the frost destroyed the blooms in winter on this space; nearer the top the blooms did not suffer in the least. This I attribute to the coping favouring the wood and bloom.

Some people are apt to think Apricots have a short season; this is not so, seeing most years I have them for three months. I begin with the Large Early, and find Powell's Late continues to give a supply till the end of the twelve weeks. Moorpark and its varieties are much the largest and best, but the trees are apt to die off, although I cannot complain in this way. It is now September, and I have enough to keep up the supply another fortnight.

JOHN CROOK.

**Currants at exhibitions.**—At our show we allow exhibitors to stage Black Currants in single berries. By specifying in the schedule to this effect, all are placed on an equality. We do not, however, allow the same thing to be done with either red or white kinds, these being shown in bunches.—E. M.

**Plum Angelina Burdett.**—This is the best dessert purple-coloured Plum for those who cannot give it wall space that can be grown. The tree grows and bears freely either as a standard or spreading bush. When grown in the form of a pyramid it does not bear so freely, the severe pruning to bring it into form not suiting it. Another point of merit is that the fruit does not set in bunches: it is more evenly distributed along the branches, and therefore develops to a good size with very little thinning out. When the fruit is thoroughly ripe the flavour is excellent and the form is handsome as well; it also carries a good bloom, and is therefore effective on the dessert table. Of course, the tree may be trained against a wall where room can be given it, but then the richly flavoured Plums that can be ripened without the assistance of a wall are so few that the merits of Angelina Burdett in this respect cannot be too well known.—J. C. C.

**Cox's Orange Pippin Apple.**—It is surprising to learn that this delicious Apple will not succeed at Claremont, especially since King of the Pippins does well there. Perhaps the method of treatment or of pruning given there may differ from what is given elsewhere, but I have seen the variety doing well on sandy soil in other parts of Surrey, grown somewhat freely and only thinned, but in no respect spurred or shortened back. This Apple has been cropping wonderfully on dwarf standard or half-bush trees at Chiswick. These same trees not only fruited well last year, but do so usually. They are in no sense hard pruned, but, in common with all Apples at Chiswick, are well thinned. There the trees generally assume a drooping habit, and no doubt that very habit is most conducive to cropping. I saw Cox's Orange Pippin on standard trees at Sulhampstead, Berks, the other day, the soil being shallow on gravel, and yet in a grass orchard bearing splendidly and the fruit colouring up beautifully. In Middlesex I have seen the Apple doing wonderfully well on stiff clay, and again on gravel, and in districts in Surrey it does well on chalk. Generally it is best on the free stock, as it is never a coarse grower, and once it begins to fruit, the drooping habit in the branches is created, and afterwards maintained.—A. D.

#### THE APPLE CROP.

From all parts of the kingdom the same report comes to hand, viz., an abundant crop of Apples, and those who are directly interested in their culture, and especially those who contemplate planting during the coming season, should now take note as to which varieties are the most profitable, and, above all, which varieties succeed best in their own immediate neighbourhood. From my own observations I am convinced that too many of the very early Apples of the Codlin type, such as Lord Suffield, have been planted during the past twenty years, and as they all come into use about the same time as the Keswick Codlin, and

must be sold or used within a very limited time, the result is that prices go down to a very low figure indeed. I never remember observing so many Apples affected with maggot. Probably some correspondents in other parts of the kingdom may be able to inform us if this pest is general, and what steps we can take to prevent its recurrence. Many people gather sorts that would be all the better for banging much longer on the trees, and by forcing them on the market at a time when it is already overdone, the price is forced down below what it would otherwise be. It is of no use looking to townspeople to store fruit, for they have no space at disposal for the purpose, a veritable hand-to-mouth existence, and the storing, if it is done at all, must be done where the fruit is grown. Fruit farms are springing up in all directions. It is not enough to simply plant the trees and let the crop be carted straight from the trees to the nearest railway station or market, for this is only playing into the hand of the importers, as our home crop is gone as soon as it is a heavy one as if it is a light one, and the markets and high prices are left for foreigners to get the benefit. What is wanted is really good store houses that will defy heat or cold and on the ground floor and partially below the ground level. I have lately found such a place invaluable for retarding the too rapid ripening and shrivelling of the early sorts, for even a few days' retarding frequently means all the difference between a small profit or an actual loss. That we can grow the best Apples in the world has been proved over and over again, and with land almost going begging we ought to be able to grow enough Apples. To do this we must not only plant really late keeping sorts, but they must be stored in such a way as to ensure their keeping until the maximum price can be obtained in the market.

Gosport.

JAMES GROOM.

#### SCALE ON VINES.

My early Vines, now just finished, have been affected all the season as per accompanying leaves. The berries were good and of good flavour, but the top of the bunch looked as if mildewed. We have had a great deal of rain and the house is not water-tight. Is this the cause or what?—NEWCASTLE.

\*\*\* At first sight the leaves presented the appearance of being badly mildewed, but on a closer examination I arrived at the conclusion that the whole of the trouble had been caused by brown scale. The leaves sent were thickly coated by the at one time sticky excretions from the scale, some of which were still clinging to the foot-stalks. Although in a wretched plight, the remedy is far simpler than would have been the case if mildew had been responsible for the mischief. Syringing with hot water and petroleum, using the latter at the rate of 1 wineglassful to 2 ounces of petroleum, and a lump of soft soap about the size of a hen's egg to the gallon of water heated to a temperature of 120°, quickly clears a Peach tree of this pest if applied any time after the leaves are fallen. In the case of the Grape Vine, petroleum in any form is somewhat risky, as it is liable to penetrate through the porous bark to the sap vessels and cripple, if not actually destroy, the rods. Much good would be done by at once sponging the larger or primary leaves with hot soapy water so as to get rid of the coating of filth that hinders them from performing their proper functions, but the cleansing process must be largely deferred till the winter. After the pruning has been done, bunch the rods together and enclose with mats, thick canvas and such like, then give the old scale-infested roof a thorough cleansing with the petroleum, soft soap and hot water mixture previously alluded to. The petroleum should be kept from collecting on the top and being used at too great a strength by means of the syringe driving it downwards. Also wash the glass and dress all the brickwork with hot limewash. The rods may then be uncovered, roughly cleared of loose bark, and receive at least two good scrubbing with hot soapy water.

Afterwards dress with Gishurst compound, dissolved and diluted according to instructions on each box (any seedsman would supply it), and well mixed with clayey water. Brush this well into every probable lurking-place of scale. Some few may escape the most drastic measures of cleansing, and a close look-out should be kept during the growing season for any that find their way to the leaf-stalks. If there is an inside border, remove the surface-soil after the other work has been done and top dress with a rich loamy compost.—W. I.

#### GOOD RASPBERRIES.

I TRUST Mr. Engleheart, "D. T. F." and Mr. Bedford will pardon me not replying earlier to their courteous criticisms with regard to my note on the above. The delay has caused me to make inquiries as to the value of Superlative in various parts of the country, these confirming my previous notes and giving me much stronger facts than I could have otherwise produced. I am obliged to differ from Mr. Engleheart as to his opinion of Superlative, and I do not retract one word of my previous note as to its excellence, either as regards crop or flavour, on a poor, thin gravelly soil where other varieties have failed. If Mr. Engleheart and "D. T. F." will carefully read my first note (p. 40) they will find I did not refer to flavour, recommending Superlative for its cropping qualities and its value on a poor soil. I admit Baumforth's Seedling is an excellent earlier Raspberry, but not equal in a poor soil to Superlative. Mr. Engleheart takes Red Antwerp as his standard. I grew this variety years ago, and if my memory serves me right, it was remarkable for its sweetness. I never detected the least acidity in this old variety. I have this day (September 9) gathered fine fruits of Superlative, and though the canes have been bearing nearly two months, there was still the brisk flavour I alluded to. I also grew another variety, probably Semper Fidelis, the fruit of this being decidedly acid. Red Antwerp was grown for its sweetness and Semper Fidelis for cooking. On the other hand, do not seasons and soils affect the quality of fruit? At p. 147 Mr. Bedford says "he has no need to water, the drought having been a blessing." I had to water freely and mulch heavily. It was as a good dry weather fruit I advised Superlative. Again, Mr. Engleheart says his is a good soil; mine is the reverse. Baumforth's lives with me, but does not thrive. I am required to produce fruits in quantity, and Superlative up to this date has produced three times the quantity of other kinds. As to its value in a preserved state I have strong testimony. I will briefly answer "D. T. F." In my experience Superlative crops longer and heavier than Baumforth's. The last three seasons I have seen it fruit well into October. The reports from the largest growers are that Superlative is the best cropper and well flavoured. Another sure test is the demand for canes, the demand being so great it cannot be met. I have noticed some large quarters planted recently by well-known growers, and in the back numbers of THE GARDEN there are many references to Superlative and its good flavour. My opinion is that Superlative, though later than many others, is more prolific and not inferior in flavour.

G. WYTHES.

**Gathering fruit.**—The note at p. 173 by "H. C. P." is most opportune, as at this date many will be thinking of gathering the earliest Apples and Pears. The season named for the storing of such kinds as Northern Greening and the others mentioned may by some be thought much too late, but such is not the case if the fruits are required to keep well into the spring; indeed I could largely supplement the list, but will briefly add that such kinds as Cox's Orange, Fearn's Pippin, and similar dessert kinds are much improved by free exposure till the latest date possible, as these fruits so soon shrivel in a close room, that when gathered early they are almost valueless by Christmas. The well-known useful

CHRYSANTHEMUMS.

CHRYSANTHEMUMS IN RUSSIA.

THE article under the above heading in THE GARDEN (p. 133) is very interesting, and shows that if R. Katzer is a beginner in the culture of the Chrysanthemum, he has at least a knowledge of the different systems and much success, which prove that there is also a great love for the work. One of the surest signs of the hold the autumn flower has upon all is the fact that its cultivation is rapidly extending in other countries besides our own.

The chief desire of your correspondent appears to be to grow what are called fine blooms, but without having the plants run up to an ungainly height. R. Katzer's knowledge of the modes of "cutting down" is particularly full, and it is therefore unnecessary to dwell upon the point, only to emphasise the remark that it does not seem possible to obtain the largest flowers from any system except allowing each sort to assume its natural height. It is in regard to a selection of varieties that I offer to venture some advice. The greater number of the best varieties of quite recent years have a decidedly improved habit of growth. It is now possible to cultivate most excellent sorts that do not reach a height of above 4 feet, grown as in Russia from what would be with us late-struck cuttings and allowing a good space between each plant. This last is an important item; crowding has much to do with the excessive height of Chrysanthemums. A list of varieties will be added at the end of these notes.

Regarding the failure of *Avalanche* to produce perfect blossoms, this fine white variety is not so constant as formerly—whether through excessive propagation or over-cultivation, it may be both, I cannot say, but instances are plentiful of once handsome varieties becoming difficult of culture. Take *Mme. Clemence Audiguier*. Its ungainly height had something to do with many discarding it, yet many others failed to obtain that perfect lovely incurved form and taking shade of mauve colour which made it so popular for a few years. *Belle Paule*, *Triomphe de la Rue des Châlets*, *Thunberg* are also examples, and I am inclined to think the beautiful *Vivian Morel* and its sport, *Charles Davis*, will degenerate through their habit of forming premature flower-buds. I think the recently introduced *Souvenir de Petite Amie* a decided improvement. It is among the dwarfest of Chrysanthemums, and the pure white blooms are particularly handsome. Such whites as *Mlle. Thérèse Rey* and *Niveum* should be grown in the place of *Puritan* and *Bouquet de Dame*.

Your correspondent asks for a variety to replace *Edouard Audiguier*. *Commandant Blusset* has a very similar lively shade of carmine colour and long drooping petals; it is not so likely to suffer through "damp" as is the older, uncertain kind, and the habit of growth is much dwarfed. It is somewhat early, being at its best towards the end of October. The cause of the variety *William Seward* twisting its petals and thus exhibiting too much of the reverse shade of colour is through early bud-selection. I would suggest to R. Katzer that the buds of this strikingly handsome sort be taken later than has been usual. It is to my thinking by far the best very dark Chrysanthemum yet obtained.

The remarks upon the want of artistic training noticed with our prize-winning standard Chrysanthemum plants may well receive the attention of those who have the management of our exhibitions. It is a matter of wording in schedules. In private gardens one sometimes

meets with informally trained heads upon clear stems, and handsome specimens they are, but in most cases at the shows close tying is too much *en evidence*. In the list given below the varieties are nearly all of the Japanese type. This class has been improved so rapidly, that gains in other types seem rare. It would, again, be unnecessary to include incurved sorts, dwarf-growing ones being almost unknown, and in considering the height, I have borne in mind the system of late striking adopted by your correspondent.

CHRYSANTHEMUMS FOR SEPTEMBER.

*Mme. C. Desgrange*, white, 2 feet; *G. Wermig*, yellow, 2 feet; *Lady Fitzwygram*, white, 2 feet; and *M. G. Grunerwald*, lilac, 18 inches.

VARIETIES AT THEIR BEST DURING OCTOBER.

*Commandant Blusset*, carmine, 3 feet; *E. Molyneux*, crimson and gold, 3 feet; *Gaspard Boucharlat*, orange-bronze, good standard; *G. C. Schwabe*, carmine-rose, 3 feet; *Louise*, blush white, 30 inches; *Mlle. Lacroix*, white, 4 feet; *Mlle. Thérèse Rey*, white, 4 feet; *Mrs. E. S. Trafford*, bronze-rose, 3 feet; *President Borel*, bright rose-purple, 4 feet; *Ryecroft Glory*, buff-yellow, good standard; *Souvenir de Petite Amie*, white, 30 inches; *William Tricker*, soft rose, 3 feet; and *W. H. Lincoln*, yellow, 3 feet.

FIRST-CLASS SORTS FOR NOVEMBER.

*Anna Hartshorn*, white, 4 feet, uncertain; *Charles Davis*, bronzy buff, 3 feet; *Col. W. B. Smith*, bronzy yellow, 4 feet; *Duchess of York*, yellow, 4 feet; *Eda Prass*, blush-pink, 3 feet; *Florence Davis*, white tinged green, 4 feet; *Hamlet*, cerise salmon, good standard; *John Shrimp*, ton, crimson, 3 feet; *Mme. Carnot*, white, 4 feet; *Mme. Ad. Chatin*, white, incurved florets, 3 feet; *Mlle. Marie Hoste*, creamy white, 4 feet; *M. Ch. Molin*, bronze, 3 feet; *M. Gruyer*, pale rose, 4 feet; *M. Pankoucke*, yellow, 3 feet; *Niveum*, white, 4 feet, good for standard; *Sunflower*, yellow, 4 feet; *Vivian Morel*; and *Viscountess Hambleton*, blush-pink, 4 feet, uncertain.

H. SHOESMITH.

NEW HAIRY CHRYSANTHEMUMS FOR 1895.

It seems scarcely possible to say much respecting this new section of Chrysanthemums, and the novelties for the present year call for very little comment. The interest in the race was first aroused by the advent of *Mrs. Alpheus Hardy* and sustained by the introduction of several other forms, but, taken as a whole, hairy varieties of the popular autumn flower must be regarded as a somewhat disappointing class. Prizes for them are offered in the N.C.S. schedule, and may be the means of bringing forward some good examples of horticultural skill at the next November show at the Aquarium; but to my taste the white varieties are the most useful, especially when grown freely for cut flowers. In this way medium-sized blooms, with their peculiar fluffy appearance, may be used with effect in bouquets or in vases with other subjects, but the varieties of purple or bronze shades are far from pleasing, as the tone of colour is often dirty or uncertain.

Having for several years placed on record the names of the novelties as they have come out, it seems to be useful to record those for the present year, but it will be seen they are far less numerous, and no doubt the little encouragement given of late is the cause of the number being so small. As florists' flowers, hairy Chrysanthemums are as yet a failure, and can only be regarded as mere curiosities.

*Albinos (Crozy)*.—Pure white.  
*Dragon (Lacroix)*.—Broad petals, violet-brown-red, reverse old gold.  
*Mme. M. Marchand (Marchand)*.—Incurved; bright rose, tinted salmon in centre.  
*M. François Alotte (Reydellet)*.—Japanese; dark garnet-red and ochre yellow.

*Cellini Pippin* is one of the worst keepers if gathered too early, as the fruits sweat so badly. Though this is considered an early autumn variety it is much better when allowed to hang till the latter part of September. I am aware there is a certain amount of loss by dropping, and of course seasons must be considered, but I do not hesitate to say there is much greater loss when the fruit is stored too early, as a large portion decays and the other is so shrivelled that it is worthless. Some of the small late dessert fruits have a greater tendency to shrivel than others. This can be prevented by late storage. It is surprising how long a *Cox's Orange* will keep good if gathered late, and how much the flavour is improved by hanging. Again, the way the fruit is stored is another point worth more attention. Many varieties would be more valuable if gathered later and given a rough store. Those with ample floor space could often utilise spare cool places in preference to heated fruit rooms. Much may be done by going over the trees occasionally, gathering the ripest and not taking the whole crop all at once.—G. WYTHES.

**The Japanese Wineberry.**—My recent experience of this has modified my opinion of its merits. I now think that in the near future it will be generally cultivated as a profitable fruit. Some seedlings planted out in deep rich soil last year made rods 10 feet long, which were uninjured by the severe winter. These are now loaded with large sprays of fine, glossy red fruits, which when ripened in the sun are very pleasant, but on the shady side are somewhat tart, and they come in when all other bu-h fruits are over. A further recommendation is that birds appear to care nothing for them, which seems unaccountable; even those ravenous, all-devouring pests—black-birds, that attack every fruit, leave them alone, while a heavy crop on a large specimen of *Elaeagnus edulis* a few weeks ago was all cleared off by them before they were ripe, and the North American Wineberry was similarly stripped. Those having a suitable soil—I mean a deep rich one—would find a small plantation of it very useful, but it is not of much account in poor or shallow ground, the growth is weak and the fruits small and few. I have another species which I received from New York, called the Golden Japanese Mayberry, which appears quite distinct, with yellow fruit and neat foliage. It has not yet fruited with me—J. M., *Charmouth, Dorset*.

SHORT NOTES.—FRUIT.

**Apple Red Aetrachan.**—Although not of high flavour, this Apple deserves to be more grown than it is at present. The tree as a bush does not require a large amount of space, it crops well, and for colour the fruit cannot be surpassed. As a market Apple it cannot fail to be a success, as its rich colour is sure to sell it.—E. M.

**Apple Duchess of Oldenburg.**—At one time I thought this Apple was going to be a failure in our heavy soil, as every tree exhibited signs of canker. By raising the roots near to the surface this has been got rid of. For market I regard this as an excellent Apple; its bright and attractive appearance cannot fail to sell it. For cooking it is quite in the front rank amongst early Apples.—E. M.

**Apple Benoni.**—I look most favourably upon this Apple for dessert. It is not often met with in private gardens. In appearance it much resembles *King of the Pippins*, except that it is not quite so high, being rather flatter. The fruit ripens about the middle of September, just at a time when dessert Apples are scarce. The tree is compact in its growth, requiring but little space to grow in, as its natural tendency is an upward one.—M.

**Plum Diamond.**—At p. 145 "J. C." Newark, refers to the above, but makes a slight error in the spelling. I saw this variety in fine condition at the Edinburgh Plum congress in 1889. It is a splendid cooking Plum, and makes a good standard, but with me requires much thinning of the branches to be fruitful. I have seen it recommended for dessert when allowed to hang, but I do not advise it for that purpose. I quite agree with "J. C.'s" note as to its preserving qualities, and, given good culture, it attains a large size.—S. M.

*M. Joseph Allemand* (Colvat).—Japanese incurved; dark lilac-rose.

*Mrs. Higinbotham* (Spaulding).—Japanese incurved; broad spreading bloom, bright pink; said to be one of the largest.

*Mrs. W. J. Godfrey* (Godfrey).—Broad incurved flowers, colour white.

*Oruba*.—Clear light pink, slightly covered with hairs.

*Perle d'Or* (Boucharlat).—Incurved; Narcissus-yellow, reverse silver.

*Triomphe* (Crozy).—Long petals, salmon-rose, passing to pure salmon. C. HARMAN-PAYNE.

## NOTES OF THE WEEK.

**Physalis Franchetti.**—This large edition of *P. Alkekengi* (the Winter Cherry), introduced by Messrs. J. Veitch and Sons, decidedly merits all that has been said in its favour. It appears to be earlier than its older ally, and the orange calyx which encloses the fruit is nearly twice as large as that of *P. Alkekengi*. The plant is much stronger and sturdier in every way. In the Cambridge Botanic Garden some of the calyces have already coloured, while those of *P. Alkekengi* are still quite green. It will prove exceedingly valuable for decoration. It is a native of Japan.—L.

**Hibiscus syriacus.**—I notice that your correspondent "E. M.," in alluding to this plant, mentions that it does not succeed on soil at all mixed with chalk. I happened, however, the other day to see two beautiful plants in a small plot only a few yards square in front of a cottage at Lewes, each of which was flowering most luxuriantly and formed a very striking picture. One was of a pale lilac colour and the other a pure white with a claret spot in the centre of each petal, and these were growing in a chalky soil. The whole subsoil of the district was chalk.—JOSEPH CHEAL.

**Hunnemannia fumaricæfolia.**—This showy Mexican plant is now flowering profusely in the rock garden at Kew. The plant is about 2 feet high, the general habit of growth erect, the growth terminated by large, solitary, cup-shaped blossoms of a rich clear yellow. At first sight the flowers have somewhat the appearance of those of *Eischscholtzia californica*, though not so widely expanded when fully open. The plant is worthy of general cultivation, and by its distinct foliage and glistening yellow blossoms would make a showy bed for a long season. Plants are easily raised from seeds, which should be sown either late in autumn or quite early in the year. Liberal treatment is essential from the beginning.

**Linanthemum indicum.**—In the Cambridge Botanic Gardens this is the most charming of recent additions to the collection of water plants. It is cultivated in the tropical aquarium, and there produces numerous floating leaves, bright green, nearly round, and resembling those of our British *L. nymphaoides*, but without the dark blotches. The flowers are white and the corollas, in which all the beauty lies, are exquisitely fringed and covered all over with white hairs. They are each about an inch across, and produced in clusters on what appears to be the petiole, a little below the leaf blade. For a small aquarium nothing is more charming than this. It is a native of the East Indies, though received from one of the nurserymen in the United States.—L.

**Roses at Kew.**—Roses contribute much to the present abundance of flowers to be seen at Kew, and we noticed that visitors appreciate them greatly. Two beds filled with Teas in two kinds, namely, Marie van Houtte and Comtesse Riza du Parc, were perfect pictures of colour when we saw them, and it would be wise to extend the Rose plantations on the same lines, planting only first-rate kinds. Another bed of Grace Darling shows this Rose as handsome and free as we ever see it, the strong summer shoots now crowned with great heads of fine blooms. Camoens also makes a gay bed, whilst among Monthlies, Mme. Laurette Messimy is specially charming. The good old Fellenberg fills a large bed and seems proof against mildew, which disfigures somewhat

the two sorts previously mentioned, whilst as a Rose for grouping to make a gay display of colour, none surpass, and indeed very few equal, Fellenberg. A few H.P.'s are also flowering freely.

**Rudbeckia speciosa.**—Never have I seen this Coneflower flowering so profusely as at the present time. It is undoubtedly one of the finest of hardy border plants we have under certain conditions. Being a surface-rooting plant it quickly suffers from the want of moisture during a spell of dry weather if the situation is a dry one. In that case water must be freely given to obtain anything like a representative growth and afterwards a full crop of flower. By supplying moisture when required, my clumps of this plant are fully a yard across, the individual flower-stems 2 feet high. Planted alternately with *Aster Amellus bessarabicus*, the rich orange-yellow of the *Rudbeckia* contrasts favourably with the purple of the *Aster*.—E.

**Apple Blenheim Orange.**—With me for the first time in sixteen years the trees of this Apple are carrying a full crop. It has truly been a struggle on their part during that time to make headway against canker. By lifting them entirely and freely supplying them with liquid food the trees have made very good progress during the last five years, and are now almost free from canker. In our soil the trees grow fast enough during the summer, but by the spring-time nearly all of the growth made previously is killed by frost owing to its unripe condition. No Apple seems better fitted for growing as a standard than the Blenheim Orange. In spite of the difficulty of establishing the trees I should advise those making a new orchard to plant one or two of this Apple, keeping the roots on the surface when planting, and mounding them over with light soil with which wood ashes has been freely mixed.—M.

**Martagon Lilies.**—Occasionally one sees fine examples of plants in out-of-the-way gardens and places where little or no attention is given, and where the plants grow and flourish year by year uncared for and undisturbed. I came across some large clumps of *Martagon* Lilies quite recently in the hill district of Gloucestershire. The plants were evidently at home, as may be gathered from the dozen or more stout stems of which the clumps were composed. Of course, the plants had finished flowering, but the stems were there quite 5 feet high, and the petioles and seed-pods in numbers. Some of the stems had carried nearly fifty flowers, and, singularly enough, one of the largest clumps occupied a position in a narrow border at the southern end of a large outbuilding. Notwithstanding the great heat to which this particular clump must have been exposed during the season the foliage was quite fresh and good. This I believe in a great measure to be due to the roots being in contact with the rocks below, which in the district referred to are quite near the surface. The soil is a light fibrous loam, freely intermingled with small stones of the magnesium limestone of the district.—J. M.

**Lapageria rosea.**—Of this useful and free-flowering greenhouse climber I recently noted a very large example in the Birmingham Botanic Gardens. In the large conservatory, trained overhead from side to side and also extending many feet longitudinally, the plant in question formed a pleasing screen, as well as a welcome shade to some other plants on the side stages. Some idea may be gathered of its size when it is known that the principal growths numbered somewhere about five dozen. Those in the centre were trained erect, others at right and left were slightly inclining to their respective positions. In this simple, yet effective, way a very large portion of the roof was furnished, and crowding was out of the question. The roots were below the floor of the conservatory, and abundant evidence was at hand that this useful climber is by no means opposed to the uniformly cool conditions of such a position. Indeed, the plant prefers a cool spot at all times to root in, and in such is more easily managed. Nearly twenty-five years ago the late

Mr. Robert Parker, in his nurseries at Tooting, grew a fine plant of the variety *superba* trained to the back wall of an unheated frame, protecting it in winter only with mats or a little loose Bracken. Under this treatment the plant made capital headway, the growths being very strong and the flowers exceedingly rich in colour.—E. J.

## WATER PLANTS IN THE PARKS.

THE parks and gardens of large towns are more interesting than a few years ago. There are hardy plants worth looking at now, and it is not unusual to see them massed in a bold way, but little is done with the many beautiful water plants from our own streams and other lands. We were looking through several parks about London lately, and in not one instance was advantage taken of the water margins for the many lovely things that would thrive there. At Battersea some attempt is made in this direction, but not sufficient. This phase of English gardening must be thoroughly carried out and a proper selection of things made, not getting a lot of weedy Rushes and so forth, that choke other less vigorous plants. But the ugly flint or stone margins must be got rid of. At Dulwich a black looking flint is used, and gives one the impression that the water is as dirty as many a foul stream. Of course under such conditions the beautifying of the margin is impossible; one cannot plant in a stone edging, and in the pretty, well-planted Ravenscroft Park, near Hammersmith, stone is also used. It gives the "lake," as it is called, an artificial look, like one sees in many private gardens, where ugly fountain basins and such undesirable and unsightly features unfortunately exist.

In most parks there are opportunities for the growth of water plants, or those that love the moisture of the stream-side. First in importance is the Water Lily, and the mass of the common white kind, *Nymphaea alba*, in Battersea Park shows how much can be accomplished in this way. There is no want of variety. One could have such fine kinds as the broad pure white-flowered *N. alba candidissima*, rosea, varieties of the beautiful *N. odorata*, as the yellow-flowered *N. o. sulphurea*, and when they become more common, some of the splendid hybrids raised by M. Latour-Marliac, flowers that combine the beauties of the Eastern Water Lilies with those of northern climes—plants vigorous in growth, and with flowers of many glorious tints. The blossoms of some kinds measure nearly a foot across. People do not know of these lovely water flowers waiting for them—flowers that are not poor in growth or difficult to grow, but as hardy as our own white Water Lily and quickly increasing.

Apart from the Water Lilies, a wealth of native plants is at command. The Bog Bean (*Menyanthes trifoliata*), the Arrow-heads (*Sagittaria*), the Water Violet (*Hottonia palustris*), the Water Crowfoot (*Ranunculus floribunda*), the charming Bladderworts (*Utricularia*), Water Forget-me-not (*Myosotis palustris*), and a host of other things. A glorious native Buttercup is as rare almost in gardens as the Water Lily. We mean the *Ranunculus Lingua*, a noble yellow flower, with glaucous leafage and blossoms each about 2 inches across, the colour glistening yellow.

Many things are available for the margin of the water where the Siberian, Kämpfer's, and yellow Water Irises are at home; the Globe Flowers (*Trollius*), the Loosestrife (*Lythrum*), and the *Epilobium* (Willow Herb), besides many other plants. Water gardening is new almost to many people, and we have yet to learn that it is as interesting and as beautiful as any other phase.

**DRACÆNA AUSTRALIS AT TRESCO.**  
 In many favoured Devon and Cornish valleys *Dracæna australis* may be found in a flourishing condition, for, provided the climate be suitable,

it is not particular in the matter of soil. In no part of Great Britain, however, can it be seen to such advantage as in the Isles of Scilly, the Western Islands, which lie in the embrace of

the Gulf stream and in the rays of the setting sun as one looks out across the Longships from Land's End. Of all these islands, Tresco is the one which is *par excellence* the home of the *Dracæna*. Tresco can be easily reached by boat from Hugh Town. St. Mary's, the metropolis of the Scillies.

In the gardens of Tresco Abbey are *Dracænas*, sometimes in avenues, as shown in the accompanying illustration, sometimes single giants standing alone with a carpeting of Poet's *Narcissi* in the spring or of *Hydrangeas* in the autumn, sometimes thrusting thick stems out of an undergrowth of flowering shrubs.

Here Palms expand their spreading fans in blissful oblivion of degrees of latitude, and one can hardly refrain from a regret while admiring their luxuriance that when, in the dark ages of the world, the Phœnicians gained the breaker-bound shores of the Cassiterides in their Cedar-built galleys, they were not greeted by the wavy leaves of the Palms from which they themselves derived their name; but at that period it is unlikely that anything but indigenous vegetation flourished in the Tin Islands. Here long lines of flowering *Aloes* lift their candelabra to the sky, reminding one of the journey along the "Flats" from Cape Town to the vineyard-land of Constantia. Here the polished smoothness of a *Musa's* leaf or the graceful fronds of a *Tree Fern* take one back to the West Indies—to Trinidad, and to Kingsley's adoration of the tropical foliage of that pearl of islands as expressed in his "At Last."

On every side is something to remark and to remember—tall specimens of *Fourcroya longeva*, with spikes over 20 feet in height; Australian *Wattles*, blooming as they do in the Riviera and in Algeria; *Eucalypti*, *Camellia* trees and *Edwardias*, *Rhododendrons* of every shade of colour, *Boronias* and *Correas*.

In the spring acres of *Narcissi* diffuse their scent on the warm, salt breezes, and in the summer the gardens are ablaze with *Mesembryanthemums*, *Geraniums*, and *Kalosanthes*. Amongst the ancient tombs in the ruined abbey the *Lily of the Valley* blooms, and the *Agapanthus* lifts its tall umbels of blue and white blossoms within the ivied walls and arches. The New Zealand *Flax* grows in the Scilly Isles as rampantly as in its native habitat, and the South American *Rheas* stalk contentedly near the short Grass of the meadow beneath the abbey.

As, in the evening, the boat leisurely proceeds to St. Mary's on the homeward journey, the sound of the oars in the rowlocks echoes afar in the silence of the calm. The breasts of the sailing gulls reflect the blue-green of the sea, and a seal, noiselessly raising head and shoulders from the waters, gazes contemplatively at the intruders on its domain. There is yet time after landing to watch the sunset from Garrison Hill ere the tall Bishop's Light flashes its guardian rays over the Western Islands and the sleeping Atlantic. S. W. F.

**Gardens in and around Norwich.**—Norwich is known in literature as the "city of gardens," and it certainly merits the title. In no place have I ever seen more enthusiasm displayed in flower and window gardening. At this season a wealth of floral beauty may be seen, no matter in what direction one turns, the windows of many of the humbler cottages being quite miniature

An avenue of *Dracæna australis* in the gardens at Tresco Abbey. From a photograph by Lord Annesley.

greenhouses. Stocks, Asters and Gladioli are exceedingly well cultivated in the suburbs, and I was much pleased with the fine display of Verbenas I saw in one garden, the purple, white and scarlet varieties being equally well represented. The demand for jobbing gardeners during the summer and autumn months must be great, judging by the great number of well-kept villa gardens. I had the pleasure of visiting the fruit and vegetable market, which is undoubtedly one of the finest in the kingdom, both as regards convenience and the quantity and quality of the products offered for sale. One thing which always strikes me is the late supply of Raspberries. Whether these late fruits are obtained from the autumn-fruiting varieties, such as Belle de Fontenay, or from ordinary varieties, cut down in spring and induced to yield in autumn, I cannot say. Perhaps the cool moist nature of the climate has something to do with it. Currants, again (both Black and White), are offered in Norwich market much later than in most places, better prices of course being realised than during the ordinary Currant season, when gluts invariably occur.—J. C.

## FLOWER GARDEN.

### NOTES ON CHOICE HARDY PLANTS AT OFFINGTON.

VERY few gardens indeed contain such an extensive collection of rare hardy and half-hardy plants as is to be found at Offington, near the Sussex coast. Even the most casual observer when visiting the gardens cannot fail to notice that here no effort has been spared to collect all that is rare or choice among hardy plants or such as can be grown successfully by only slightly protecting them during winter. At the beginning of August I visited this most interesting garden and was conducted over it by the genial owner himself, who naturally takes a great pride in the many treasures in his possession.

Just before reaching the front door one passes a south wall so densely covered by vegetation, that scarcely a stone is visible. Here, in spite of the summer being far advanced, many choice and rare plants were still in bloom, amongst them being *Indigofera floribunda*, with its handsome racemes of rosy crimson flowers and nearly 10 feet high; the pink Tree Mallow (*Lavatera Olbia*), the deep claret-coloured *Swainsonia atro-purpurea*, and a fine plant of *Hedysarum multijugum*, the largest I have ever seen, measuring 10 feet high by 6 feet broad. This plant was planted against the wall just after its introduction, when it was considered a tender plant, but that it is perfectly hardy everywhere without the shelter of a wall has since repeatedly been proved. The same wall contains many choice things whose flowering season is past, but which nevertheless are most attractive on account of their foliage, such as *Actinidia Kolomikta*, described in THE GARDEN, August 24; *Ozothamnus rosmarinifolius*, the Australian *Templetonia retusa*, *Viburnum suspensum*, *Actinidia arguta*, *Rosa moschata* (10 feet high). *Stranvæsia glaucescens* (6 feet to 7 feet), a fine specimen of the Groundsell Tree (*Baccharis halimifolia*), measuring 12 feet by 10 feet, and most effective even now, although not in bloom. *Vitis amurensis* is also doing well. The house is covered with many interesting creepers, one of the most effective being *Lonicera gigantea*, with large panicles of yellow tubular flowers fully open at the time of my visit. A walled enclosure near the house has on the north side a fine specimen of *Hydrangea scandens*, and on the south side

may be seen *Acacia dealbata*, *Poinceana Gillesii*, *Edwardia grandiflora*, *Diospyros Kaki*, *Vitis humulifolia*, and *Eriobotrya japonica*. On the same wall I saw to my great surprise a most vigorous plant of *Lagerstremia indica* covering a space quite 10 feet wide and the whole height of the wall. This plant, known to most of us as requiring the temperature of an intermediate stove, has here been flourishing in the open for years, receiving only very slight protection in winter. A fine border plant in the same enclosure is *Stevia Eupatoria*, which forms a bush about 4 feet high by 3 feet in diameter, and bearing loose corymbs of white flowers.

At a little distance from the house and on the east side of the flower garden is a walled garden of considerable size, and devoted almost entirely to choice hardy plants. In the centre is a rockwork, which, though on an unpretentious scale, contains, nevertheless, some very choice plants in good condition, and among those still in bloom were *Myosotis Welwitschi*, a lovely late-flowering *Forget-me-not*, *Pelargonium Endlicherianum*, *Convolvulus mauritanicus*, *Saxifraga Hirculus*, *Pteroccephalus Parnassi*, *Hypericum Coris*, *Campanula isophylla alba*, *Horminum pyrenaicum*, *Chrysogonum virginianum*, and many others. In the same rockwork a plant of the African *Saintpaulia ionantha* is planted out, but I very much doubt its proving hardy during winter even in that sheltered locality.

The borders of this walled garden contain many treasures. The *Hydrangeas* are magnificent specimens, and to these I devoted a special paragraph in THE GARDEN of August 24. The following choice plants which at the time of my visit were in full bloom have also been separately described in the same issue: *Senecio Heritieri*, *Sutherlandia frutescens*, *Solanum arboreum*, *Campanula Vidali*, *Roscoea sikkimensis*, *Platycater Sieboldi*, and *Polygonum filiforme variegatum*. These, however, form only a very small proportion of the many choice things to be found. The deep yellow *Cassia corymbosa* is in full bloom and forms a spreading mass of glossy leaves which still enhances the beauty of the blossoms. The plant covers a wall quite 9 feet high; it stood the last severe winter, but for better protection its shoots had been tied into a bundle. Here also are to be seen *Doryphera sassafras*, *Indigofera alba*, and the beautifully variegated *Acanthopanax spinosissima variegata*. *Lespedeza bicolor* is just opening its pendulous racemes of rosy purple flowers, while *Dolichos arcosanguineus* has finished blooming and is displaying its large curiously-shaped seed-pods. Here I may also mention *Pittosporum sinense*, *Veronica Lewisi*, *Symplocos cratægoides*, *Senecio Grayi*, *Hovenia dulcis*, *Ilex decidua*, *Asparagus verticillatus*, and *Anthyllis Barba-Jovis*, all of which are very rarely met with in gardens and are looking exceedingly well.

A rocky border near a conservatory contains masses of the pretty annual *Arnebia cornuta*, and against the conservatory itself grows a fine specimen of *Xanthoceras sorbifolia*; this, by the way, is perfectly hardy throughout the southern counties and should be much more extensively grown. Not only are its flowers and foliage highly ornamental, but its fruits (about the size of Apples) are abundantly produced. In spite of the last severe winter it is fruiting profusely in Messrs. Veitch's grounds at Exeter, while the specimen at Offington here referred to is quite 14 feet high and covered with large clusters of fruit. Near the same conservatory grow fine specimens of *Crinum Powellii*. The large pink blossoms, at the time of my visit fully developed, are borne about eight

flowers in an umbel and on stems 2 feet to 2½ feet in height.

Against a wall close by grows *Mutisia decurrens*, 8 feet high; *Rosa gigantea*, from Burma; *Ceanothus azureus* and *Pourthia villosa*. Against the Orchid house grows a fine plant of *Leptospermum stelligerum roseo-album*, with its white and pink flowers, covering a space of about 6 feet by 4 feet; and *Drimys Winteri*, *Phlomis floccosa* and *Desfontainea spinosa* are also well represented.

In a broad border near the flower garden a most effective display is produced by masses of *Castilleja indivisa*. Why is not this exquisite showy flower more extensively grown? It is only an annual, it is true, but the large scarlet-crimson bracts, borne on stems about 18 inches high, are at present by far the showiest thing in the garden, whilst for cutting for indoor decoration few flowers can equal it in brightness of colour. Close by the flower garden is also a border specially devoted to choice hardy shrubs. Conspicuous among others are *Quercus cornuta*, with peculiar broad leathery leaves, *Rosa microphylla*, with its double red flowers, *Aplopappus ericoides*, *Abutilon vitifolium* in bloom, *Daphniphyllum glaucescens*, the scarce *Comarum Salesovianum*, *Exochorda Alberti*, and many others.

In another part of the gardens are *Ostrowskia magnifica*, *Azalea roseiflora*, and many other gems, but to give even a mere list of names alone of the plants in this garden would occupy more space than is here at my disposal. Suffice it, therefore, to say that the collection at Offington must rank amongst the foremost in England, and is certainly one of the most interesting I have ever seen.

Exeter.

F. W. MEYER.

**A rare Bindweed at Venice.**—A friend tells me of a very beautiful *Ipomæa* now in bloom in the garden of the monks of the Armenian monastery on one of the islands near Venice. The flower is described as being 3 inches to 4 inches across, of a greenish white colour, and having a dark purple throat or eye. Can it be *Ipomæa albivenia*, an evergreen species from Algoa Bay? If any resident in Venice or any visitor there would kindly tell me the name of this fine species, or, better still, obtain seeds or roots of it, I should be much obliged.—F. W. BURBRIDGE, *Trinity College Botanic Gardens, Dublin*.

**Herbaceous Lobelias.**—As there has during the last year been much correspondence on the subject of herbaceous Lobelias, I send herewith a spike grown with absolutely no protection during the winter. Two clumps were procured in the autumn of 1892 which have now been divided into twelve. They have been left in the bed all the year round and have had no mulching, even in the severest and most prolonged frosts. The spike I send you is, although all the flowers are not as yet expanded, over 4 feet 7 inches in height and 3 inches in circumference at the base, and shows that in some soils the practice of non-interference pays with these plants. In the low-lying ground in which the clumps in question are growing 21° of frost have been registered since they were planted.—S. W. F., *Torquay*.

**Japan Anemone Lady Ardilaun.**—As far as I have been able to judge, this is an improvement on the old form, but I am afraid that it is not likely to be so reliable. I got my plants from the raiser and put them out in good time. Early in July black spots appeared on the foliage and these gradually extended, so that the older leaves are much discoloured, thus lowering the vigour of the plants and marring their appearance. The spring was very hot and dry, and this may be the cause of the discoloration, although I kept the plants well watered. Some quite young plants that were set out on a north border are fresh and

green, so that it would really appear that this Anemone is liable to be affected by hot parching weather. In my case it cannot be soil, for close by, the variety Whirlwind is growing as freely and is as healthy as the type. Your readers who have grown this Anemone will have been able to form an estimate with respect to its value as a reliable garden flower, and I should like to know if anyone has had a similar experience to mine. It would be a pity if this and other new varieties should have an element of weakness in them, for it is the complete hardiness and freedom from disease that render the old forms of this flower so valuable for open-air decoration.—J. C. B.

THE RHUBARBS FOR USE AND BEAUTY.

To speak of the Rhubarb plants in many, if indeed not in the majority, of cases merely calls up a vision of the esculent species, Rheum

raised at Elford by Mr. Buck. This has a scarlet skin and red flesh, which retains its colour after cooking, and as it colours in the dark when forced, it is showy and sells well in the market. Mitchell's Royal Albert and Dancer's Early Scarlet, with Myatt's Linnaeus are other good market varieties, as is also the giant kind known as Myatt's Victoria, which produces enormous petioles or leaf-stalks. The young flower-stalks when they first appear may be cut at 6 inches or so in length and can be boiled like Cabbage as an early green vegetable. It is not unlike Cabbage or greens in flavour, but has a slight and pleasant acidity all its own. The amount of Rhubarb grown in the vicinity of all large towns is marvellous. Near Leeds this culture is really an important industry, both as forced with manure or fire-heat and as grown in the open-air beds. Apart from its use as a fruit substitute in the way of puddings,

it has since formed a crop of some considerable importance at Badicott, near Banbury, and its roots are medicinally employed. R. Rhaponticum is also grown at Badicott for its dried roots, but the great bulk of our medicinal Rhubarb is imported from India, Russia or China. Some 625,000 lbs. of Russian or Chinese roots are sent annually from Hankow to Shanghai, and the total import of roots into the United Kingdom is estimated at 350,000 lbs.

All the species of Rheum are very ornamental as grown in bold groups or masses in suitable positions. They thrive best in a deep, rich, moist and well-manured soil, and may be easily increased by seed or by division of the spreading rhizomes. The best time to divide or to replant all the kinds, useful or ornamental, is in April or May, or just as the growth naturally commences to develop, as thus moved carefully during wet weather, or if watered copiously, the plants suffer but little, if any, check, and grow all the more vigorously for their removal into fresh soil. The rarest and most remarkable of all the ornamental kinds is

R. NOBLE, found growing on rocks and terraces of mountains in Sikkim. Its tall flower-stems are clothed with soft yellow or primrose-coloured bracts, closely related or imbricated over each other. This noble species has flowered in the Royal Botanic Gardens at Edinburgh, where many seedlings were raised some years ago.

R. EMODI is another giant species, with puberulent reddish stalks, gigantic flower-spikes, and broad leaf blades. It is from the Himalayas, and as well grown near to a pond or stream often is 10 feet high when in bloom.

R. acuminatum, from Sikkim, R. australe, from Nepal, and R. undulatum, from Siberia, are other good kinds, but the form of R. palmatum called tanguticum, with incised leaves, purple-red beneath, and flower-stems 10 feet to 12 feet in height, is one of the best of all the ornamental kinds as boldly grown and grouped in deep rich light soil. As R. palmatum naturally extends as a wild species over a considerable area in Eastern and Northern Asia, it follows that it exhibits considerable variety, but all its

seedling forms and phases are beautiful if well and strongly grown.

It is very curious that Rhubarb, although long grown in France for ornamental purposes in flower-beds or on lawns, is but rarely, if ever, used for cooking. One phase of Rhubarb beauty is the intense crimson colour of the long shoots and leaves as they push through the ground in early spring, followed by the towering plumes of white flowers, which again are succeeded by crimson-red panicles of fruit and gigantic foliage, that is almost as effective as that of the Chinese Gunneras.

F. W. BURRIDGE.

Rheum officinale in the garden at Castlewellan. From a photograph by Lord Annesley.

Rhaponticum, our common garden Rhubarb, and the "Pie Plant" of the United States. This plant originally came from, or at least is found wild in, Eastern Siberia. It is known to have been grown at Padua early in the seventeenth century, and from thence it was brought to England about 1628. The roots or rhizomes of this species and its varieties are cultivated for medicinal uses at Badicott, in Oxfordshire, but its main importance is as a vegetable substitute for fruit early in the year, many tons of its half-blanching leaf-stalks being forced and sent to market from December to April every season.

Of Rheum Rhaponticum, there are many garden forms, these doubtless being selections from seed which is freely produced if the tall flowering spikes of fleecy white flowers are allowed to develop. These varieties vary much in precocity as also in size and colour of the leaf-stalks. The best kinds are Tobolsk, an early variety good for forcing, and Elford,

pies or tarts, the stalks in autumn are often utilised for preserving in sugar with the addition of lemon juice and parings of lemon rind. A preserve made by mixing autumn Rhubarb and Blackberries or Rhubarb and Vegetable Marrows, or even with Apples, is by some housewives much appreciated.

That the dried or powdered rhizomes of several species of Rheum or Rhubarb form a valuable medicine has long been known. The species that yield the best supply may be mentioned in the order of their acknowledged importance: R. palmatum, first found growing wild in the province of Kausu, in the extreme north-west of China, from whence it has long been known that the best dried Rhubarb roots were imported; R. officinale (the fine species shown in our illustration), second only in importance, being a noble perennial herb found wild in Eastern Tibet near the Chinese frontier. Introduced, or rather first grown for economic purposes by the late Mr. D. Hanbury in 1873,

Single Dahlias for cutting.—With the possible exception of Cactus Dahlias on long stems one must admit that the singles form the best class of Dahlias for cutting; in fact, the wonderful freedom of flowering which is characteristic of them gives a marked advantage over any other type. Many persons dislike them, however, be-

cause they find that the petals often fall off soon after cutting. This is entirely due to the flowers not having been cut when young and fresh. The stage of the flower's expansion can be easily seen by observing the centre. If the disc has not shed its pollen the blossom will stand well and endure a very long journey unharmed. Those who complain of the fleeting nature of the single Dahlia and its consequent unsuitability for cutting will find that if the blooms are properly selected and only cut in the fresh state just described, they will be rewarded by seeing them last as well in water as the Cactus Dahlia. Again, if the flowers are cut when old they will be found to have faded and to have quite lost the brilliancy of colour seen on those recently expanded. They should also be cut early in the morning or late in the evening when the blooms are still and fresh and have recovered from the effects of a scorching sun.—H. A.

*Bupthalmum salicifolium* is a small, hardy, herbaceous perennial worthy of a place in every garden. It makes an excellent border plant, being neat and showy. It thrives well in ordinary garden soil, attaining a height of about 1 foot, and is smothered with its golden yellow flowers during the summer and autumn. The flower is very distinct, resembling that of *Rudbeckia Newmanii*, but slightly smaller. The black disc of the latter is also lacking, the disc in *B. salicifolium* being yellow in colour, thus giving a very distinct character to the flower. Altogether, this is an old plant which should certainly be more popular.—H.

#### VERBASCUM CHAIXI.

THOUGH the names and the characters of various species of Mullein are much confused, I think I may safely say that *V. Chaixi* (Villars) (see p. 98) never yet grew 8 feet high in any soil. Eight decimetres—about 2 feet 6 inches—is the extreme height assigned to *V. Chaixi* in Grenier and Godron's "Flore de France;" adding half as much again for luxuriance in cultivation, we may fix about 4 feet as the limit it is likely to attain in gardens. But, except at Kew, I have never seen the true *V. Chaixi* (Villars) in cultivation in any English garden. Two plants often assume the name; one is *V. Wierzbicki* (Keuffel)—syn., *V. vernale* (Wierzbicki)—which grows 8 feet high in my garden. The other is our native *V. nigrum*, which I have never seen more than 6 feet high, from 4 feet to 5 feet being a commoner height in cultivation. Why this latter plant, of which our native flora has good reason to be proud, is so often exhibited in nurseries under the name of a less ornamental exotic I can never understand. In "Flore de France" of Grenier and Godron we have the descriptions of *V. nigrum* and *V. Chaixi* given side by side, and except that *V. Chaixi* is one third less in stature and size, it is difficult to pick out any obvious difference. In *V. nigrum* the stalk is angular, in *V. Chaixi* it is round. In *V. nigrum* the pedicel is twice as long as the calyx, in *V. Chaixi* it is equal in length. I do not assert that all the hundred examples of *V. nigrum* in my garden agree in having these distinctive characters, but I am quite certain that all of them, including the variety with white flowers, are the very plants or the off-spring of the plants which were collected wild by me in the valley of the Thames; therefore, none of them is *V. Chaixi*. It is quite a mistake of botanists to call *V. nigrum* a biennial. It is as perennial as an Oriental Poppy or a Dandelion, and comes up in the same way from pieces of root left in the ground where it has been dug up.

The white-flowered variety which I found wild near Burnham Beeches is one of the most ornamental of hardy border plants, and if isolated comes true from seed. It is often called in nursery catalogues *V. Chaixi album* (syn., *orientale*), though E. Boissier, in his "Flora Orientalis," says that *V. orientale* is quite distinct from any European Mullein. In conclusion, I recommend the cultivation of Mulleins if only for the

very ornamental hybrids they produce in gardens, hybrids often superior to either of the parents.

*Edge Hall.*

C. WOLLEY-DOD.

#### SINGLE CACTUS DAHLIAS.

WHEN recently at Rothesay I had an opportunity of inspecting the extensive collection of Dahlias cultivated by Messrs. Dobbie and Co., the well-known seedsmen and florists, and gained some idea of the extent to which Dahlias are grown in the north. While the show and fancy varieties (with the pompon and single kinds) are largely grown, the single Cactus varieties most attracted my attention.

I may refer to the ordinary single Dahlias to say that if they are a declining floral force in the south they are still in great demand in the north, judging by the extent to which they are grown in Messrs. Dobbie's nursery. But they have to face a serious rivalry in the single Cactus type, which Messrs. Dobbie and Co. have done so much to improve; and they are so original in shape and novel in appearance and so well adapted to the wants of those who dislike flowers of more formal shape, that I venture to predict for them considerable popularity.

In setting forth their good qualities one of the leading ones is their habit of growth. Here they are in direct contrast to many of the varieties of the double Cactus type. How few of these there are the which, by reason of being free of bloom and of throwing their flowers well above their foliage, are adapted for garden decoration. Some of the most beautiful—delicate especially—are the worst offenders in this respect, though it should be stated that the more recent novelties do show some marked improvement in habit. The new single Cactus varieties are the very reverse of this, for they, with but very few exceptions, have fairly dwarf and compact habits of growth, they are singularly free of bloom, and throw their flowers well above the foliage. In addition, the blooms are generally on erect stems, and so are well adapted for indoor as well as outdoor decoration. For indoor purposes the flowers should be cut just before they are fully matured. In form and appearance the flowers have a striking yellow and circular disc and from six to eight petals, which curl back at the sides, become largely tubular, and so take a shape that, bereft of mere formal flatness, admirably fits them to be effective in floral decorations—in vases, on the mantel-piece, and in the many ways in which Dahlia blooms can be employed in the household. Seedlings are raised every year, so that the work of improvement may not lag. We are indebted to Mr. E. J. Lowe for the introduction of the type. He saw in it, if properly developed, possibilities of great usefulness. Messrs. Dobbie and Co. were the first to take the flower in hand, and they are rapidly improving it year by year. They have this season nearly 1000 plants of single Cactus Dahlias, including a margin of seedlings. A few of the most promising of the named varieties already in commerce will be found in Alice Lee, pink, paling to white at the base of the petals, very pretty indeed; Anne of Gierstem, peach, flushed with salmon and shaded with violet, very pleasing; Lady Rowena, sulphur and salmon-rose, a charming combination and very distinct; Marmon, glowing crimson-scarlet, very showy and distinct; Peveril, deep terracotta colour, shaded with dark cerise, very free; Argyle, deep maroon-crimson, which contrasts with the deep golden disc; Bruce, pale creamy lemon, a charming variety; Lochiel,

cinnabar-red, the florets slightly incurved; Novar, crimson-purple, shaded to magenta, very good indeed; and Queen Mary, pure white, with pale yellow disc, very pleasing indeed, and admirable for cutting. These represent the very cream of the newer introductions.

Of older varieties, Earl of Ravenswood, old gold colour; Guy Mannering, creamy white and sulphur; Highland Mary, clear cardinal-red; Ivanhoe, bright lilac-rose with crimson band round the golden disc; Lucy Ashton, white, broad petalled, very pleasing; Meg Merrilies, clear yellow, very good; and Rob Roy, purple with violet shading, are all very attractive. There may be differences of opinion in relation to the ordinary single Dahlias as to whether the florets should recurve or be cupped; beyond this the only variation is in the colour and marking. But these single Cactus types admit of considerable variation in point of shape, in the breadth and length of the petals, some spreading themselves horizontally and some incurving, and so the tastes of many may find satisfaction.

It is always well at a time when any particular type of flower is in bloom to make selections of the best. This I have done in the case of the single Cactus Dahlias when I saw them in bloom and could note habits of growth. In this last respect the general characteristics are so good that there need be little misgiving in reference to the general adaptability of this type to effective garden decoration.—R. D.

—This distinct type of Dahlia of recent introduction is very welcome to those in search of cut flowers for vases, table decoration, &c. For such purposes it is well adapted, and is better, on the whole, than any of the other sections of Dahlias. It is also a decided variation from any flower at present in general use for such purposes, and is characterised by such extreme lightness as to render it almost always possible to employ it for decoration. Its lack of formality should ensure for it a wide range of popularity. For garden decoration, too, it will be found useful, though the amount of display will not equal that given by the ordinary single Dahlia. The colours of the varieties already raised embrace a wide range. Of new varieties I may mention Alice Lee, a combination of white and pink, with twisted and incurved petals; Kenilworth, rose, streaked with white, with twisted petals; and Lady Rowena, sulphur, tipped with salmon-rose, good habit.—H.

*Campanula isophylla alba*.—Where a plant of trailing or drooping habit is required there is nothing to equal this. Commencing to flower quite early in the summer, it will keep up a succession for many weeks. Few things are so easily managed as this, and few, indeed, so well adapted to such a variety of circumstances. Suspended in the window of the cottager as a pot plant it is excellent, and the same may be said of it for the rockery, for window boxes, and for any and every position where trailing plants may be employed with advantage. Singularly enough, it thrives amazingly in either sunny or shady windows, though in the latter position the blossoms are rather longer lived. This is of little moment, however, as the flower-buds develop so rapidly that the plants keep up a continuous mass of blossom of the purest white. Only plant it in a fairly good soil, and with occasional watering success is ensured. While writing I have in my mind's eye some splendid masses of this plant in window boxes. There are some half dozen plants, two in each box. Individually the plants are nearly 18 inches across, of about equal size, and forming perfect sheets of bloom. To my knowledge these same plants have been in full flower for the past six weeks, and the hundreds of buds present promise a supply of bloom for a like period. Is it not rather surprising that any such plant

capable of a three months' display, with hundreds of blossoms expanded daily, should only be seen here and there? A plant of such easy culture as this, hardy and free flowering withal, has no equal among trailing subjects, and deserves extensive cultivation.—E. J.

**Calystegia pubescens fl.-pl.**—This is undoubtedly one of the most beautiful of all herbaceous climbing plants, and as a free-flowering, perfectly hardy, and vigorous growing subject it can be strongly recommended. The flowers are exceedingly double, of a soft and pleasing rose shade, and produced in great profusion on long trailing stems. There are many positions in the garden where its free use may give additional charm—such, for instance, as when planted at the foot of a hedge of Laurels or Holly. Over such things it may be allowed to ramble at will, or be given a trellis against the house, wall, or similar place. Planted on the higher parts of the rock garden and allowed to trail about at will, it is very pleasing. It is by no means particular as to soil, though as a rule it thrives best in a rather sunny spot. When once planted it should be left alone for several years. Indeed, it seems to prefer quite firm soil, for I remember seeing a large quantity some years ago springing from beneath a brick floor. The cottages were minus the usual bit of front garden and abutted on the street, and the above plant, springing from the paving of bricks, was climbing up strings against the cottage walls. Though not quite so vigorous as when growing under better conditions, it was, notwithstanding, growing and flowering quite freely. At the base the slender growths were protected by wire netting, a proof that its presence was appreciated.—E. J.

FLOWER GARDEN NOTES.

**BEGONIAS.**—These, to use a common phrase, have this season fairly surpassed themselves, the display where they have been well cared for being very fine and long-sustained. It is matter for congratulation that a wonderful improvement has been effected in and with bedding Begonias within the last few seasons, viz., the adoption of plants of more sturdy habit with erect or nearly erect flowers and thinner planting. For some years it seemed the aim to plant out as large-flowered varieties as could possibly be obtained, with the result that one very seldom saw the beauty of the flowers, blooms and flower-spikes being, as a rule, nearly prostrate in the dust or hidden by the foliage, and even if matters were not quite so bad as this the drooping habit of the flower prevented any more being seen of it than the outside of the petals. Under such circumstances a bed of thoroughly good scarlet or pink Pelargoniums was infinitely brighter than the Begonias, and there was the danger that the latter would gradually decline in favour. The introduction, however, of such varieties as *Worthiana* and *ascotensis* into the summer bedding proved what had hitherto been wanting in Begonias, and the skill of the hybridiser quickly gave us in the common tuberous section a type with erect flowers that are produced in great profusion, retaining, too, in the plant the fine bold foliage and sturdy habit. Two noted this year that are respectively deep orange-scarlet and cerise-scarlet, the latter somewhat the shade of Guillion Mangilli Pelargonium, are specially fine plants quite 2 feet in height and slightly over this in diameter, well clothed with foliage and simply studded with erect flowers borne well aloft on firm, strong flower-stalks. The habit of planting very thickly is now, happily, almost discarded, sufficient room being given to allow for the proper development of individual plants and to show a dwarf carpet between that will form a pleasing contrast to the Begonia; even a little soil visible here and there is better than a close huddling together of the plants. For the colours above named a good carpet is to be found in the golden *Mesembryanthemum*, *Koniga variegata*, or some of the white or light-coloured Tufted Pansies.

**UNCOMMON BEDDING PLANTS.**—The introduction of *Plumbago capensis* into outdoor flower gardening is of comparatively recent date, but it has now become a decided favourite, large plants on a dwarfed carpet, presenting possibly the most effective display. Like specimen plants of *Heliotrope*, *Fuchsia* and *Pelargonium*, the *Plumbago* should get cool treatment for a month or six weeks prior to planting out. I renewed acquaintance the other day with an old friend in the shape of *Coprosma Baueriana variegata*, large pyramids 6 feet in height and between 3 feet and 4 feet in diameter at the base; they were plunged in a large bed which had been previously partially filled with a deep crimson *Antirrhinum*; this was flowering remarkably well and set off the golden pyramids to admirable advantage. *Humea elegans* is an old favourite, and I remember very fine specimens in the flower garden twenty-five years ago. Lately, however, it seems to have declined in favour, possibly owing to the fact that a difficulty is often experienced in raising the plants. Thoroughly good seed that will come well is not easily obtainable. Late in the season when the long spikes of seed are swaying gently in the breeze it is a very attractive plant. Occasional plants make a nice break to beds of dwarf *Pelargonium*, only the latter must be kept well away from the *Humeas* that the bottom flower-spikes may have room to develop and be preserved intact. Seeding *Humeas* will now be nice little stuff, and may be transferred singly to very small pots or pricked out into seed pans or boxes, shifting again rather later in the season. It is not advisable to have the plants too large for wintering; 4-inch or at the most 5-inch pots will be quite large enough, and they can get the last shift with the approach of brighter days at the beginning of another season. When the small pots get well filled with roots it is advisable to give weak liquid manure twice a week, the *Humea* when fairly well established being a gross feeder. Writing of the *Humea* as a pot plant in connection with dwarfed subjects reminds me that I have found two hardy plants—*Statice latifolia* and *S. Gmelini*—very acceptable for a similar purpose in connection with the darker *Violas*, such as *Mrs. Bellamy*, *Crimson King* or *J. B. Ridding*. The value of the *Sea Lavender* in different styles of flower garden planting is becoming better known with each succeeding year; they are, however, as yet uncommon bedding plants. I saw an old favourite the other day in *Maurandya Barclayana*, a very fine plant as a trailer for raised beds. Planted close to the piles that support the soil and allowed to droop over them it blooms with wonderful profusion, and the colour is one not often met with in outdoor flowers. A similar position is just the place for *Convolvulus tricolor* in variety, a very beautiful annual, throwing blooms of soft and varied shades, and with a well-sustained flowering season. I should like, in passing, to direct the attention of GARDEN readers that are skilful with brush and palette to this variety of *Convolvulus*; some of the loveliest shades of colour imaginable are obtainable from a good strain of seed. In the same garden where the *Maurandya* above-mentioned was flourishing I came across the old *Cuphea platycentra* as a broad edging respectively to *Centaurea ragusina* and to a light-coloured *Heliotrope*. Although not particularly striking in appearance, the *Cuphea* makes an admirable carpet, and the bushy plants are simply covered with the peculiarly shaped flowers. As a bed out of the ordinary run, unique and at once striking and effective, let me recommend a combination of *Yucca filamentosa* and *Lobelia cardinalis*, planted respectively in bold groups. If this is done on a big scale it will be a very pleasing contrast, and may be specially recommended for a sloping lawn when there is, as a rule, a distant view of the bed.

**TUFTED PANSIES.**—In noting on page 153 a new sort certificated at Birmingham, the writer makes a very pertinent remark as to the name Tufted Pansies. Personally, I should like to see the whole section grouped under the name of perpetual or bedding Pansies, as may be deemed the more appropriate. A word in explanation,

still following the line taken on page 153. I have a splendid white that starts flowering with the earliest, and continues with no break (given proper attention) right away until October. By no stretch of the imagination can this be called a Tufted Pansy, and yet it is far more serviceable to me than *Violetta*, possibly the best of the true tufted section. Again, one of our best beds has been an association of a carpet of Countess of Kintore *Viola* with bold groups of *Pentstemons*; the *Viola* in question, as everyone must admit, is certainly not a Tufted Pansy, but one that has a splendidly sustained season if the shoots are lightly pegged and dying blooms removed. I venture to make the suggestion above-named not only as to existing varieties, but in view of the fact that many new kinds are now annually forthcoming which should either be grouped together under one name, or sent out respectively as tufted or perpetual flowering Pansies.

**PINKS.**—There is a grand strike of these favourite flowers, and where the ground is in readiness for them they could be planted out at any time. As usual the old Pheasant-eyed variety has outstripped its companions in growth, and the cuttings of this sort inserted about the middle of July are large bushy plants. It will be as well when planting out to remember that the heavy-flowered varieties, as one or two of the whites and Ernest Ladhams, are likely to require support if the weather prove stormy and wet during the time they are in flower. It is not at all a bad plan to plant such sorts with the Carnations; the display of flower on the beds is thereby considerably lengthened, and the Pinks might be propagated with the Carnations, and in a similar manner. Ernest Ladhams continues to throw occasional flowers very good in quality; this in September is another point in favour of this very excellent Pink. In connection with the better varieties of Pinks I should like to note that they make very useful pot plants, and may be employed in this way to a somewhat considerable extent, especially in those places where there is a large demand for flowers, and the accommodation for those of a tender nature is limited. Nice strong layers or cuttings that have plenty of roots can be potted up at once, using a compost of three parts open loam to one of horse droppings, well rubbed to pieces, and a dash of sand. The pots can stand all through the winter in a cold frame on a good ash bottom, and should be sufficiently wide apart, so that on the approach of severe frost the intervening space can be packed in with any dry Fern, Cocoa-nut refuse, or coal ashes; the said packing material may also stand an inch or so in thickness on the surface of the pots.

Claremont.

E. BURRELL.

ORCHIDS.

CYPRIPEDIUMS.

WHETHER considered botanically or from an ordinary point of view, this is the most distinct genus of Orchids in existence. It is easy to confound many of the genera, but anyone may tell a *Cypripedium* at a glance though not versed much in Orchids. No other has lent itself so readily to the skill of the hybridist, the number of crosses effected among the different species being simply overwhelming. In such a host of plants naturally enough there are a few that can only be tolerated on account of their botanical interest, being sombre and dull in colouring and not to be compared with an ordinary greenhouse plant for beauty. On the other hand, there are in the genus some of the most magnificent and handsome flowers imaginable. Many are almost priceless, while others are common enough to be within the reach of all, some of the earlier but beautiful hybrids now being obtainable at very low prices. The genus is very widely distributed over considerable portions of

both hemispheres, some from the colder regions, but the majority of the kinds from tropical countries. *C. Calceolus*, the English Lady's Slipper, is the species upon which the genus was founded many years ago by Linnaeus, and although practically extinct as a wild plant, this is still cultivated in collections of hardy Orchids. The pouch or lip from which this obviously takes its popular name is the distinguishing characteristic of the genus, while the dorsal sepal in most instances is also very conspicuous. But notwithstanding this there is a very great variety both in the shape and size of the flowers. For instance, the *bellatulum* group, with their segments all of about the same size, differ widely from the *caudatum* section with smallish sepals and petals elongated to a surprising extent, while the tiny flowers of *C. Schlimi* are of a totally different style of beauty from those of the beautiful *C. Stonei* or *Morganii*. Between these there are innumerable forms that to describe fully would need a volume, to say nothing of the many hardy herbaceous kinds natives of the temperate regions. Many of the tropical kinds are naturally epiphytal, but under cultivation they are found to thrive best with a fairly substantial compost. The culture of *C. bellatulum* and its allies has been recently referred to in *THE GARDEN*, and the following is not intended to apply to these. The majority of the Indian and American kinds are free-rooting vigorous plants. When first imported the greater portion of the roots will often be found to be dead, or nearly so, and the first consideration will be to induce the formation of new ones. Various modes of effecting this have been recommended. The best plan I have tried is to lay the plants out for a week or two upon a moist stage in a warm house, as this freshens up the foliage considerably. After this they are potted up into as small pots as possible, using clean crocks and keeping the base of the plant a little above the rims. They are then plunged in Moss or else a very thin surfacing is given over the crocks and lightly dewed overhead daily. Any that are naturally weak growers and difficult to establish are better without the Sphagnum, for a time at least, keeping the crocks moist by watering several times daily. As soon as roots are seen to be starting a little Moss must, however, be given, while the stronger growers may be lightly surfaced over with peat and Sphagnum mixed. This will usually suffice for the first year, and if during this time the plants produce roots plentifully, they are then, comparatively speaking, safe. Early in the succeeding spring they must be carefully repotted, avoiding snapping the roots or disturbing them more than is absolutely necessary. The strongest growers may be given a compost consisting of equal parts of good fibrous loam, peat, and chopped Sphagnum, with a plentiful admixture of charcoal or potsherds, but no sand, for although this material continues to be recommended, I have never found any but harm accrue to the plants from its use. Smaller or weaker growers will be better for the first few seasons at least without any loam, using instead equal parts of peat and Sphagnum. The drainage in all cases must be carefully attended to, filling the pots to at least half their depth and covering this with a layer of the rough portions of the Sphagnum Moss. At subsequent repottings cut away all decayed roots with a sharp knife, and pick out any of the old soil that has become sour and close. If through any cause, such as a waterlogged compost or over-watering, the plants get into a really bad state at the roots, they should be shaken clean out of the compost and all adhering parts

washed away. Carefully preserve what few roots may be still alive, and after thoroughly washing and drying them, treat them as advised for newly-imported plants, excepting as to laying them out, which will not usually be necessary. The early spring months should be chosen for this operation, but rather than leave them for any length of time in such condition, I should not hesitate to repot at any season.

All the tufted evergreen *Cypripedes* may be safely propagated by division, using a thin, keen blade to separate the rhizome and retaining a few roots to each piece. They all delight in a shady, moist atmosphere while growing, and do not like much watering overhead. At the roots, on the other hand, they can hardly be over-watered when healthy and in full growth. During winter less is needed, but even then they require much more than the majority of Orchids, and no drying off is at any time to be recommended. The temperature required by the various species differs a good deal, although many of the kinds are not in the least fastidious in this respect, and this will be best referred to under the headings of the separate species noted from time to time. Amateurs commencing their culture cannot do better than grow the cheaper ordinary kinds at first, taking up the culture of the rarer and more difficult species after some experience has been gained. They will find in them an interesting and beautiful class of plants that produce a return in flower more than proportionate to the little trouble that is needed to grow them well. H. R.

***Cattleya Luddemanniana*.**—This is a member of the *labiata* group of autumn flowering species, and though not perhaps so good as *C. Mossii*, it is nevertheless a useful plant. The contour of the blossoms is somewhat stiffer than in most others, and this is especially noticeable in the smaller forms. The ground colour of the flowers is light purplish-rose, the lip having a rich purple blotch in front and two blotches of creamy white or yellow in the throat. Like all that flower upon the current year's growth, *C. Luddemanniana* must be kept dormant after flowering, and if this is properly attended to, there will not be much cause for complaint as to its not blooming freely.

***Laelia Dayana*.**—Although sometimes grown in a cool house, it is not advisable to keep newly-imported plants or even semi-established ones too cool. Possibly after a year or two in this country they are less liable to insect attacks if grown with *Odontoglossums*, but I have never seen the growths so good as when placed in the *Cattleya* house. A nice form of this I saw recently had flowers of a rich magenta-purple, each about  $4\frac{1}{2}$  inches across. It is a dwarf growing plant, usually flowering later in the season.

***Stanhopea grandiflora*.**—The pure white, sweetly-scented flowers of this Orchid are always welcome, and one only wishes they were not so fleeting. It is probably the most free-flowering species in the genus, old and well-established specimens pushing flowers in rapid succession all through the summer and autumn months. Like all in the genus, it delights in a strong heat provided the atmospheric moisture is plentiful. If allowed to get dry and parched, red spider and its attendant evils are soon in evidence. The flowers occur on short pendulous scapes, about three or four on each. It is a native of Trinidad.

***Oncidium Gardneri*.**—This is one of the prettiest of the *crispum* section and a favourite species wherever grown. The flower-spikes are large and much branched and each bears a number of the pretty and sweetly-scented flowers. The sepals and petals are brown, edged and spotted with yellow, and the large three-lobed lip is bright yellow with marginal spots of chestnut-brown. It is a native of the Organ Mountains, in Brazil, and was introduced in 1843. This thrives

well in shallow pans or on rafts suspended from the roof either at the cool end of the *Cattleya* house or with the warmest section of *Odontoglossums*.—R.

***Pilumna fragrans*.**—When happily situated this is one of the most useful and free-flowering Orchids in existence, never failing to give a good account of itself—at least once and frequently twice in a season. It may be grown in the cool house, but the pseudo-bulbs are larger and the flowers finer if given a little more heat, or such a temperature as *Odontoglossum grande* delights in. The best receptacles for the plants are well-drained clean pots, and the compost may consist of about equal parts of peat and Sphagnum with a few pieces of charcoals. It must be firmly potted and the base of the pseudo-bulbs kept well above the rim. While growing freely abundance of water must be given, and while at rest the supply must be ample to keep the bulbs plump. The flowers are produced in loose panicles of about six or seven, the sepals and petals long and twisted, white, the lip white with a dense yellow eye, a good deal like that of *Dipladenia boliviensis*. The flowers last about four or five weeks in good condition. *P. fragrans* is a native of New Grenada, whence it was introduced in 1856.

## GARDEN FLORA.

### PLATE 1031.

#### SARRACENIAS.

(WITH A COLOURED PLATE OF *S. FLAVA*.)

**SARRACENIAS** do not require any more heat than is obtainable in an ordinary glass house, where fire-heat is used only in very cold weather, and they may therefore be considered as plants that may be grown in almost every garden of any size. In *Sarracenias* we have a double attraction, viz., in the form of their pitcher-like leaves, which are often beautifully variegated, and in the large and handsome flowers which they produce very freely in the early summer months. These two characters are exceedingly well shown in the accompanying plate. In the colours of the flowers and in the form and size of the pitchers there is very considerable variety amongst *Sarracenias*, and they are certainly amongst the most attractive of plants when grown in a corner or small house by themselves, as, for instance, at Kew, Glasnevin, and in several of the London nurseries.

There are six true species of *Sarracenia* known, all of them natives of the Atlantic States of North America. *Darlingtonia californica*, a closely allied monotypic genus, is, as the name denotes, a native of California, and the very remarkable *Heliophora nutans*, also a near ally to *Sarracenia*, is limited to the Roraima Mountain, in British Guiana. Although frequently attempted, no one has succeeded in obtaining a cross between *Sarracenia* and *Darlingtonia*, and it is very likely that some functional barrier will prevent this from ever being accomplished.

***S. PURPUREA*** is the best known, the longest cultivated, and the hardiest of the species; it has short horn-shaped, inflated pitchers of a deep blood colour when mature, the flap-like lid upright, so that rain easily falls into the pitchers. When well managed this sturdy plant forms a very attractive specimen. In a 10-inch pot a plant with at least thirty large crimson pitchers upon it has been grown, and in the spring these were accompanied by numerous large red-purple flowers.

***S. DRUMMONDI*** has erect trumpet-shaped pitchers 2 feet or more long, the lid broad and

\* Drawn for *THE GARDEN* in Messrs. Sander's nursery at St. Albans by H. G. Moon. Lithographed and printed by Guillaume Severeys.

way, the whole of the upper part being creamy white with a thick reticulation of reddish and green veins; the flowers are 4 inches in diameter and have dull red sepals, maroon-coloured petals, and the stigma, which is 3½ inches across, greenish red. It is still one of the most beautiful of all *Sarracenia*s.

*S. RUBRA*.—In this the pitchers are erect, 1½ feet to 2 feet high, with a tail-pointed, inflexed lid; they are green with deep red veins in the upper part, where in autumn they assume a uniform vinous colour. The flowers are 3 inches across and coloured reddish brown.

*S. FLAVA*.—This is the tallest-growing kind. Pitchers of it which measured 3 feet 3 inches in length have been seen; they are erect, trumpet-shaped, green, the veins dark green (in some varieties red), and the lid, which is sometimes yellowish, is upright with the sides reflexed and the point tailed. The flowers, which are large, have a powerful odour, and are coloured a bright canary yellow. Some of the varieties of this, such as, for instance, *ornata* and *atrosanguinea*, are great improvements on the type, the former being very large and wide-mouthed in the pitcher; *atrosanguinea*, as the name implies, is remarkable for the deep red of its veins and lid.

*S. PSITTACINA* is a small plant with small horizontal pitchers, which have a broad wing like a knife-blade, a hood-like lid, and the apex of the pitcher so twisted as to give it the appearance of a parrot's head, hence the name. The almost transparent sides of the pitchers, with their numerous blotches of dark red, are pretty characters in this plant.

*S. VARIOLARIS* is the least attractive kind, and is not so easily kept in health as the others. It has pitchers 1 foot high, with a broad wing and a hood-like lid, and they are green with a little yellow mottling about the mouth. The flowers are large and pale primrose-coloured.

In several of the species there is considerable variation in the size and markings of the pitchers, but they all bear the stamp of their respective types, the descriptions of which about cover the characters of the varieties.

We come now to the hybrid sorts. The last species introduced was *S. psittacina*, which Messrs. Veitch distributed in 1866, and from that time till 1874 no additions to the genus were made. In 1866 it was stated that seedling *Sarracenia*s were unknown in this country. It remained for the late Dr. Moore, of Glasnevin, to not only succeed in raising plants from seeds, but also to obtain the first hybrid *Sarracenia*, which he exhibited in 1874, and which was named

*S. MOOREANA*. The parents of this beautiful plant were *S. Drummondii* and *S. flava*, and the characters of the two are blended in the offspring in the most perfect manner. The pitchers are large and richly veined, and the flowers are each about 3 inches across, their colour being crimson, pink, and yellow.

*S. POPEI*.—This was obtained at Glasnevin by crossing *S. flava* with *S. rubra*. It is most remarkable because of its flowers, which are 4 inches across, and coloured rich velvety crimson, with yellow margins, and pink inside the petals.

*S. STEVENSI* was obtained from *S. purpurea* crossed with *S. flava*, and originated at Trentham, under the care of the late Mr. Stevens. It is one of the finest of all Side-saddle flowers, growing into very large specimens, and holding its pitchers perfect much longer than any other kind. The pitchers are nearly 2 feet long, erect, broad, with a prominent wing, a large, almost round, lid, and coloured green with a reticulating nervation of brownish red. The flowers in this are also exceptional, being as much as 6 inches across, the sepals green with brown edges, the petals crim-

son outside, cream-coloured within, and the style, which is 3 inches across, bright green.

*S. WILLIAMSII* is an imported plant, and is supposed to have sprung from *S. purpurea* and *S. flava* in a wild state. The pitchers are shorter than in *S. Stevensi*, but similar to those of that variety in shape; whilst the flowers are 5 inches across and coloured reddish brown on the sepals, rosy lilac on the long petals, the large disc of the style being green. The contrast between these colours is peculiarly attractive.

*S. PATERSONI* was raised by Dr. Paterson, of Bridge of Allan, and is a cross between *S. purpurea* and *S. flava*. Except in the rich deep crimson colour of the upper part of the pitchers, there is little difference between this and *S. Stevensi*.

*S. CHELSONI*.—The parents of this were *S. purpurea* and *S. rubra*, and it was raised by the Messrs. Veitch in 1877. The pitchers are each about 1 foot long, broad, as in *S. purpurea*, almost erect, and coloured a rich claret purple. The flowers are 4 inches across and purplish brown in

*Sarracenia variolaris*.

colour. It is a handsome kind, and may be described as an elongated and improved *S. purpurea*.

*S. MELANORRHODA*, also raised by Messrs. Veitch, was obtained from *S. purpurea* crossed with the fine hybrid *Stevensi*. In habit it is like *S. purpurea*, the pitchers being 6 inches long, with a deep wing; colour rich blood-red.

*S. FORMOSA*, a hybrid from *S. psittacina* crossed with *S. variolaris*, has pitchers 6 inches high and coloured green, with reddish spots and veins. The pitcher is covered by the lid, as in *S. psittacina*, which it also resembles in the habit of the pitchers being almost horizontal.

*S. COURTI* was raised by the late Mr. Court, in Messrs. Veitch's establishment, and is a cross between *S. purpurea* and *S. psittacina*. It has decumbent pitchers, about 8 inches long, and coloured a rich deep crimson, their form being intermediate between that of the two parents.

*S. Swaniana*, from *S. purpurea* and *S. variolaris*; *S. Wrigleyana*, from *S. psittacina* and *S. Drummondii*; *S. Tolliana* and *S. Wilsoniana*, from *S. purpurea* and *S. flava*; *S. Mitchelliana*, from *S. Drummondii* and *S. purpurea*; *S. excel-lens*, from *S. Drummondii* and *S. variolaris*; *S. Maddisoniana*, of the same parentage as *S. formosa*, are hybrids, with characters partaking more or less of both parents, and are all handsome. For descriptions of these, and also of several kinds not so well known, the reader may refer to *THE GARDEN*, vol. xxviii., p. 218.

B.

## THE WEEK'S WORK.

### HARDY FRUITS!

PEACHES AND NECTARINES.—The fruits having been cleared from Early York, Early Alfred and others, much of the old fruiting wood can be cut away to get the wood matured for next season's crop, giving the new growth ample space. If attention is paid to extension of the new wood and removal of old, the trees being allowed to grow freely, they last many years. The American varieties, to get the best results, require free extension and well-matured wood. By removal of old bearing wood now there will be less pruning in the spring, and the wood if at all dirty may be better cleansed. The trees, owing to late rains, are making much growth, and unless the knife is used freely there will be soft, unripened wood and want of fruit buds. On late trees the fruit just ripening may be hastened by pinching or removing the leaves and small shoots covering the fruits. See that the trees are not deficient of moisture, as though the rainfall may be heavy, with a wide coping it may not reach the roots of large trees. Later trees should be fed with liquid manure, the growth regulated, and the fruits brought to the light to get high colour. Trees that are not worth keeping, owing to canker or other disease, should be marked and those to replace them planted early, as when the trees are got into their growing quarters early in November there will be better growth next season. Among early kinds, Alexander, Amsden June, Condor, Early Silver and Hale's Early are all good on open walls. For midseason there is a large selection, and such kinds as Noblesse, Royal George, Large Early Mignonne, Dymond, Bellegarde, Crimson Galande and Dr. Hogg are the best; whilst for late fruits Barrington is one of the best, with such kinds as Grosse Mignonne, Belle de Doue, Late Admirable, Princess of Wales and Sea Eagle. Of Nectarines, Rivers' New Early this season promises well, and the earlier introductions, such as Dryden, Humboldt and Spencer, are fruiting well. Lord Napier is all one can desire and may be grown in any soil, being the best all-round variety we have.

FIGS ON OPEN WALLS.—The severe winter having much crippled the trees, every means must now be taken to ripen the new growth. The knife should be used freely, cutting away small, weak shoots to prevent crowding, and nailing up next season's fruiting wood close to the wall to get all the warmth possible, the terminal or main branches being given every chance to develop, not shortening in any way and giving them ample space. Any old branches that have failed to break should now be removed, cutting them clean out. Shoots coming up direct from the base should be encouraged to grow freely. For new wood for extension select a few strong leaders in preference to medium-sized shoots. It is well to remove any fruits now showing, thus giving the new growths greater strength. Although fruits show freely at this season they will not winter on the trees, and should not be left, as the fruit next year will be produced from the well-ripened points of this year's wood. Growth will be later than usual owing to the late start the trees made, and will need more attention to get it well matured. Should there be any failures from old trees hav-

ing been killed, now is a good time to select strong young trees in pots, choosing those with a few strong leaders, but deferring planting till the spring. Such varieties as Brown Turkey and White Marseilles are the best.

**CHERRIES.**—Large trees should not suffer from want of moisture. Although top-growth is not active and should not be encouraged, the trees soon suffer if checked by drought, and this is the precursor of gumming and canker. Small trees inclined to make strong leaders and little fruiting wood and spurs require special treatment to check gross growth, and I prefer lifting gross, strong trees, preserving all young fibrous root growths and cutting back the strong roots. By the term lifting I do not mean it is necessary to entirely remove the tree, but to get well under it, and if necessary raise it. If done with care the leaves will not flag and the wood will not shrivel in any way. There will be a fair crop of fruit next season.

**APRICOTS** require much the same treatment as Cherries. The fruit having been gathered much earlier this season than usual, growth is well advanced and the new wood is firm. Young trees are apt to grow too strongly, especially in rich borders, and such trees never fruit freely. What fruit does mature is not good, the fruit having split stones and other defects. With young trees in the above state means must be taken to check the unprofitable growth, and there is no better time than the end of September or early next month to lift. This year, owing to the favourable summer, the growth is much more matured than in some seasons. It is not well to lift when the wood is soft, or shrivelling, which is to be avoided, would follow. Trees in light soil and on warm aspects lift better at the end of September than later, the only additional work being to damp overhead freely every afternoon in bright weather or shade for a short time if necessary. In replanting avoid manures of any kind. With gross trees rich or fresh soil may not be desirable, but such aids as burnt garden refuse, wood ashes, or in soil deficient of lime, old mortar rubble will promote a short-jointed growth and plenty of fruit spurs.

**ROOT-PRUNING APRICOTS.**—The healthiest trees are those with roots close to the surface, and to get these it is at times necessary to cut back deep-rooting coarse roots. Extra large trees may be what is termed half root-pruned—that is, half the tree done this season, the other next autumn. Should the trees operated on be poor or show signs of decay, better material, such as bone-meal or a good fertiliser, should be given the roots.

G. WYTHES.

### THE KITCHEN GARDEN.

**THINNING AUTUMN ONIONS.**—Early sowings of such sorts as White Lisbon, The Queen, and White Leviathan will now be fit for thinning. The sooner this is done the better, especially where as advised a row or two extra was sown for use in salads. The latter may remain unthinned at any rate for the present. On hard, dry ground and in absence of rain a good soaking of water should be given the day previous to thinning, or many of the bulbs will be left in the ground, which is an evil. Allow for going over the bed a second time, as one is never quite safe from attacks of the dreaded maggot. Give another moderate broadcast sprinkling of soot, using the Dutch hoe afterwards. Younger lots should also be hoed between. If the storing of ripened Tripoli bulbs is not yet complete, let it be done at once, as they lose much of their weight and quality by lying too long exposed to sun and drying winds. In forward localities the earliest lots of spring-sown Onions will be ready for pulling up. Some gardeners still follow the old plan of placing them in large flat hampers, so that they can be removed under cover at night or during heavy rains, and doubtless where time can be spared this is advantageous, it favouring a speedy and perfect maturity. My plan is first of all to throw the bulbs from one half the plot on to the other,

then clean off all weeds, afterwards treating the other half in a similar manner, and finally spreading the Onions evenly over the whole area. This is far better than leaving them amongst weeds and rubbish, which hold the dews and moisture and prevent a free circulation of air amongst the bulbs. The thick-necked and otherwise deformed portion of the crop should be placed by itself and used first, being quite useless for keeping. When hoed the best shaped bulbs if wanted for seed should be strung on ropes in the old-fashioned way and suspended from the roof of some cool, dry shed or outhouse, a little frost benefiting rather than injuring them. Occasionally on wet days the stock should be examined in order that any decaying bulbs may be removed.

**THINNING SPINACH.**—The plants resulting from the early August sowing of winter Spinach are now forward enough for thinning. Caution must, however, be exercised in the matter, as wireworm will sometimes attack the roots between now and the final thinning stage. A distance of a foot at least ought to be left between each plant, especially if occupying warm borders where growth is likely to be soft and rapid. When sown on more exposed quarters, and not too thickly, less thinning is necessary, as the foliage is not so tender and easily affected by frost and wet. Although lime and soot were dug in when the ground was being prepared, I would strongly recommend a good surface sprinkling of the latter immediately thinning is completed, mixing with it a little fish manure or other approved fertiliser; this, with a thorough stirring with the Dutch hoe, will give the crop a good start, and certainly a much better chance of resisting grub and canker attacks. Secondary sowings should be watched, and cleaned if necessary, as soon as the growth peeps through the ground, this crop repaying any labour bestowed on it, its value in winter being so very great. I have this autumn again sown a bed of the summer Spinach, as I last year found it to be as hardy as the prickly, and certainly more crisp and juicy. Slugs are often very troublesome on heavy land in showery weather, and will soon ruin a large breadth if unnoticed. A sprinkling of lime and soot occasionally as a preventive rather than as a cure is best. Where this vegetable is much esteemed and any more vacant plots occur, seed may yet be sown with every prospect of a free growth, the produce coming in most useful at the new year. For these extra late sowings, however, a sunny border is to be preferred; sow in very shallow drills in order to secure a quick germination.

**CAULIFLOWERS.**—The autumn section of these will now demand attention. On hot dry soils this season Autumn Giant has a very blue appearance, owing to insufficiency of water at the roots. This condition not only induces attacks of caterpillars and other insects, but small, badly coloured and shaped heads, the same being ready for cutting long before they are wanted. To prevent this give the roots at once a good watering with liquid manure, repeating it in a couple or three days' time. It is astonishing how quickly this will alter the appearance of the plants. If growing on borders easily reached, a good drenching overhead with the garden engine will assist in cleansing all filth from the leaves and centres, largely benefiting the roots also. The next matter needing attention is retarding the swelling of the heads and preserving the colour, this being best done by tying up the leaves over them; and if it is feared that the supply will not last out till the required date, lift the plants with as much soil as possible and lay in on a cool, moist north border, allowing a little room between each for a free circulation of air. Walcheren growing between rows of Celery may, if the soil is wanted for earthing up, be lifted in the same way and laid in also. Self-protecting Autumn is invaluable for following close on the heels of Autumn Giant, and, besides being well shielded by the interior folding leaves, comes in more piecemeal than Autumn Giant and will keep for a good time in a cool place if lifted. With care, heads of this useful Broccoli may be

had up to the time Backhouse's Winter White is ready for cutting, this now being preferred by me to Snow's, as it is hardier and more easily obtained true.

**EARLY CELERY.**—In most places, even where extra early Celery is not desired, slight earthing up will now be necessary. Fortunately, the Celery maggot is less troublesome this season than usual and the ground is strong and clean. Where, however, this pest is present, even in small numbers, hand-picking must be practised previous to earthing up, as sometimes even after this date it will spread alarmingly. If Celery is expected in the dining-room in October, the earliest rows of Sandringham White or Early Rose should now receive the final banking up, and if rain has very lately fallen, the sooner this is done the better, as then the moisture will be shut in and benefit the roots. When the soil is being brought up to the stems it is always best for one man to grasp the stick firmly with both hands to prevent dirt getting in amongst them, but when through scarcity of labour ties have to be used, they should either consist of soft matting, which will yield to the pressure of the advancing swelling, or if of twine the ties should be afterwards cut. By this time later rows of Celery will need a little attention, suckers having in some cases grown out from the base. These must all be removed as well as weeds and a good drenching of farmyard manure administered. By no means earth up Celery in a very dry condition, or tough stringy growth and much running to seed will follow. Where any spare plants were put out on flat ground to be grown for flavouring, a channel should be formed by drawing up a good portion of soil on either side, this acting as a reservoir when water is applied.

**CELERICAC.**—This is a critical time for this little-grown, but most useful vegetable, as if at all dry at the roots a check is given to growth, and toughness and inferior quality result. In order to avoid this, adopt the same plan as recommended for the late Celery, namely, that of forming a channel for the reception of water. Of course where planted in shallow trenches, as it really ought always to be, the roots have a much better chance.

**CARDOONS.**—The earliest rows of these will now be ready for partial earthing up. Tie clean hay bands closely round the stems, afterwards banking the soil against them somewhat thickly. Cardoons are particularly thirsty subjects, and therefore need an almost unlimited supply of stimulating liquid at this particular date.

**MUSTARD AND CRESS.**—As the nights become colder and the days shorter these may be sown in boxes and placed in a perfectly cool house, sowing weekly.

J. CRAWFORD.

### FERNS.

#### SOWING SPORES.

EARLY in the spring is undoubtedly the best time for sowing spores of the choicer and more delicate Ferns, yet good results may often be obtained by sowing at any other season. It is only when a very limited supply of spores is to be had that I should confine the sowing to the spring months. In the first place there is often so much other work to attend to at that season that they are apt to get neglected, while late in the autumn there is a good opportunity of giving every attention to collecting and sowing spores. The collecting of the spores is by no means an unimportant matter. In the first place, the plants from which the spores are to be collected should be kept by themselves as much as possible. Any of the choicer sorts should never be allowed to come into contact with those which germinate freely and which often prove troublesome weeds. I may mention *Neprodium molle*, *Pteris cretica*, and some of the *Gymnogrammas*, especially *Martensii*, as being among the most troublesome.

*Pteris tremula*, though when sown by itself is sometimes difficult to get to maturity, will often spring up and choke the choicer sorts. The best time to take the fronds for spores is as soon as the spore cases show the first sign of bursting. In some instances the spores drop out and are lost almost before they appear to be matured. *Osmunda palustris* is an example of this, and *Pteris argyrea* must be closely watched, or all the best spores will be lost. There is a great difference in the colour of perfect spores. In the *Osmunda* referred to above they are quite green, and in *Pteris argyrea* they are black. Most of the *Davallias* have yellow spores, and in the *Platycerium* they are brown.

The best spores are undoubtedly those collected from plants which have been grown in a light and rather dry position. Summer and autumn are the best seasons for collecting them. It is not always from those which appear the most prolific that the greatest number of seedlings is obtained. As an example of this I may mention the *Onychium*. In *O. auratum* what appear to be good spores are produced in immense quantities, but it is very rarely we get a good batch of seedlings; while in japonicum seedlings spring up freely where the spores are hardly visible. I could give other instances of similar character.

One of the most difficult problems in Fern culture is to account for the appearance of something quite different from that which has been sown. I have known instances of certain Ferns making their appearance which have hitherto been unknown. A few years ago, when some of the choicer sorts of *Adiantum* were sown, I had quite a large batch of *Microlepia platyphylla* spring up among them, though previously I had not grown it. I have several times known *Pteris tremula* to come up thickly when *Lomaria gibba* has been sown, though the spores sown were saved from plants isolated from the tremula. I can quite understand the difficulty in getting any variety true when the spores are saved from a mixed collection, but seeing the number of Ferns we raise which do come true (I have known many instances where there has been hardly a stray weed among a good batch), it is difficult to account for the appearance of the quantities of strangers in other instances where the spores have been saved with equal care and sown under exactly the same conditions. I may mention with reference to this that on one occasion spores of some varieties saved in the nursery were sown, and as they were abortive, nothing whatever germinated in the pots, while at the same time spores which were collected by a gentleman in New Zealand, Ceylon and Java were sown, and though nothing new was obtained, we had a big crop of crested *Pterises*, *P. tremula*, *Gymnogrammas* and others, including various crested forms. Although it is often contended that Fern spores will retain their vitality for a number of years, and instances of this have been proved, yet newly-collected spores are more reliable and should always be used if it is possible to get them.

A. HENSLEY.

**Frost and insect pests.**—The old idea that a sharp winter destroys a great number of insects has, I think, almost exploded. At any rate, what I have seen during the past week convinces me that there is not an atom of truth in it. In many cottage gardens in Middlesex and Herts it has been difficult to preserve anything in the shape of a plant from the ravages of slugs, snails, caterpillars, and earwigs. The foliage of Sunflowers in particular has been riddled to such an extent as to mar the appearance of the plants. In some

of the market gardens also large quantities of soot had to be sown immediately the Coleworts were planted out, or the crop would have been ruined, owing to the large colonies of slugs and underground grubs. Earwigs have been a veritable plague in many private gardens this summer. Peaches, Nectarines, Apricots, and in fact all kinds of fruit have been much riddled by them. The same may be said of kitchen garden crops, Cabbages, Globe Artichokes, and Lettuces having in some instances been almost devoured. Much trouble is also being caused amongst *Chrysanthemums* by these pests, and those who grow Dahlias for exhibition have to be constantly on the look out. I think sharp winters come much harder on the feathered tribe than on insects, as such delicate birds as robins, hedge sparrows, and wrens have not appeared in their usual numbers this summer, many doubtless having died during January and February.—J. C.

## STOVE AND GREENHOUSE.

### LILIUM SPECIOSUM AND ITS VARIETIES IN POTS.

ALTHOUGH of late years the larger and more showy *Lilium auratum* and its varieties have taken the first place amongst Japanese Lilies with the majority of growers, I have never been able to give way to the prevailing taste, for I consider the much older species to be superior to it in many respects. In the first place it is more easily grown. *Lilium auratum* is so capricious that most persons are obliged to treat it almost as an annual. Of course, there are some highly favoured localities, such as the late Mr. McIntosh's at Duneevan and Mr. G. F. Wilson's at Oakwood, where this difficulty is not encountered, but by the generality of growers, whether in the open or in pots, the same complaint is made—"We cannot keep it." This is not the case with *Lilium speciosum*. It can only be through carelessness or ignorance that the bulbs of this are lost. The second point in which I think the superiority is on the side of the older Lily is in the gracefulness both of the flower and plant. Another point I think is the perfume. The very strong scent of *auratum* and its varieties is most objectionable to many people. It has not indeed the offensive odour which some Lilies have, though it has that peculiar heavy perfume which precludes it very much from use for indoor decoration. But there is a delicacy about the scent of lancifolium and its varieties which makes them grateful even in a room. I have often noticed at some of our exhibitions how people give a wide berth to *auratum*, and where there are many of them they make the whole atmosphere very heavy. It is now about fifty years since I first became acquainted with *Lilium speciosum*, or, as it was then known, lancifolium; it had only been lately introduced. Since then I have ever grown it and sometimes under most disadvantageous circumstances, and I have seen during that period a considerable development in the beauty of the flowers, while the increase of the number of bulbs grown all over the country has been enormous, and, like *auratum*, it can be now had for a mere trifle. Not only are enormous quantities imported from Japan, but those wonderful cultivators of bulbous plants—the Dutch—have been raising it from seed scales, so that the number has been greatly increased. There is, however, one result, that a large number of varieties has been put into commerce, and these, like all seedlings, vary so very much, that if you order either roseum or rubrum you may get something different from what you expected. Many of them

are pale and washy and consequently of little value, while, on the other hand, varieties of most decided merit have been obtained and these have been sent out under specific names. If the amount of colour in some seedlings is so small as to make them comparatively worthless, there are others which by the brilliancy of their colouring are very attractive. Of course, all persons may not have the same ideas on this subject, but I much prefer the more highly-coloured varieties. After having grown, I believe, all of the varieties, I must give the palm to—

**LILIUM SPECIOSUM MELPOMENE.**—This is stated to have been of American origin, but whether from seeds or from bulbs imported from Japan I am unable to say. The ground colour is a rich rose, profusely spotted over with bright carmine spots, the edges of the petals having a line of white. It is not at all improbable, from what I have experienced, that other varieties are often sent instead of this in execution of orders. I used formerly to consider it somewhat of a poor grower, but that is not the case now, as my plants of it are as vigorous as any that I have.

**L. S. SUPERBUM** is, I think, one of the most satisfactory of the highly-coloured varieties when you can get a good strain of it. I have had it from various sources; the habit of the plant is excellent, and I can only wish that I could give it more room than I am able to do in my small house. The colouring is very beautiful, approaching closely to that of Melpomene, and, altogether, the plant is a most pleasing one.

There are several white varieties, and all of these are very chaste and beautiful; the finest of all is one that I have received from Holland, under the name of

**L. SPECIOSUM VESTAL.** The petals are larger and the colour if possible purer than in any other variety, and the habit of the plant is all that can be desired. I have not as yet seen this tribe in the open ground, but I should think a group of it would be very beautiful. Next I think in beauty comes

**L. S. KRETZERI**, pure, clear alabaster-white, with broad petals without any tinge of green in them. This, too, is a good grower, with fine foliage. The older variety,

**L. S. ALBUM**, must, I think, give way to these newer and purer varieties.

**L. S. MACRANTHUM** is another of the highly-coloured varieties; the flowers (as its name implies) are large, and although they are not equal in intensity of colouring to those of Melpomene and superbum, they will, I think, rank next to them in size and brightness.

**L. S. PUNCTATUM** is a peculiar form; the spots are very pale, and I have always found it a difficult one to keep, but I should imagine, from the low price at which it is quoted, that this is not the general experience of growers.

There are a number of other varieties, such as purpuratum, atro-purpureum, Schrymakersi, corymbiflorum and corymbiflorum monstrosum, but many of these differ more in their style of growth, and I think that those that I have mentioned are the best worth growing.

**LILIUM HENRYI.**—I now come to a somewhat difficult question, on which I must touch with great diffidence. There has of late years been introduced a most beautiful Lily from Northern China, and when it has been wished to describe it people say that it is an orange-yellow speciosum. Is this literally true, or is it only a fanciful description? I am no botanist, and, therefore, possibly I am plunging into a quagmire, but it does strike me that this very beautiful Lily is the same as speciosum, with a variation of colour, caused, it may be, by climatic influence. At any rate it is a most beautiful Lily, and it is just possible that when hybridisers get to work we may have some beautiful crosses between this and speciosum, although it will not be well to indulge in too sanguine hopes upon this point,

for no really successful hybridisation has taken place with auratum since its introduction. I think we must regard the American *Lilium Parkmanni* as a failure, inasmuch as it has never been put into commerce, nor from what I hear is it ever likely to be. Lovers of Lilies will, however, cheerfully welcome this new addition as a most distinct and beautiful one.

I have said nothing about the culture of this beautiful class of Lilies, but in truth it is of the simplest character. I pot mine in the late autumn in a compost of leaf-mould, loam, some well-rotted manure, and sand. I occasionally use some peat, but as the leaf-mould which I use is very old it partakes very nearly of the character of peat. When potted I place the pots in cocoa-nut fibre or ashes under a glass covering, but exposed fully to the air. If the weather be severe I cover up the pots with ashes. In the spring I bring them out and put them under a still more open glass roof, and as they come into bloom I bring them into the greenhouse, where at this time of the year they are very attractive. I am careful neither to cut off the stems prematurely after they have done flowering nor to allow the pots to be soaked by the heavy autumn rains.

DELTA.

## CANNAS.

GROWN in former years for the sake of their foliage, Cannas have gradually come to the front as flowering plants. Twenty years ago the blooms were insignificant and the plants ran up high, so that they were but little grown in pots. During the last few years so much progress has been made, that Cannas are now among the best things that can be grown for conservatory decoration during the summer and early autumn months. The size of the flowers has been much increased; they exhibit considerable diversity of colour, and this improvement in the blooms is accompanied by a much dwarfed growth, so that well-flowered plants can be had in 7-inch pots. Probably these dwarf Cannas would be much more cultivated by owners of small glass houses if their merits were more widely known. In large establishments they are now much in favour both for indoor and open air decoration. A great point in their favour is the remarkable ease with which they may be cultivated. As regards the amount of labour and expense involved in their culture, they are among the most economical of plants that are grown under glass. In this respect they resemble tuberous Begonias, for from November till March they can be stored away under stages of cool houses or in a cellar, needing scarcely any attention. Compare this simple way of keeping through the winter with the constant care involved in preserving the ordinary run of flowering plants at that time of year, and the true value of Cannas will easily be recognised. Plants that have been grown in pots can remain in them through the winter in any frost-proof place, giving no water from the time the foliage dies off. Just as growth commences they should be shaken out and divided, repotting in good loam, with a rather liberal addition of well-rotted manure or some concentrated stimulant. If required to bloom early in the summer they must be looked to in February, in which case it is safer to wait till signs of growth are being made before disturbing them. In a temperature of from 55° to 60° they will soon move, and can then be divided if so desired. It is better to wait until growth has begun before dividing,

especially in the case of new or choice kinds, as otherwise there is some danger of the fleshy roots decaying. If a quantity of plants is required, propagation may be effected in the same way as is pursued with Dahlias, the roots being placed in warmth early in February, if possible on bottom heat, and the young shoots taken off with a bit of heel when about 2 inches long. They strike with great freedom in a temperature of 65°, and very quickly if the cutting pots are plunged in fermenting material and get bottom heat in some way. Where plants in 6-inch and 7-inch pots are required, it is necessary to then propagate annually, and of the dwarf growing forms one

*Rheum Emodi.* (See page 199.)

may have nice well-flowered specimens about 2 feet or even less in height, which are of much use for table or room decoration through the summer months. Cannas are gross feeders, and from the time the roots touch the sides of the pots liquid manure should be given twice a week, otherwise the flowers are liable to be under-sized and not so numerous as they should be. When plants with several flower-stems suitable for grouping at exhibitions are required, it is better to strike the cuttings in small pots so as to avoid root-disturbance when repotting. If the cuttings are inserted as soon as they can be had, they will eventually come into 8-inch pots, forming handsome bushy specimens that are telling when grouped with Palms, Ferns, and other things. Few things are more effective when planted out for the summer months than Cannas, and if the plants are strong when set out and the season is fairly fine, the grower may enjoy the beauty of the flowers as well as that of the foliage. When requiring a large quantity of them for this purpose I used to store the roots in a cellar, putting them in closely on a hotbed early in February, inserting the cuttings singly in small pots and plunging them in fermenting material. They quickly formed roots and were then removed to a moderately heated house and shifted into 4½-inch pots, using a rich compost. Later on they

underwent the usual hardening process and were set out early in June in rich soil. In this way they went off into free growth. In those days the varieties ran up tall, making strong leaf growth, but the flowers were too small and few in number to create any appreciable effect. The only aim of raisers at that time was to obtain highly-coloured foliage and reduce the height. Fine as many of the newer kinds are, they are probably nothing to what is to come. Raisers are only beginning to realise what can be made of the Canna from a flowering point of view. Some of the newer varieties, such as Aurora, Duchess of York and Diavolo, are, however, so fine, that one might think that the maximum of size of bloom has at least been reached. Improvement will, however, undoubtedly continue, and we shall probably in time to come see Cannas with flowers rivalling in size, and perhaps brilliancy, those of the Gladiolus. Among those having dark-coloured foliage, Geoffery St. Hilaire, M. André, President Faure and President Carnot are very good, and of the green-leaved kinds, Madame Crozy, very dwarf and brilliant in colour; Jules Chrétien, Baron Sandroms, Chevalier Besson and Madame Just are good and distinct. These are, however, only a few of a great number of fine kinds all worthy of good culture. J. C.

*Biflect.*

## TREE CARNATIONS.

SEVERAL times I have been asked to define the difference between Tree and border Carnations. As there are some varieties which are intermediate between the two types, it is a little difficult to draw the line. The term "Tree" has been applied to all those which keep up a succession of bloom, though some are quite dwarf in habit. Most of the older varieties were tall growers, and branched out freely all up the stems. I may give White Swan, Laura, Sir Charles Wilson, and Andalusia as good types, while the Old Crimson Clove, Gloire de Nancy, Mary Morris, Alice Ayres, and Mrs. Reynolds-Hole are types of border varieties. In these, even when grown in pots, the lateral branches are confined to the base of the plants, and it is rarely that these side shoots flower the same season as the main shoot, while in those belonging to the Tree section, even those of dwarf growth, the lateral shoots follow on, and in some instances keep up a succession of bloom when planted out. Winter Cheer is a good example of this. I noticed this particularly at Messrs. Veitch's Chelsea nursery about two years ago. It was planted out, and began to bloom at about the same time as the border varieties, and continued long after all the others—in fact late in November it was flowering and had plenty of buds to follow. Though few are so free as the above, I have known others to throw up successive flower-stems four and five times in a year. The seedling plant of Henry Gibbons flowered five times within a year. Miss Joliffe is another example of this type.

Pride of Penshurst is sometimes included with Tree Carnations, but it certainly belongs more to the border kinds. Though it is more inclined to flower from the laterals the first year than many varieties, it will also succeed better in warmth, and by propagating from cuttings early in the spring the same plants will flower the following autumn. By growing on separate batches of plants it is not impossible to have flowers of this throughout the winter. Germania is much less inclined to flower from the laterals the same year, though it will bloom well in the autumn if strong plants are potted on in the spring and the first flowering stems taken out as soon as they begin to run up.

I have tried a good many border varieties for winter flowering, or rather early spring flowering in pots, but have always found the flower-stems run up long and weakly compared with those of the Tree type. None of the Carnations will stand much forcing, and I believe failure often occurs through giving too much heat and not enough air during the winter. Plenty of light, air and sufficient heat to keep out frost are the chief essentials, and though over-watering must always be avoided, it is very damaging to go to the other excess, for if Carnations once get very dry in the pots when in bud the flowers will not open perfectly; it is necessary to be careful.

Winter-flowering Carnations may be grown in the open during the summer, but should be protected from heavy rains and taken indoors early in the autumn. It is important that the plants should be kept free from insects. Although there may be no appearance of any when the plants are taken indoors I should recommend the use of the fumigator, as this will check the small thrips which are almost invisible to the naked eye, though terribly destructive to the blooms. The white specks on the blooms, which some are puzzled to account for, are a sure indication of these destructive little insects. The little maggot, which of late years has been a great source of trouble to Carnation growers, must also be looked after. Frequent use of soot water will go a great way towards keeping off the fly which breeds this maggot, but when it once gets into the plants it is only by catching it before it gets buried too deeply in the stems that the plants can be saved.

A. HEMSLEY.

## FRUIT AND VEGETABLE CROPS.

### NORTHERN.

**Hurworth Grange, Darlington.**—Strawberries this season have been especially good. All kinds of Currants are good, but red are hanging badly, owing to the constant wet weather we have had during the two last weeks in July and first two weeks in August. Raspberries were also poor from the same cause. Apples are a heavy crop. While Pears are thin, Peaches in case an excellent crop and of good size, but require sun. Apricots are a complete failure. The trees were well set with bloom, but the frosts we had during February killed every bud. Plums are very irregular. While some trees are already breaking down with the weight, a great many trees are not carrying a single fruit. This appears to bear out the remarks made in my report last autumn, that so many trees suffered from the May frosts in 1894 and had to break again, consequently had not time to ripen and bring the buds to maturity, as the trees that were sheltered and escaped the damage are the trees that are carrying the crops. We have had abundance of rain (nearly 6 inches in July) and fruit has swelled pretty well. As a rule fruit is late, and the late varieties will require a fine autumn, or they will not ripen.

Early Potatoes were good, but in the second earlies I am finding a few touched with disease. Peas have been and are still good; in fact all vegetables are pretty satisfactory.—JOSEPH SIMPSON.

**Calderstone, Allerton.**—The hard frost of the past winter did little harm here. The only things that suffered were Raspberries and two varieties of Strawberries, namely Laxton's Latest of All and Aberdeen Favourite. The latter I have looked upon as one of the hardiest, but I am discarding it this season. The Strawberry crop here has been an excellent one. John Ruskin has

done well and is a handsome fruit. Scarlet Queen is still better and has cropped abundantly. Those who have not grown it would do well to give it a trial. It promises to be a strong rival to our old friend Vicomtesse H. de Thury. Last year I thought Laxton's Latest of All the best late variety. This year Waterloo has been much better and lasted longer. Dr. Hogg if planted in a slightly shady position is nearly as late as any and much better flavoured, if not of the brightest colour. Other fruit crops have been good, Apricots excepted. Apples are a good crop and some time has been spent in thinning, which I think is labour well spent. Pears are a fair crop. Cherries of all kinds are most abundant. Peaches and Nectarines, Red, White, and Black Currants, also Gooseberries have been abundant.

Vegetables look well and seemed to do well with the dry weather. Those who have not grown Veitch's Climbing French Bean should do so. I think it will be found that the Scarlet Runner will not be so much grown, as the former is of better flavour and does not require such tall stakes. Sorry to find the Potato disease has made its appearance in the late Potato crop.—W. TUNNINGTON.

**Grimston Park, Yorkshire.**—Apples are not a full crop this year: Lord Sutfield, Keswick Codlin, Cockpit, Warner's King, Lewis' Incomparable, Yorkshire Greening and Copmanthorpe Crab have good crops. The fruit promises to be fine in size, but not in colour. If I were planting either Apple, Pear or Plum trees for commercial purposes I should without hesitation plant those on low worked stocks, allowing each kind of Apple to form its naturally shaped head, in no case permitting them to exceed from 10 feet to 12 feet in height. Trees of the former are much more under control than standard trees are, and, other things being equal, will give much better returns. Apricots are a good half crop, fruit fine, but not well coloured, owing to the dull wet weather of the past month. Kaisha and Hemskirk are the most free cropping Apricots, but the fruit is small and not good in flavour. Moorpark and St. Ambrose are the best of the early fruiting kinds. Cherries are a fine crop, especially Morellos, which is the main kind I grow. Sweet Cherries, excepting May Duke, never fruit well here. As mentioned in previous notes I find pyramidal-shaped bushes of Morello Cherries give quite as good crops as the same kind when grown on north walls. Peaches are a very nice crop, the trees clean and healthy. I picked the first dish of ripe fruit on August 10; the kind was Hale's Early, which with me is a good cropper on walls. It is fully a week earlier than another useful wall Peach, viz., Condor. Nectarines do not succeed so well with me as Peaches; the fruit almost invariably cracks just before ripening. I find it an advantage to lift the roots of outdoor Peach trees every two years. Pears are not quite an average crop, Marie Louise and Jargonelle being the only two sorts which have good crops amongst some twenty kinds, excepting the very early kinds, such as Doyenné d'Ete and Citron des Carnes, which always give good crops. Plums are not a full crop, excepting Victoria; on walls they are very thin as a whole. Jefferson, Kirke's, Orleans and Green Gage are the best kinds of the choicer Plums hereabouts, and they must be grown on walls to succeed. We have a thin crop of Damsons in an orchard grown as standards. It may be of interest to mention these trees are growing in an alluvial soil which is only just above the water line during the winter, when the adjacent land is often flooded by the overflowing water from the river Wharfe. For several years the trees were healthy, but never fruited. About eight years ago, after a heavy flood, it was decided to give the whole orchard a good dressing of land lime. The season but one afterwards I had a splendid crop of fine Damsons. Needless to say I have since given two other dressings of lime, though not quite so heavy. Some five miles from here there are large orchards of Winesour Plum trees; it is at Sherburn-in-Elmet. The soil is a loamy

one overlying the carboniferous limestone. The fruit from these orchards is much noted for its fine flavour when preserved, and generally fetches a good price. The trees are mostly on standards, and one of the largest growers tells me he always propagates his stock from suckers of old fruiting trees, never from seed. The main points as to culture are an occasional thinning out of branches in the winter, being careful not to overdo this, or the trees are a year or two before they fruit well again. The soil underneath the trees is laid down in Grass, a dressing of manure being given occasionally when the trees are established and bearing well. Small fruits have been abundant and fine. Strawberries were a splendid crop. La Grosse Sucrée, Noble, Héricart de Thury, Keens' Seedling, Anguste Nicaise, President and Newton Seedling are the kinds I have. Raspberries were very good, especially Superlative. Walnuts are very plentiful: Hazel Nuts fairly so. Mulberries not so well cropped as last year.—HENRY J. CLAYTON.

**Chillingham Gardens, Belford, Northumberland.**—The fruit crops in this neighbourhood on the whole are very good this season. We have had splendid crops of Strawberries, Gooseberries, Red, White and Black Currants. Raspberries are a heavy crop and very large, also dessert Cherries and Morellos. Apples are a very heavy crop. Pears are not so good. Peaches light and Apricots few, as most of the spurs and a good many branches were killed by the severe winter. This is not a great Plum locality; still Victoria, Early Prolific, Prince of Wales, Cox's Emperor and Prince Englebert have good crops.

The soil is a good strong loam, but we suffer much from early and late frosts. We had 5° in June, and a cold wind which cut down Potatoes, Scarlet Runners and French Beans to the ground.—R. HENDERSON.

**Thorpe Perrow, Bedale, Yorks.**—The Apple crop is fairly good, some kinds being heavily laden. Pears are much the same, early sorts carrying the best crops. Plums with us are not good, our heavy clay soil does not suit them. On some parts of this estate Plums do well on a limestone bottom and bear enormous crops. Bush fruits were plentiful, especially Red and White Currants. Black Currants suffered from the very severe frost in the winter, so did some of the tender sorts of Gooseberries; many of the latter were quite killed. Strawberries were abundant everywhere in this northern part of Yorkshire. Apricots are very scarce. The spurs were much injured by the frost; in some exposed places they were quite killed.—WILLIAM CULVERWELL.

**Naworth Castle, Carlisle.**—Apples are above the average. Apricots and Pears good. Cherries, both sweet and Morello, a fair crop. Strawberries a very heavy crop, but the fruit small. Gooseberries and Red and White Currants are above the average, while Black Currants are very poor. Raspberries are a poor crop, half the canes having been killed by the severe frost last winter. Plums are a light crop, Green Gage and Victoria being the best.

Early Potatoes have been small, but late varieties look better than I have seen them for the past two seasons. All the Brassica tribe is very backward in this district. Onions and Carrots are good and free from maggot. French Beans and Scarlet Runners are good, but they received a severe check on June 13 and 15, when we had 3° and 5° of frost respectively.—A. E. SETTON.

**Eshwood Hall, Durham.**—The Strawberry crop has been an excellent one, both with regard to quantity and flavour of the fruit. The varieties I have found the most suitable here are Vicomtesse Héricart de Thury (which stands foremost as a sure cropper), President, and Laxton's Noble. Raspberries, Currants, and Gooseberries have never been more plentiful than they are this year with me, which, I think, is pretty general in this district. Apples are a fair average crop; they would have been an excellent crop but for the long-continued drought. Growers who took the precaution to mulch their trees well in

the early part of the season will have seen the advantage of it now. Pears are a moderate crop, but on the whole as good as we can expect in this northern climate. The same remark applies to Plums. Cherries are a good crop, but this season they have excelled themselves, as I have never in the North seen finer crops.—A. BENTLEY.

**Chetwynd Park, Newport, Salop.**—The fruit crops here taken altogether and in the district generally are very good. The only failure is Apricots, but I believe they bore a very heavy crop last year and there were no flower-buds formed. Apples are very abundant, and are looking clean and healthy. Pears a fair crop, but nothing like last year, the better varieties being thin. Plums a good crop, and Damsons are heavily laden. Bush fruits have all been abundant, and Strawberries an enormous crop. Cherries are thin, with the exception of Morellos, which are a heavy crop. Here we have a light and sandy soil on gravel. Stone fruits are consequently more uncertain, especially in dry seasons. The best flavoured Plums are Reine Claude du Bavay, Green Gage, Kirke's and Jefferson.

The vegetables suffered much in the early part of the summer. Cauliflowers were only half a crop, many being lost. Onions are not so good this year, being much troubled with the maggot. Potatoes have been, and are, very good, and late ones, with the acceptable rain we have had, are looking very promising.—N. SHERWOOD.

**Worsley Gardens.**—The few Plum and Damson trees we have are carrying the best crop I have seen here. All varieties of early Apples are a full crop of good quality; later varieties are good in quality, but a thin crop. All trees are healthy and good, having quite recovered from the disastrous effects of last year. Pears are a good crop all round. All small fruits, Strawberries, Raspberries, Currants, and Gooseberries have been plentiful and of capital quality. In consequence of the dry hot weather we had little succession of Strawberries; all came in together.

During the dry weather it was difficult to keep vegetable crops alive, but we have now an abundant growth. Potatoes up to the present are coming out clean and good, but I notice an attack of disease in the foliage, which must be favoured by this damp close weather. The past winter, severe as it was, has done very little damage beyond completely checking every bit of vegetable. The winds that prevailed during the past dealt roughly with many evergreens, but they made a speedy and complete recovery.—W. B. UELONS.

**Castle Howard.**—With the exception of the excessive cold at the beginning of the year, the weather has been most favourable to the fruit crops. Towards the end of May rain was needed, and it came on June 1 in sufficient quantity to get to the roots of most things; therefore the yield of fruit has been, and is, abnormally large. Apricots, however, are scarce, but the enormous crops of last year may have as much to do with the comparative failure as the long-continued and severe frost of the early part of this. Apples are plentiful, and the individual fruits promise to be large and reach maturity early. Pears are under the average, but of good size. Plums are the heaviest crop I have seen in this neighbourhood, especially Rivers' Early, Victoria, Gages, and Damsons. Cherries have been a fine crop of well-developed fruit. Peaches and Nectarines an average yield, Hale's Early Peach being exceptionally fine. Apricots almost a failure, in some places quite so. Gooseberries have been an enormous crop, and dessert varieties of excellent quality. The same remarks apply to Raspberries. Red Currants a good average yield, but Black rather thin on the bushes. Nuts an average crop. Strawberries have been an abnormally heavy crop, the fruit large and of excellent flavour.—J. RIDDELL.

**Elmet Hall, Leeds.** Apples average crop, fruit fine, especially Lord Suffield. Pears in some cases heavy crops, Jargonelle and Winter Nelis

with us are the best. I have seen trees of Jargonelle in the district covered with fruit and of fine quality. Cherries have dropped their fruit very much in the dry weather, although some Morellos have a fair average crop. Plums, of which Victoria is the most popular, are very irregular, some trees having more fruit than the branches are able to support, while others adjoining have none. There are not many grown about here, as they appear very uncertain owing to late spring frosts. Kirke's and Jefferson we esteem the best for flavour. Black Currants below the average, but Red and White very heavy crops of fine clean fruit. Gooseberries have probably never been better, both as regards quantity and quality,

*Rheum officinale* in flower. (See p. 199.)

Whinham's Industry especially so. Strawberries and Raspberries have been abundant and large; of the former I find Vicomtesse H. de Thury and President most prolific. The soil here is a strong clay, and by deep cultivation and early mulching we do not suffer so much from drought. The late thunder-storms have damaged the fruit very much, causing many to rot, while Gooseberries are bursting from the excessive rains and continued damp, rain having fallen on twenty-one days, with a total of 5.82 inches for July.

Vegetable crops are very good, Peas especially, of which we always depend on No Plus Ultra for general and late crops; nothing better for flavour, and can be had in succession by timely sowings

until frost comes. Potatoes are sound and good, free from disease up to time of writing. Carrots are the only failure; every year they succumb to the grub. This year we filled the drills, after sowing, with charred refuse from the rubbish heap, and have given dressings of nitrate of soda, but with no better results, and sown on fresh trenched land, too. Probably the soil may be too cold and stiff for them.—THOS. BONSALE.

**Anderley, Kirkby Lonsdale.**—I consider 1895 a good average season; the fruit trees of all descriptions wintered well and the drought did not affect us. Amongst Apples, Keswick Codlin, King of the Pippins, Fearn's, Stirling Castle, Ecklinville, Lord Suffield, Hawthorden, Annie Elizabeth, and Northern Greening are noticeable for heavy crops. Pears are well represented by Marie Louise, Louise Bonne of Jersey, Doyenné du Comice, and Winter Nelis. Only Victoria Plum bears freely with us. Kirke's on walls does well, but in this cold district we do not get many sets to fruit. Damsons bear well in the immediate neighbourhood. Bush fruits have borne magnificently—Gooseberries Whinham's Industry and Warrington bearing heavily. Strawberries have been excellent, reminding one of the crops and flavour of more southern climes. Dr. Hogg is a fine cropper; John Ruskin does well. Our soil is a light one and gravelly, so we get our finest fruit off the forced plants that were planted the previous season.

Vegetables are looking well. Peas want sunshine. No Plus Ultra is 5 feet high and not in flower. Webb's Senator is a fine second early. Early Potatoes were cut down on June 15, so rather a lighter crop than usual, but grand in flavour, particularly Sharpe's Victor. Late Potatoes are promising and no appearance of disease yet. The Bruce and Windsor Castle are favourite field kinds.—W. A. MILLER.

**Hummersknott, Darlington.**—The following may be taken as indicative of the fruit crop in our immediate locality: Apricots a failure. Apples and Pears average. Plums above average on standards. Strawberries, Raspberries, Gooseberries, and Currants other than Black are an abundant crop. Black Currants under average.—J. SHORT.

**Windlestone Hall, Ferry Hill.**—The fruit crop in this neighbourhood is very good. Apples a grand crop. Pears on walls good, in the open a medium crop, the bloom having been damaged by cold, biting winds. Apricots an average crop; Hemskirk by far the best. Plums on walls carrying heavy crops; in the open many dropped owing to the long drought. Those most in favour here are Jefferson, Bryanston Green Gage, Transparent Gage, and Kirke's. Strawberries were an immense crop, but owing to the dry season rather small. On the light soil here Black Prince does well and is earlier than Noble. Currants, both Black and Red, are plentiful, and Gooseberries are a very heavy crop. Raspberries also good, but are being spoiled by repeated heavy rains. The heavy rains will be of immense benefit

to orchard trees and those under walls, which, in spite of repeated waterings, were very dry.—C. G. BAILEY.

**Birdsall, York.**—In this district, with a few exceptions, the fruit crops are good. Apples average crop. Apricots none on wall, abundance in Apricot shed without front lights. In this structure the fruit and wood get ripened early, a great advantage in every way. Peaches on walls a nice crop; the unripe wood of the trees was killed by the severe frost of the past winter. They are now looking healthy and well. Plums average crop. Pears under average, some varieties on wall good. Cherries (dessert and Morello) abundant. Strawberries over average and excellent in

quality. Raspberries, Gooseberries, Red and Black Currants abundant and good. Very little damage done to fruit trees by the late frosts, and we were favoured with heavy showers of rain in this locality during the time the Strawberries were in bloom.—B. WADDS.

**SOCIETIES AND EXHIBITIONS.**

**ROYAL HORTICULTURAL SOCIETY.**

SEPTEMBER 10 AND 11.

THE chief features at this gathering were the displays of vegetables both in the conservatory and the large marquee. In the former were arranged the non-competitive exhibits by the trade and private growers, prominent amongst which was the magnificent display made by Messrs. Sutton and Sons, Reading, notably the Tomatoes in great variety—these were grand examples of culture—the huge Onions, and those two standard Potatoes, Satisfaction and Windsor Castle. Opposite these were choice assortments of various vegetables of the best strains from Messrs. J. Veitch and Sons, whilst lower down were other admirable collections from Syon Gardens, Mr. Wythes, as usual preferring the best table qualities to mere size, and from Messrs. R. Veitch and Son, of Exeter. Another most noteworthy display was that made by Sir Trevor Lawrence, Mr. Bain thus making a new departure. The special features here were the dishes of vegetables of sorts not frequently seen, as well as the standard of quality as opposed to that of mere size. From the Royal Gardens, Frogmore, Mr. O. Thomas sent a most admirable display, arranged with excellent taste as a trophy; here again it was quality that predominated in preference to size. In the competitive part of the exhibition there was a tendency on the whole to stage overgrown examples rather than those of the very best quality. This applied to Beetroot, to Cauliflowers, and other every-day kinds of vegetable. The collections of vegetables were arranged with good effect, so also was the premier collection of salading in twenty-four varieties from Syon Gardens—a most tasteful display in a round basket.

Of flowers the Dahlia held undoubted sway, notably in the Cactus and the single sections, a few decided novelties being found amongst the former. In this flower a new departure was made by an arrangement of Dahlias to show their suitability to purposes of indoor decoration in the home. Miss Hudson, of Gunnersbury House, is credited with this exhibit. Reference should also be made to the most instructive collection of Roses staged in bunches from Waltham Cross, whence Messrs. W. Paul and Son had sent a selection of the best autumnal bloomers, chiefly Teas and Chinas.

Orchids were in point of numbers quite a minor portion of the show, the entire exhibit of plants being easily counted upon the fingers. In spite of this, however, a few charming hybrids were exhibited from Messrs. Veitch's collection.

**Orchid Committee.**

On this occasion only one first-class certificate was awarded, but no plant could hardly be more worthy of it than

**LÆLIO-CATTLEYA CLONIA SUPERBA** (*Lælia elegans* Turneri × *Cattleya Warscewiczii*), which is quite a gem amongst hybrids. The contour of the flowers is that of *C. Warscewiczii*, but with the upper sepal shortened, the petals being broad in comparison to the sepals; the colouring partakes greatly after that found in *Lælia elegans* Turneri (itself the best of its type), a deep rosy pink with darker veins, the substance partaking greatly of the same parent, whilst the lip in its expanded form pointed most decidedly to *Cattleya Warscewiczii*; this was of full size and lightly fringed with a wavy outline, the colour being a bright purplish crimson, altogether a most notable hybrid and one of evidently free growth. From Messrs. J. Veitch and Sons.

Awards of merit were made to—

**LÆLIO-CATTLEYA EUNOMIA** (*C. Gaskelliana* × *L. pumila* Dayana), in which the growth was quite intermediate, the outline of the flowers, however, inclining towards the last-named parent, but much larger: the sepals and petals were of a darker tint than in *C. Gaskelliana*, with the lip also darker, but not so much so as in *L. pumila* Dayana. In point of size it was intermediate, the throat having a prominent blotch of old gold. From Messrs. J. Veitch and Sons.

**LÆLIO-CATTLEYA PARYSATIS** (*L. pumila* × *C. Bowringiana*).—This is a much dwarfier hybrid than the preceding, having evidently in this respect been more influenced by *Lælia pumila*. The flowers are about the size of those of *C. Bowringiana*, but the colour is a bright rosy pink in the sepals and petals, whilst the throat is quite light, thus contrasting all the more with the purplish rose of the lip. From Messrs. J. Veitch and Sons.

**CYPRIPEDIUM CARNUSIANUM** (Veitch's var.) (*C. Haynaldianum* × *C. Spicerianum*).—The latter parent is to be seen in the form of the dorsal sepal, which in point of colour is, however, much deeper, being of a deep purplish flush with the base spotted, this latter characteristic being also clearly defined in the petals, which are spotted with purplish bronze on a light ground, the extremities being nearly all purple. The lip is of a bronzy tint. The plant bore two flowers on the one spike, the fully developed one having the lower sepal divided, forming, as it were, two wings. From Messrs. J. Veitch and Sons.

From the same source came also a lovely example of *Lælio-Cattleya Nysa purpurea* (*C. Warscewiczii* × *L. crispata*), in which the very conspicuous lip had assumed more of the purple as seen in *L. crispata*, whilst the sepals and petals partook of its other parent. *Cypripedium Metis* (*C. philippense* × *C. Boxalli*) was also included. This has the growth and dorsal sepal of the latter, with more of the form of the petals imparted by the former parent and its smaller lip. *C. Boxalli atratum* Lawrenceanum, another form, was also included.

A botanical certificate was awarded to *Maxillaria striata*, a distinct species with the sepals and petals of old gold with crimson lines, the lip being white with purplish lines. From the Botanic Gardens, Glasnevin. Mr. Cummings brought from Mr. Smee's collection at The Grange, Carshalton, a fine form of *Cattleya Hardyana*, the lip very conspicuous, well defined and of deep colour, the spike bearing three flowers.

**Floral Committee.**

Awards of merit were granted to the following:—

**DAHLIA (POMPON) CLARIBEL**.—A fancy variety with neat flowers, the florets white, tipped and flushed with purple. It was shown by Messrs. C. Turner and Sons, Slough.

**DAHLIA (POMPON) ZOE**.—The flowers of this kind are of a rich yellow shade, the florets tipped with white in a distinct and attractive way. From Messrs. C. Turner and Sons.

**DAHLIA (POMPON) GANYMEDE**.—This is of a novel shade of orange-buff, flushed with mauve-pink on the edges of the florets. From Messrs. C. Turner and Sons.

**DAHLIA (POMPON) MADELEINE**.—Another of the fancy kinds, pale yellow edged with rose. Also shown by Messrs. C. Turner and Sons.

**DAHLIA WILLIE BACHELOR**.—This has flowers about the size of those of the pompon varieties, but with the long reflexed florets as seen in the larger decorative varieties, and striped with scarlet and white. It was shown by Mr. Batchelor, Harefield Park, Uxbridge.

**DAHLIA (SINGLE) MRS. GORE LANGTON**.—A distinct and fine-flowered variety of a purplish crimson shade, with a rich zone of maroon-crimson at the base of the petals. Also from Mr. Batchelor.

**DAHLIA (POMPON) ROSEBUD**.—This pretty kind, with flowers of a clear rosy pink shade, was shown by Messrs. J. Cheal and Sons, Crawley.

**DAHLIA (CACTUS) MRS. WILSON NOBLE**.—The flowers of this are of the best Cactus form and charming in colour, which is a clear, soft cerise or salmon-red. From Messrs. J. Cheal and Sons.

**DAHLIA (CACTUS) MISS A. JONES**.—A bright rich scarlet self of brilliant effect, and shown by Mr. J. T. West, Tower Hill, Brentwood.

**DAHLIA (CACTUS) MISS NIGHTINGALE**.—This has fine flowers of a distinct bronzy red, shading to orange-yellow at the base of the florets. Also from Mr. West.

**PHLOX LEONARDO DA VINCI**.—One of the herbaceous varieties, its flowers white, with a prominent eye of carmine-red. It was shown by Messrs. Barr and Sons.

**SUNFLOWER STOKE PARK FAVOURITE**.—Another form of the annual Sunflower, its flowers of medium size, having broad, rich yellow rays and a black disc. It was shown by Mr. J. Hughes, Stoke Park Gardens, Guildford.

Messrs. W. Paul and Son, of Waltham Cross, made a fine display of autumn Roses, showing a large and comprehensive lot of the very best autumn-blooming sorts, in which Teas and Monthlies were a prominent feature. Among Teas, Marie van Heutte, Mme. Hoste, G. Nabonnand, Mme. Chedane Guinoisseau, Ethel Brownlew and Sylphe (their new pink variety) were all admirably represented by large bunches of fresh flowers. In Monthlies, Duke of York was shown in great quantity; Mme. Laurette Messimy was charming, and Queen Mab, a new kind, well shown, is certainly a noteworthy addition to this class and most distinct in its rich shade of orange-buff flushed with pink. La France, Mrs. J. Laing, Marie Baumann, Lerna Doone, Captain Christy, Ulrich Brunner and Eclair were also shown in good bunches, and several Polyantha varieties. Altogether the group was a first-rate representation of the Rose beauty so easily obtainable, yet so conspicuously absent from gardens at this season. A silver Flora medal was awarded. A similar award went to Messrs. Barr for a large and varied group of the best hardy and annual flowers now blooming. Phloxes were fine, especially Bayardère, a pure white self, and Liberté, salmon-rose. Pyrethrums, Heleniums, Helianthus, Echinops Ritro, early Michaelmas Daisies, with Sweet Peas, Verbenas, Phlox Drummondii, Balsams and Antirrhinums were all features in the group. Dahlias in show, fancy, and Cactus varieties were very well shown by Mr. S. Mortimer, of Farnham, whilst Messrs. J. Cheal and Sons made a great display, also chiefly with Cactus, pompon and single-flowered sorts. A silver Flora medal was awarded to both groups. Mr. T. S. Ware exhibited a grand bank of all the best Cactus Dahlias, with pompons in bright colours massed in the foreground. A silver-gilt Banksian medal was awarded. Messrs. C. Turner and Sons and Mr. J. T. West also showed a number of new pompon and Cactus Dahlias in addition to those to which awards of merit were made. Mr. Salmon, West Norwood, received a silver Banksian medal for a group of Zinnias, African and French Marigolds, China Asters, Salpiglossis, Dianthus, Phlox Drummondii, and other annual flowers. A similar award was given to Mr. Anthony Waterer for a group of five fine seedling plants of the blue Colorado Spruce (*Abies pungenis argentea*), the plants charming in colour and perfect health. Miss Hudson, of Gunnersbury, made a large exhibit of cut Dahlias, in pompon, Cactus, and single varieties, arranged in large vases, epergnes, and baskets, with a few Grasses and Asparagus growths, showing well that even Dahlias can be arranged artistically and pleasing for house or room decoration. A silver Banksian medal was awarded to this instructive exhibit. From the Earl of Ducie, Tertworth Court, Gloucester, came branches of *Quercus Kellogie*, a distinct Oak with large leaves deeply cut into sharply pointed lobes, and *Q. lobata*, a variety having a small narrow leaf with the lobes regularly rounded.

**Fruit Committee.**

A first class certificate was given to:—  
**MELON THE EARL'S FAVOURITE**.—A green fleshed fruit of medium size, richly flavoured, and

above the average of new seedlings; this was given an award of merit last autumn, and was now given the higher award. From Mr. Ward, Longford Castle Gardens, Salisbury.

Awards of merit were given to:—

**APPLE REMBROUGH.**—A very heavy, nice-looking cooking variety, much like Alfriston in shape, but very firm and of a dark bronze colour on the sunny side. It is a heavy cropper and in season early in the year. From Mr. Cummins, The Gardens, The Grange, Hackbridge, Wallington.

**FRENCH BEAN NORTHUMBERLAND PROLIFIC.**—A very free-cropping, early variety, with large, long broad pods almost equal in size to those of Canadian Wonder, but much earlier. It is a cross between Mohawk and Ne Plus Ultra. From Mr. G. Wythes, Syon House, Brentford.

**RUNNER BEAN SUTTON'S A 1.**—Sent out by Messrs. Sutton in 1891. It has been on trial at Chiswick this season. It is a very fine variety, noted for size, flavour, and cropping. From Messrs. Sutton and Sons, Reading.

The following Potatoes, having been on trial at Chiswick and received three marks, were given awards of merit:—

**POTATO SYON HOUSE PROLIFIC.**—A handsome variety, with rough skin and shallow eyes. It is most prolific and free of disease. It is a cross between Sutton's Seedling and an unnamed variety. From Mr. G. Wythes.

**POTATO COKERELL'S SEEDLING.**—A white-fleshed round of good quality, a heavy cropper and of excellent quality.

**POTATO PRIDE OF TONBRIDGE.**—A flattened round, nearly fluke shaped, rough skin, white flesh, very few eyes, and heavy cropper.

**POTATO TRIUMPH.**—A well-known main crop variety with rough skin. It is a heavy cropper of splendid quality. From Messrs. Sutton and Sons, Reading.

**POTATO BIRMINGHAM.**—A white-fleshed variety of good quality.

Awards of merit were given to Cabbages Early York, Sutton's Little Gem, Leed's Market Red, Early Erfurt, Winnigstadt, St. John's Day, and Savoy Petit Trise d'Aire.

Messrs. Spooner, Hounslow, showed a fine collection of Apples, notable being Keswick Codlin, Lord Sutfield, Yellow Ingestie, and Alfriston (silver Knightian medal). Messrs. Bunyard sent fine Lady Sudeley Apples, and Messrs. Rivers Marshall's Seedling and very fine Cox's Orange Apples. Mr. Horne, Rochester, showed a very nice-looking seedling Apple, and Mr. Hudson choice alpine Strawberries. From Mr. Webster, Gordon Castle, N.B., came two seedling Plums of great merit, but too ripe. Mr. Miller, Esher, and Mr. Corbett, Mulgrave Castle, Whithy, sent seedling Melons. Messrs. Cheal, Crawley, had some very pretty varieties of Crabs.

#### Vegetable Show.

For the best twelve dishes of vegetables, distinct kinds, there were five exhibitors, these collections forming a special feature of the show. Mr. T. Wilkins was first with a grand lot, Giant Cauliflower, Lyon Leek, Goldfinder Potato, Autocrat Pea, Perfection Tomato, and Globe Artichokes very fine. Mr. Bowerman, Hackwood Park Gardens, Basingstoke, was a close second. For nine dishes, Mr. Waite, Glenhurst, Esher, Surrey, was first with very fine Carrots, Solid White Celery, Satisfaction Potato, Snowball Turnip, Autumn Mammoth Cauliflower, &c.; second, Mr. W. T. Empson, Amptill. For six dishes the quality fell off somewhat, and there was less competition, Mr. Kneller, Basingstoke, being first, with good Carrots, Onions, Celery, Tomatoes, and Windsor Castle Potatoes. For three Cauliflowers there were eight competitors, Mr. Empson being first. In the class for Scotch Kales, Mr. G. Wythes was first with fine heads, Mr. Pentney, Worton Hall, Isleworth, being second. Mr. Bowerman was first for Brussels Sprouts, having very solid Dwarf Gem. There was only one lot of Spinach, Mr. Empson being first with Victoria of good quality. Vegetable Marrows were well shown, Messrs. Mairs, Lye,

and Wythes taking the awards. Messrs. Lye and Waite had the best Cucumbers in order named. For Scorzoneria, Messrs. Pentney and Osman were the successful exhibitors. For Runner Beans, Mr. Lye was first and Mr. Bowerman second. Dwarf Beans were equally numerous and good, Canadian Wonder being chiefly shown, Messrs. Bowerman, Wythes and Ward taking the awards. Broad Beans were scarce, the season being past. Mr. Lye had fine Laxton's Alderman, Mr. Bowerman being a good second with a Windsor variety. For Peas there were eight entries, the varieties staged being Autocrat, Ne Plus Ultra and Dwarf Mammoth, Messrs. Palmer, Ward and Wythes taking the awards in order named. For Globe Artichokes, Mr. Wilkins was first and Mr. Empson second. For Cardoons only one lot was staged by Mr. Wythes, who had very fine heads. Potatoes were largely shown, but much too coarse. Mr. Pope was first in the three kidney varieties, with Magnet, Matchless and White Kidney. For rounds, Mr. Pope was again first with Satisfaction, Perfection and Nonsuch. Mr. Lye had the best single dish of kidneys. Leeks were not numerous, but good for the season. Mr. Lye was first with Prizetaker; second, Mr. Mairs. For Onions Mr. Waite first, and Mr. Mairs second. Turnips were plentiful, Messrs. North and Osman taking the prizes for the three varieties, all white roots being staged. For single dishes, Messrs. Waite and Lye had very good Snowball varieties. For Celery, Mr. Wythes was first, with good solid roots. The class for Carrots was very strong and all good, Messrs. North and Pope taking the awards for the three varieties, Messrs. Mairs and Wilkins for the single dish. Parsnips were equally fine, Mr. Lye being first with Student. For Beet, Mr. Webster, Beckenham, was first, and Mr. Waite second. There were some very fine heads of Celery, Messrs. Wilkins and Waite taking the awards. For the best collection of salading, Mr. Wythes was a good first, staging twenty-four varieties, Tomatoes in a growing state being trained over the basket, all the small salads and the Celery being beautifully blanched. For the best pot and sweet herbs, Mr. Salmon, West Norwood, was a good first. For any other vegetable, Mr. Waite staged Tomatoes.

In the large vinery was staged by Messrs. Veitch a very extensive collection of vegetables, all the new and really good vegetables and salads being represented (silver-gilt Knightian medal). The same remarks apply to a grand collection of vegetables shown by Messrs. Sutton and Sons. Here were probably the finest dishes of Potatoes and Onions ever staged. The collection included fifteen varieties of very fine Potatoes, Ailsa Craig Onions, Prizetaker Leek, Cabbages, &c. (silver-gilt Knightian medal). From the Royal Gardens, Frogmore, was staged a large quantity of vegetables of all kinds tastefully arranged. (silver-gilt Knightian medal). A very good collection of vegetables was sent by Mr. Wythes from Syon House, Brentford, some sixty varieties being staged, including a dozen plants of Tomatoes in pots of the leading kinds (silver-gilt Knightian medal). A collection which was much noticed was made up of small varieties, rarely exhibited, including scarce herbs, various kinds of Aubergines, Capsicums, Indian Corn, Japan and China Marrows, also various small Gourds, Haricot Beans, Soakale, Cabbage, and Tomatoes from Mr. Bain, Barford Lodge, Dorking (silver-gilt Knightian medal). A very fine collection of Onions, Leeks, Carrots, Savoys, and other vegetables was staged by the Messrs. Cannell, Swanley (silver Knightian medal). Messrs. R. Veitch and Son, Exeter, staged very fine Tomatoes Flying Dutchman, Potatoes (Red Beauty being very good), Leeks, Carrots, Beet in variety, and Cauliflowers (silver Knightian medal). Messrs. Barr and Sons staged a most meritorious collection of Kales and thirty varieties of Tomatoes, including some kinds rarely seen, but remarkable for their good quality. The fruit was of a nice size, none being too coarse (silver Banksian medal). Messrs. Fellowes and Ryder, Orpington, staged a very fine lot of Duke of York Tomato, remarkable for their clear skin, smooth

ness and good quality (silver Banksian medal). Messrs. Dobbie, Rothesay, had a small, but remarkably good collection, the varieties shown being Champion Leek, Parsnips, Tomatoes, Celery and Parsley (bronze Banksian medal). Mr. Ward, Richmond, was given a bronze medal for a large dish of Chemin Tomatoes grown in the open, the fruits being very fine. A nice collection of seven varieties of Peas with Lettuces sent by Mr. Hudson, received a cultural award. A similar award was given to Mr. Wilkins for fruits of the Mango from Inwood House, Dorset. Mr. Empson, Amptill House Gardens, Bedford, had some new Carrots of very fine quality. Mr. Woodward, Isleworth, sent good market Cabbage in quantity with Brussels Sprouts and Turnips. Mr. Powell, Weybridge, sent a huge Gourd. Mr. Wythes had very good Veitch's Autumn Protecting Broccoli, and Mr. Jones, Hanger Hill, Ealing, had a large stand of Mushroom spawn.

The lecture on manures was read by the assistant-secretary in the absence of Mr. W. G. Watson. The first place, as a manure for garden crops, was given to farmyard manure, which was found to contain all the essential elements of plant food, both organic and inorganic, and its varied composition made it by far the most perfect manure. The best method of treating it, so as to secure its maximum amount of plant-feeding constituents, was fully detailed, and the great source of loss pointed out when manure was allowed to lie in heaps and become fermented, its volatile elements escaping into the air and liquids allowed to drain off also. The manure made under covered yards was better, because there was less saturation by rain and evaporation. The temperature of the heap should never be allowed to rise above 150° F., and if there was any danger of this happening, the heap should be cooled down with water. As regards its application, the fresher the manure the less ready it was as a plant food, but in proportion to the extent to which it was well made, the more promptly could its fertilising ingredients be turned to immediate use. But although a perfect manure as far as it went, most cultivators were now agreed as to the necessity of other manurial aids which contained fewer elements in concentrated form, so that phosphates or nitrates could be applied more efficiently to growing crops that required one or the other in greater amount. The several manures now in general use were passed in review, and their nature and constituents briefly mentioned. The value of lime was particularly stated and enlarged upon, especially as a factor that more than anything else assists in breaking up or pulverising clay lands, whilst even light soils retained moisture better by its use upon them. A very interesting discussion followed. Mr. Odell explained an admirable system that he had seen of dealing with sewage, of which there was often much available at a time when gardeners had no use for it. This difficulty had been admirably met with in the instance quoted by passing it through a series of pits filled with leaves, so that all its elements became available for use in a solid way much preferable to using the liquid. Gas-lime, a plant poison badly used, he had found was also salvation to the Brassica tribe if rightly used, as upon ground dressed with it they enjoyed an absolute immunity from clubbing and its attendant evils. Mr. H. W. Ward, of Longford Castle, said he had found it advisable to use artificial manures for vegetable crops, especially Potatoes, which were not nearly so susceptible to disease as when grown in ground rich with fermented manures. In all his garden crops he got a cleaner and better produce.

Mr. Bunyard agreed with these remarks and also advocated Rape dust, which was much used in Kent. It was the residuum after the extract of the oil and was left in a hard cake, but if broken up into pieces about the size of a Walnut and mixed with an equal quantity of soil, there was no better manure for root crops, and it was an admirable stimulant to give to Asparagus just as it was commencing to grow in spring. An additional advantage in favour of its use was its cheapness.

## THE NATIONAL DAHLIA SOCIETY.

The annual exhibition of this society was held at the Crystal Palace on September 6 and 7, and the gathering was a good representative one of all classes of this flower. The entries were somewhat less in number and the competition, especially among amateurs, not quite so keen as it has been on previous occasions. Some of this is due to the extremes of weather that have prevailed during the present season, as evinced also by the fact that one or two noted growers complained of their Dahlias being in a backward state and flowers not yet up to show form, whilst others who had them more advanced said the hot dry days that preceded the show had proved very trying and made it difficult to preserve that freshness of the flowers which adds so much to their effect on the show table. Some of the oldest kinds among the show flowers still maintain their high position, as, for example, James Cocker, of which many magnificent flowers were shown; indeed, it was rarely absent from the prize-winning stands. It is a deep purple self. Mrs. Gladstone also was conspicuous throughout the show, always easily distinguished because of its soft and lovely blush shade of self colour. Besides many fine blooms in the collections there were no less than seven stands of this kind in the class for six blooms of any light coloured Dahlia. The feature of the show, however, and one which appeals to and gratifies lovers of flowers generally, was the growing numbers and exceeding beauty of the Cactus-flowered section which now embraces a wider range of more brilliant colours with many tender shades. The society rightly encourages them, as doubtless through this class a fresh impetus will be given to Dahlia culture in gardens.

## SHOW AND FANCY DAHLIAS.

The best sixty blooms of these in the largest class of the show again came from that noted grower, Mr. Charles Turner, Royal Nursery, Slough. The exhibit was a good one, but the flowers generally were more irregular in size and finish than is usually the case. The finest were George Rawlings, Mrs. Langtry, Arthur Ocock, Chieftain, Penelope, Gloire de Lyon, a massive white self, J. T. West, Grand Sultan, James Cocker, Maid Fellows, J. T. Rawlings, Diadem, David Sanders, Earl of Ravensworth, Pleasance, W. Garratt, Goldfinder, Mrs. Gladstone, Prince Bismarck, John Walker, and Shottesham Hero. Mr. John Walker, of Thame, was second with a nice lot, and Messrs. Keynes, Williams, and Co., Salisbury, third. The next class for forty-eight blooms, distinct, embraced the same varieties as are enumerated above, and Messrs. Turner, Walter, and Keynes, Williams, and Co. were successful in the order named. For thirty-six blooms, distinct, Mr. G. Humphries, of Chippenham, was an admirable first, showing a very regular and massive lot of flowers. The best were Queen of the Belgians, Glow-worm, Ethel Britton, Mrs. Gladstone, Duke of Fife, and Duchess of York. Mr. J. T. West, Tower Hill, Brentwood, was second, and Messrs. Saltmarsh, of Chelmsford, third. For twenty-four blooms, distinct, Messrs. Saltmarsh were first, Mr. West second, and Mr. G. Humphries third. The best twelve blooms in the low and fancy section came from Messrs. J. Cheal and Sons, Crawley, fine flowers of Mrs. Gladstone, W. Rawlings, G. Rawlings, Arthur Ocock, and John Walker being shown. Mr. Arthur Rawlings, of Romford, was second, and Mr. H. Harris, Chelmsford, third.

In the amateurs' classes of this section, Mr. Thomas Hobbs, of Easton, Bristol, showed well, curing first honours for twenty-four distinct blooms—Mrs. Gladstone, Earl of Ravensworth, Harry Turner, T. W. Girdlestone, Prince of Denmark, and Duchess of York, all very fine. Mr. Swkes, Castle Bromwich, Birmingham, was second, and Mr. Anstiss, Brill, Bucks, was third. For twelve distinct blooms of show varieties only Mr. Starling (gardener to Mr. H. H. Raphael, Liverpool, Essex) was first, and Mr. J. Gurney Fowler, South Woodford, Essex, second. Mr. C. Jeffries, Chippenham, had the best six distinct

blooms, Captain Lowe, Fresfield, Isle of Wight, being second. For twelve blooms of fancy varieties only, Mr. Anstiss was first, and Mr. S. Cooper, Chippenham, second; whilst for six of the same class the prizes went to Mr. A. Starling and Mr. Jeffries in the order named. The best six blooms of any dark Dahlia came from Mr. Charles Turner, who showed grand flowers of William Keith, Mr. Mortimer, of Farnham, being second with James Cocker. Mr. J. Walker was first for six of any light Dahlia, showing fine flowers of a white self that bears his own name. Mr. Mortimer was second with Mrs. Gladstone. The best six flowers of a yellow variety also came from Mr. J. Walker, who showed William Powell; and Mr. Mortimer was second with John Hickling. For six tipped blooms, Mr. F. W. Seale, of Sevenoaks, was first, showing Mrs. Saunders, a yellow, tipped with white, and a charming stand of blooms. Mr. Mortimer was again second. Mr. Humphries showed the best six blooms of any striped variety in Frank Pearce, Mr. J. Walker being second with Matthew Campbell. Mr. Walker was first for the best six edged blooms, Mr. J. T. West being second.

## CACTUS AND DECORATIVE DAHLIAS.

In the open class for eighteen varieties in bunches, six blooms of each, Messrs. J. Cheal and Sons were an admirable first for an exhibit of even character, the flowers delightfully fresh. They showed Purple Prince, Beauty of Wilts, orange-red; Mr. Barnes, salmon and yellow; Matchless, dark maroon; Kaiserin, rich yellow; Professor Baldwin, scarlet; Mrs. Wilson Noble, salmon-red; Delicata, rose-pink, with white centre; May Pictor, buff, shading to yellow; Mrs. Gordon Sloane, deep red; Countess of Gosford, orange buff; Bertha Mawley, rich crimson; Mrs. H. Cannell, orange; Lady Penzance, yellow; and Earl of Pembroke, deep purple. Messrs. Keynes, Williams and Co. were second, and Mr. Charles Turner third. The best twelve varieties, six in a bunch, were shown by Messrs. J. Burrell and Co., of Cambridge, their finest being Gloriosa, Major Haskins, Harmony, Robert Cannell, Earl of Pembroke, Countess of Gosford, and Mrs. Peart. Mr. J. T. West was second, and Mr. F. W. Seale third. The decorative varieties now receive less attention since the improvement and increase of the Cactus-flowered forms. Messrs. J. Cheal and Sons were first for twelve varieties in bunches of six blooms, Messrs. Keynes, Williams and Co. being second. In the amateur classes, Mr. J. Stredwick, Silverhill, St. Leonards-on-Sea, showed well, and secured first for twelve varieties, six blooms of each, the sorts similar to those that have already been enumerated. Mr. Brown, gardener to Mr. W. Morris, Oak Lodge, Horley, Surrey, was second. For six distinct kinds, Mr. E. Mawley, Rosebank, Berkhamsted, was first with a charming lot, Mr. S. Cooper, being second. For nine varieties of Cactus Dahlias Mr. J. Stredwick again came to the fore with a fine lot, Mr. Brown, Oak Lodge, being second. For four bunches of Cactus kinds sent out by Messrs. H. Cannell and Sons, Mr. W. Mist, Ightham, Sevenoaks, was the only exhibitor, and received first prize.

## POMPON AND SINGLE DAHLIAS.

These were shown finely by Messrs. Turner, who were easily first for twenty-four varieties in bunches of ten blooms of each. The best were Nerissa, rose; Diana, pale yellow; Fabio, scarlet, shading to orange; Arthur West, dark crimson; Bacchus, bright red; Purity, white; Ganymede, rosy buff; Amber, deep yellow; and Captain Boyton, dark crimson. Messrs. Keynes, Williams and Co. were second, and Mr. F. W. Seale third. For twelve varieties Messrs. J. Burrell & Co. were first, their exhibit containing fine bunches of G. Brinckman, white; Emily Hopper, deep yellow; H. E. Searle, orange-red; and Red Indian, deep crimson. The second prize went to Mr. J. T. West and the third to Mr. G. Humphries. In the amateurs' classes for pompoms, Mr. J. Hudson, Gunnersbury House Gardens, was first for six

bunches, ten blooms of each. This was a neat and pretty lot, the varieties Mars, crimson; Golden Gem, rich yellow; Favourite, maroon; Apollo, light buff, with Leila and Eric, two fancy kinds. Mr. J. Stredwick was second. For six varieties in bunches of six blooms Mr. S. Cooper was first and Mr. G. Wyatt (gardener to Mr. G. Hilditch, Twickenham) was second. Messrs. J. Cheal and Sons showed the best twenty-four varieties of single Dahlias, in bunches of ten blooms of each, the finest being The Bride, white; Marion Head, rose, with white centre; Duke of York, orange-crimson; Miss Roberts, yellow; Demon, dark maroon; and Miss Henshaw, pale yellow. The second lot came from Mr. F. W. Seale. In the amateurs' class for six varieties Mr. T. W. Girdlestone, Sunningdale, Berks, won the first prize with a pretty lot, comprising Prince of Wales, crimson, shading to maroon; Golden Locks, yellow; Gold Dust, scarlet suffused with yellow; Kitty, blush and white; Dearest, a lovely kind variegated with transparent white and canary-yellow; and Soubrette, a bizarre flower of several shades. Mr. E. Mawley was first and Mr. W. Parrot, Sevenoaks, second in a smaller class. Fancy single Dahlias were shown by Messrs. Cheal and Seale, who were first and second in the order named.

Among new Dahlias, Yellow Globe, deep yellow; Hero, light orange-red; and Sepoy, dark maroon, were all fine flowers of the show type, exhibited by Mr. Harris, Seads Hill House, Orpington. Florence Tranter, blush, edged with purple, was shown by Mr. Tranter, Henley-on-Thames. Cactus varieties were numerous. Mrs. Stirling, crimson; James Hudson, deep orange-red; Mrs. Wilson Noble, salmon-red, a lovely shade of colour; Mrs. Montefiore, rich crimson, all came from Messrs. Cheal. Nil Desperandum, bronze-yellow, and Harry Stredwick, maroon-crimson, were shown by Mr. J. Stredwick, whilst Mr. Hudson showed a single-flowered Cactus kind named Adeline. Messrs. Pope, of Birmingham, sent flowers of a double crimson Cactus form named Ida Pope, whilst a yellow one named Marquis of Salisbury came from Mr. Grist, Freshwater, Isle of Wight. Messrs. Turner showed a fine stand of blooms of their new variety named Beatrice, which is of a most distinct rosy mauve colour.

The miscellaneous exhibits were large and good. Mr. T. S. Ware made another great display of Dahlias, boldly, though somewhat formally arranged, whilst Messrs. Dobbie and Co. made a large exhibit of Dahlias. Messrs. Cannell and Peed showed Dahlias and other flowers, Mr. M. Prichard a large group of hardy flowers, and Messrs. Laing, of Forest Hill, two fine groups, one of Gloxinias and the other of Caladiums.

## MR. A. F. BARRON.

TO THE EDITOR OF THE GARDEN.

SIR,—As a Fellow of the Royal Horticultural Society of England, I claim the right of saying with what extreme surprise and regret I read the ambiguous and weak-kneed apology of the council in your last issue. As an explanation it is lamentably weak and unsatisfactory. The secretary's apology also obscures the main point of this affair by introducing details as to retiring allowance and testimonial, &c., about which we are all or nearly all agreed. The main point at issue is this: Granted that the council had every right to place their Chiswick superintendent on the retired list, did they proceed in the matter in an honest, straightforward manner? The general impression abroad is that they did not so proceed, but that they went about the business in a way suggestive of a secret conspiracy. It is the general belief (despite the frank expression of regret) that some mean and undignified methods were resorted to, and this feeling it is the business of the council to allay. Not only has the council ignored the Chiswick board, but it has caused a feeling

of deep distrust to spring up as to the future business of the society. What guarantee have the Fellows that matters will not again be mismanaged? Some of us would like to know if the present president and council really do their best for the society, or whether they allow the secretary to do as he likes. Let us have the whole truth of the miserable affair and done with it. Let us have the report and correspondence for what it is worth at once. As a matter of fact the council have either brought about the retirement of the Chiswick superintendent in a proper manner or they have not done so, and the best way of dispelling doubt and erroneous inferences will be to publish at once the whole of the correspondence and the actual report as signed. This is a plain duty the council owe not only to their own Fellows, but to every gardener in the British Islands as well. Not to produce the direct evidence asked for will of course only defer the matter until the next annual meeting. As it is, everyone interested is asking all sorts of questions about the unbusinesslike manner in which the affair was conducted. Surely it is not necessary for such a society to resort to any secret methods of procedure! The Royal Horticultural Society of England should be above suspicion, but at the present moment it is not in that desirable position, for there is suspicion in many minds as to the present and also doubts as to the future.

It is no use the council ordering the secretary to write plausible apologies that satisfy no one, but only intensify the spirit of distrust. Let the report and its attendant correspondence be published; that is really the best way to dispel misapprehension as to any unfairness or discourtesy.—F. R. H. S.

—The letter of the council of the Royal Horticultural Society which appeared in your issue of the 7th inst. is plausible, but eminently unsatisfactory. The apology contained in the letter to the Chiswick Board is particularly feeble, but this does not much concern the Fellows, inasmuch as that body is the council's own creation. However, to say the least of it, the excuse in the letter is very extraordinary; not consulting the child "was due to an oversight," a thing hardly possible to have happened in a body of intelligent men. I am more inclined to the idea that it was not to the interest of the promoters of the "special committee" to consult the Chiswick Board, and as a Fellow I accept the excuse with a grain of salt. The Fellows have now to consider how far the honour of the society is involved in the secrecy of the council in appointing "a special committee to advise them as to the future of the gardens" when they had a standing committee for, I presume, the very purpose of advising them on all matters connected with the gardens, and if it was not doing its duty the council should have dissolved it, and then appointed a committee to answer the object they had in view; this would have had the virtue of being straightforward, but as the council has taken a tortuous action, they must also take the consequence of having created a feeling of uneasiness in the minds of many Fellows, which justifies the suspicion that there is a want of fair play generally. The treatment of their child was un-English; that to Mr. Barron was full of ingratitude and unhandsome. As to the remark of the council's "intention to promote a testimonial to Mr. Barron," it was well for the success of the testimonial and the credit of the council they did retire, as their action would only have been viewed as a "blind." Is there no chance of the Fellows bringing the council to see what valuable services they are sacrificing or induce them to produce the report which led up to Mr. Barron's virtual dismissal? We now know the names of the men who signed the report, and the council would consult their reputation by making this report public. If the council will not

take action, I trust that one or other of "the special committee" will have the courage to make the facts known. Murder will out, and as there is no legal restraint, I feel sure there can be no moral one in such a case. One conclusion we may safely draw if the council still refuse to produce the report, is that it is clear the report is wanting in backbone, and what is hid under the cloak of the "special committee" would prove more damaging to the council's reputation than it could be to that of Mr. Barron. If the council fail to consult their reputation, then the Fellows must take action and appoint a committee of investigation, and this should be done promptly, as the advertisement is out for a new superintendent "possessing practical and scientific knowledge of all departments of horticulture." As a Fellow, I should wish to know if the council have made themselves severally and individually responsible for the pension of £180 voted for Mr. Barron, or how do they propose to raise the sum annually? as assuredly there will be a falling off in the subscriptions of those who look upon Mr. Barron's dismissal as a job. Then, again, the reference in the council's letter to "the desirability of making considerable changes in the gardens at Chiswick" might not be approved of by the Fellows—a not at all unlikely thing. This would lead to a further falling off in revenue. The new superintendent is to have £200, a salary which, added to the pension, makes a total of £380, as against £225 paid to the present superintendent, who possesses in an eminent degree the qualities the council are advertising for, viz., "practical and scientific knowledge of horticulture"; indeed, few men equal Mr. Barron in the knowledge that relates to horticultural science and practice. A correspondent signing himself "Lux," and who evidently can throw some light on the finances of the R.H.S., writing in a contemporary says, "the resources of the R.H.S. are limited." If so, where is the pension to Mr. A. F. Barron to come from, seeing this will entail an extra sum of £155 per annum? "Lux" evidently writes with knowledge, and may not be unwilling to answer this important question. There are wealthy men on the council; have they the courage of their convictions to guarantee the society's revenue to the extent of its expenditure, or the amount of the pension to Mr. A. F. Barron should the society be unable to pay him annually? If the wealthy members of council are not prepared to guarantee Mr. Barron his pension, why get rid of him, considering he is the most capable man who has ever had charge of Chiswick Gardens, and who has still ten good years' work in him. Mr. Barron has in the past met all the requirements of the most exacting councils, and I fear not he could fulfil all that the present council could get out of any other man, and especially an untried man. The risk is great, and the council must be told they will be held responsible for the results arising from any forced change. If the council are really consulting the interests of the Fellows of the R.H.S. and the advancement of horticulture, they would take the Fellows into their confidence, lay their plans before them, get their adherence and support, and should the change referred to not prove a success, the Fellows, having been partners to it, would not be unreasonable; but if a few men take so much responsibility upon themselves, no consideration must be made for their failures or their follies.—PETER BARR.

**The weather in West Herts.**—Another hot week and the fourth unseasonably warm week in succession. On one day the highest shade temperature reached 78° and on another 79°. On only one occasion has the latter temperature been exceeded in September during the previous ten years, and that was on September 11, 1891, when the shade maximum was 81°. Some of the nights were particularly warm, and on that preceding the 6th the thermometer exposed on the lawn never fell lower than 56°, which is an unusually high minimum reading for the month. On Tuesday

last the temperature of the ground at 2 feet deep stood at 64°, and at 1 foot deep at 66°. The latter reading is about 7° in excess of the September average for that depth. Only insignificant amounts of rain have fallen during the last fortnight, except on the 6th inst., when about three-quarters of an inch of rain fell. This was during a rather severe thunderstorm. About 4 a.m. there occurred an exceptionally heavy downpour, exactly a quarter of an inch of rain falling in ten minutes. Since the beginning of the month the sun has shone brightly, on an average for 7½ hours a day, which is a splendid record for the early part of September.—E. M., *Berkhamsted*.

**Roses failing.**—I am in a difficulty with my Rose house. I put in a good border of clay, manure, and old loam, which I planted with Teas, and up the roof I have climbers, but this is the second year in which I have failed to get any decent flowers. The buds are small and the plants look sickly, the leaves turning yellow and falling off. Can you tell me what is the cause? I have top ventilators and also box ventilators built into the walls.—W. R. F.

\*\* We do not see how you could possibly have treated your Roses better as regards soil and the formation of your house. The fault undoubtedly lies in the after culture. Has the temperature been very high during the early part of the summer, so as to scorch the growth? Have you over-watered with liquid manures, or allowed the border to become too dry? It is a difficult point for anyone who does not see the plants, and could ask a question or two upon the spot, to decide or even give a good suggestion as to the cause of failure. We should be glad if you could write again and say a little more about your culture, as it is clearly no fault of house or soil.—Ed.

**Adiantums unhealthy** (*Newcastle*).—The fronds of Maiden-hair Fern sent are very small, and the plants, evidently enough, are in feeble health. Some cultivators are much too fond of pulling to pieces and repotting their plants. If it is desirable that the stock be rapidly increased in number, then dividing and repotting just when active growth commences in February or March are right enough, but there ought to be no over-potting. The finest plants, or those which produce the greatest number of extra good fronds, are those which are not repotted very often, every second or third year being quite often enough to shift the plants. When the pots are well filled with roots, soot-water or other only moderately strong liquid manure should be given frequently, and dryness at the roots not be tolerated at any time while the fronds are green. Excessive shade is not desirable, as this unduly weakens the fronds. What Adiantums like is an intermediate temperature, that is to say, something between the heat of a stove and the coolness of a greenhouse, a moderate amount of moisture in the atmosphere also being needed. Blinds should be run over the house or pit whenever the sun shines strongly on it, and if the plants are not crowded or frequently muddled about, they will thrive grandly. It is no uncommon occurrence to meet with plants 2 feet through in 9-inch, or even smaller, pots. A compost consisting of three parts of loam to one each of peat and leaf soil, with sharp sand added, is most suitable, but the peat may be dispensed with. Avoid sowing the new soil by over-watering. Never resort to overhead syringing, and do not cut many fronds from feeble plants.—Ed.

**Names of plants.**—*T. B. Durriss*.—1, *Ptelea trifoliata*; 2, *Euonymus europæus*; 3, *Rhamnus alaternus*.—*C. Mangles*.—1, *Momordica* sp.—*E. E. Stevenson*.—Roses, 1, not recognised; 2, *Mme. Chauvry*; 3, *Gen. Jacqueminot*; 4, *Mme. Lamhard*. *Yucca*: Ferns are attacked with brown scale. The best way will be to cut off the fronds and burn them.

**Names of fruit.**—*S. H. G.*—Apple Lanes' Prince Albert.—*X. Y.*—Apples, 1, Summer Orange; 2, Tower of Glamis; 3, Lane's Prince Albert. Plum sent when ripe.—*Dunum*.—Apples, 1, Empero Alexander; 2, not recognised; 3, Ashmead's Kernel; 4, Tower of Glamis; 5, Plum Cox's Emperor; 6, Jefferson.

No. 1244. SATURDAY, September 21, 1895. V. I. XLVIII.

"This is an Art  
Which does mend Nature: change it rather; but  
THE ART ITSELF IS NATURE."—Shakespeare.

## ROSE GARDEN.

### AUTUMN ROSES.

ALTHOUGH by common consent the Rose is the queen of flowers, the traditional error that associates it with the early summer months only is as yet all too common. If this is not so, why is it that we see scarcely any Roses at flower shows during the months of August and September, and that the inspection of gardens reveals a state of things not easy to understand and harder still to reconcile with the fact that the Rose of to-day is as much a flower of the autumn as it is of the summer, and even more delightful because more profuse in its later blooming? Nearly all the Rose growing that comes under the notice of the general public, and we might say absolutely all that is done by the many societies that are specially devoted to this flower, are based upon its past traditions and manifestly incomplete. The National Rose Society is a standing example of incapacity to realise or appreciate all that appertains to the title it assumes when it does nothing to show the general public the artistic aspect of Rose growing and the prolonged season of the flower's beauty, but contents itself with providing its votaries in the early Rose days with two or three opportunities of beating each other in the production of the biggest blooms—a very confined scope indeed for good and useful work, and quite inadequate as a means of representing the varied charms of Rose growth and blooming. All that is done publicly and collectively is identified with this aspect of Rose culture, and as far as the Rose societies are concerned, no autumn recognition of Roses is ever forthcoming. Roses there are, however, at the present time and in exceeding abundance. We are not inviting attention to a few lingering remnants that belong to a display of earlier months, but to a Rose picture, gay in refined colour, that gives effect without garishness, and that shows the fullest Rose beauty.

At the meeting of the R.H.S., held in the Chiswick Gardens last week, the great feature unquestionably was the large and beautiful exhibit of Roses in great variety made by Messrs. W. Paul and Son, of Waltham Cross, not of individual blooms set up in the conventional way, but bunches of many kinds, showing well what the Rose garden can yield at the present time. But even this display, admirable and instructive in its way, was but a faint foreshadowing of the autumn Rose beauty that we have since seen and enjoyed in the Waltham Cross Nursery.

One cannot certainly be accused of overstating the merits of the Rose as an autumn flower, or exaggerating its beauty when long lines and large breaks of well-known varieties are seen much more profuse in bloom than in the proverbial days of Roses. The lesson to be learned is to grow the best varieties and many of them, and then on a smaller scale, but equally as charming in a limited space, we may ensure Roses in abundance and picturesque effect. What a waste of space, indeed, to be giving Rose bushes a square yard of ground each when the same area would take a dozen bushes of certain kinds that would hide the ground completely and cover themselves in lavish bloom.

It goes without saying that to all who know Roses the Teas are pre-eminent at the present time, and although they have been often praised in these pages, it is impossible to pass unnoticed such sterling kinds as Marie van Houtte, Anna Olivier, Mme. Hoste, Mme. Falcot, Mme. Lambard, Sunset, Catherine Mermet, The Bride, Adam, Marie d'Orleans, and many more well-known varieties. Here are garden flowers that appeal to and abundantly satisfy all the senses, and yet in a recent addition to Rose literature it was said that the Rose was full of shortcomings as a garden flower. Who at the present time would exchange a bed of Tea Roses for one of scarlet Geraniums? and if we have gardens for the enjoyment they give us, why not seek it to the fullest extent by growing the flowers we love best? Among the Tea Roses (in addition to those that are now recognised as standard kinds) we noted several others more or less of recent origin abundantly fulfilling earlier promises of merit. Kaiserin Augusta Victoria—not a true Tea, perhaps, but with all the attributes of the best of that class—will certainly grow in popular favour as its merits become known; whilst in Mme. Pernet-Ducher and Gustave Regis we have two essentially garden Roses, and they were prominent here, bearing huge heads of many flowers in a variety of stages and gradations of colour from the rich yellow bud to the white fully-expanded bloom. These certainly are two notable additions to the list of Roses that will make the garden gay at this period. Of dwarfier growth, but a picture at any time, and a Rose that will always furnish a bouquet of lovely buds is Mme. Chedane Guinoisseau, by no means new perhaps, but slow in receiving the appreciation it deserves. G. Nabonnand, again, would be tabooed by those who would have all Roses as full and solid as a Cabbage, yet what a beauty it is, and altogether unique in its colouring, its broad petals spreading out like those of a Tulip in the sun and delicately margined with pink, which fades imperceptibly away in the creamy white ground colour. Grace Darling, Viscountess Folkestone and Camoens are an indispensable trio that were much in evidence, as also were La France and its so-called white counterpart, Augustine Guinoisseau, which really has no resemblance to La France, but stands out conspicuous on its own merits as one of the freest, sweetest and most persistent of bloomers. Even on the Hybrid Perpetuals flowers were fairly numerous. But at this time of the year the Teas almost monopolise admiration. After these come the Monthlies, and here again what possibilities there are for autumn Rose pictures. There were other things perhaps as good, but assuredly nothing better at the time of our visit than a large break of the old pink China or Monthly Rose glowing with hundreds of blooms. With this, Fellenberg, Cramoisi-Supérieur and Mme. Lanrette Messimy, what colour, fragrance and long-lasting beauty have we to make a feature of. Lastly, there are the Polyanthas, in which extremes truly meet, as they present the greatest flower profusion of all upon plants whose stature is dwarfed to a degree that would make them insignificant. The lines of plants even at this late date were quite smothered with flowers. They are not perhaps so important as the Teas and other kinds, but they are charming, and ably assist in filling up the very full measure of autumn Rose beauty.

Rose Maman Cochet is a Tea Rose that has a future before it. We have seen it in good form on several occasions this season, and in the Waltham Cross Nursery it is now carrying fine blooms.

In form, substance, and lovely rose-pink colour it much resembles Catherine Mermet, but is besides endowed with a vigorous growth, as evidenced by the long strong shoots it has this season sent up.

**Tea Rose Marie d'Orleans.**—This Rose was conspicuous in the Waltham Cross Nursery, the bushes carrying many beautiful blooms. It is a strong grower, abundant bloomer, distinct in form and colour, and always good. By some strange oversight its merits are known to but a few.

**Rose Christine de Neve.**—This proves to be a first-rate Rose, and though not exactly new is of comparatively recent origin. Its flowers, full and finely shaped, stand up erect, are of a deep rose colour in the centre, shading to crimson in the outer petals, and deliciously sweet. It was raised and sent out by Guillot, and this fact alone is strong testimony to its high merit.

**Rose Mme. Joseph Combet,** raised by Bonnaire, is one of last year's new Roses which attracted our attention at Waltham Cross. At a first glance it might be mistaken for Gloire Lyonnaise, it having the vigour and erect habit of growth of that kind, but its flowers appear to be fuller. They are of globular form and cream-white in colour.

**Rose Princess Alice de Monaco,** one of last year's new Roses, has been very charming lately in the Waltham Cross Nursery. In form and exquisite colouring it reminds one very much of Mme. de Watteville, having the same Tulip-shaped bloom, whilst in colour it is cream-white shading to deeper yellow at the base, but the petals are beautifully margined and flushed with a tender pink shade.

**Rose Clio** is one of the Waltham Cross Roses, and a first-rate addition to the very limited selection of those that bear light-coloured blooms in the H.P. class. It has besides everything to recommend it as a garden Rose, above all being endowed with a vigour almost equal to that of the strong growing Dijon Teas. Some of this year's shoots are over 6 feet in height, whilst bushes several years old are of great size. One need not hesitate to plant a group of this kind in order to make a Rose picture.

**Roses Bardou Job and Gloire des Rosomanes.**—Among many autumn Roses now flowering these two are conspicuous alike in profusion and brilliance. The cooler days of autumn are better suited to them, and their semi-double flowers last longer at this season. Here, indeed, are two grand Roses wherewith to enliven and put a little colour into the flowerless shrubberies. They only want to be treated as shrubs and allowed to have their own way.

**Rose Lorna Doone.**—Bourbon Roses as a class are lightly regarded at the present day, with one notable exception, viz., Souvenir de la Malmaison. In Lorna Doone we have a Bourbon that deserves popularity, as it is undoubtedly a grand garden Rose, as truly perpetual as the old Malmaison. Two groups of this kind at Waltham Cross were as beautiful as any Rose in June, every plant bearing fine flowers in quantity and many buds yet to expand. It was raised by Mr. W. Paul. Its flowers are large, full and sweet, of a deep rosy crimson colour, and displayed to the best advantage upon a plant of vigorous growth.

**Tea Rose Sylphe.**—This is a new variety of Mr. W. Paul's raising, and one of decided promise. It has a sturdy and free habit of growth and flowers of medium size, borne erect on long, strong stalks, that adapt it well for cutting. In its exquisite shades of white and blush-pink it gives us a flower of the same lovely tint as that of Souvenir d'Elise Vardon, and is a welcome acquisition on that account, as few can do anything with the latter kind.

**Rose Francis Dubreuil** is a red-flowered Tea that appears to possess more than an average degree of merit. It is certainly very much better than most of this class, which have been offered all too freely of late, but growers wisely have

accepted but a few of them. Francis Dubreuil was raised by Dubreuil, and is being sent out this autumn. We saw it at Waltham Cross and were decidedly impressed with it, as its colour is a deep crimson-red shading to a darker hue in the outer petals, but there is no suspicious purple tint that makes so many red Teas dreary-looking. The flowers, too, are well formed and borne erect upon strong shoots. It is a Rose worth trying and we shall watch its behaviour another year.

**Roses Duke of York and Queen Mab.**—These are two most noteworthy additions to the as yet meagre list of first-rate Monthly Roses, both of them having been raised in the Waltham Cross Nursery, and they are now flowering well there. The Duke of York would seem to do as well indoors as out, for early in the spring of the present year Messrs. W. Paul and Son showed a group of pot plants of this variety in abundant bloom. If proof were wanting of its continuity it is forthcoming to the fullest degree, as we lately saw these same plants still under glass and bearing their fourth crop of flowers this season. Two round beds of Duke of York filled with this variety were also charming. The form of the flower and the exquisite variation of its colouring recall the Tea Rose *Homère*, but for open-air growth Duke of York is far ahead of that kind. The buds are of much better form than those of Monthly Roses generally, and in this state of a deep rose-pink colour, but they expand into flowers that shade to pink, curiously mottled with white. Queen Mab is of more recent origin, but we venture to predict that it will have many admirers. Its flowers are of a pretty form and tender colour, a pale salmon tint, flushed with pink and shaded with copper-yellow at the base. In growth and freedom of blooming it appears to be all that one can desire.

## FLOWER GARDEN.

### FLOWER GARDEN NOTES.

It often happens in the case of newly-formed herbageous borders that they cannot be filled the first year with permanent plants, and when this is so recourse is had for the first summer season to some of the most enduring of the annuals or ordinary bedding plants of a tender nature in such varieties as will adapt themselves the most readily to the surroundings. By the end of the present month these flowers will, however, have served their end and be decidedly on the wane, and so soon as an opportunity offers and they can be cleared away, the spaces can be filled in with those herbageous plants that have been prepared for the purpose, such things, for instance, as *Polyanthuses* and *Campanulas* from seed, *Pinks* and *Violas* from cuttings, *Carnations* from layers, and others possibly from division. These are all front row plants, that are to be planted in bold groups towards the front of the border; the back and centre are more readily filled, for the simple reason that the plants occupying such positions are stronger growers, they quickly fill up large spaces of bare ground, and are, as a rule, nearly all amenable to propagation by division, an easy and expeditious way of increasing the stock when a few of each species or variety have once been acquired. In the case alike of seedlings, cuttings, layers, or divided plants, it will be found advisable to give a thorough soaking before lifting if the weather is inclined to be dry, and to perform the operation carefully with the view of preserving the roots intact. It is of little use taking the trouble to prepare a good plant if at lifting time it is to be dragged or pulled out of the ground. The spaces intended for autumn planting should, when the summer stuff is removed, get a liberal dose of short manure, be deeply forked, and well broken up. If it is decided to have a few clumps of *Daffodils* in the regular herbageous borders, I should strongly recommend the choice of fairly high class varieties: it is very seldom that they

can be acquired in quantity for massing in the wild garden, but sufficient may be obtained for clumps of a size that will correspond with the surrounding groups of herbageous plants. Half-a-dozen good ones would be *Emperor*, *Empress*, *Hersfieldi*, *maximus*, *Sir Watkin*, and *Barri cespiciosus*. These rank among the medium-priced varieties, which everyone should grow if only in small quantities. They are sometimes mixed with *Polyanthuses* or *Primroses*, but I am not in favour of such a style of planting. It has an unnatural patchy appearance. It is better to plant them alone, covering the ground after the foliage is gone with some dwarf annual, or if a permanent carpet is required, with some of the dwarfiest of the alpine *Phloxes*. One piece of work in the herbageous border that must not be neglected when any plants are lifted for propagation is to see to the removal of any obnoxious weeds that may have found their way into the border. Some years ago I had given me a lot of herbageous plants to fill in the side of a hill that was to be planted with alternate clumps of these and flowering shrubs. The stuff was not thoroughly examined, but planted straight away as it came, with the result that the following season I had goodly crops of *Prickly Comfrey*, *Couch Grass*, *Ground Elder* and *Bindweed*. The experience thus gained taught me the lesson of shaking out, washing if need be all soil from the crowns and examining the soil for any objectionable subjects. Once planted the spreading capacity of the weeds above-mentioned is so great, that they are with great difficulty eradicated, especially if they have managed to establish themselves in the crowns of the plants. In some cases it is not altogether an easy matter to distinguish the root of the weed from that of the plant among which it may be entwined. That very objectionable pest, for instance, known as *Ground Elder*, is almost indistinguishable from the *Alstroemerias* or *Tropaeolum speciosum*. Also following up the idea of cleanliness and order, it may be noted that where borders are left a bit to themselves that is not kept too stiff and formal, stray plants are often apt to make their appearance, and these may be promptly and carefully removed. A judicious mixture is always welcome, but, as noted in the case of the *Polyanthuses* and *Daffodils*, anything patchy or unnatural is foreign to true flower gardening.

**LIFTING TENDER PLANTS.**—With September drawing to a close one can never be sure of the weather, and the early approach of frost being very probable, we finished last week running the spade round several tender plants with the view to their early lifting. A careful examination of the large-flowered *Paris Daisies* reveals the fact that they are this year quite free of the leaf-boring maggot, and a good batch of both white and yellow varieties will come up. They come in very acceptable for cutting when the frost has cleared the borders of outdoor flowers and stand well in water. If the plants are large, it is advisable to choose a dull day for the lifting, performing the operation carefully. Pot up directly, give a good soaking of water and stand them in the shade for a few days until they have recovered from the check caused by removal. If the small-flowered variety is grown, a few of this may also be lifted, for if the flowers are not so useful the plants will help to brighten the conservatory until the *Chrysanthemums* are ready, and may also be employed for various purposes. Nice plants from a good strain of *Margarita Carnations* may also be potted up; those from late sowings will now be just coming into flower and be bristling with flower-buds. Care must, however, be taken on no account to put them anywhere near the pot varieties (either winter or spring-flowering) if there is any sign of disease on them. I heard of a case last year where the disease was believed to have been transmitted to choicer kinds by bringing in a lot of *Margarita*. The inference may have been wrong, but it is as well to be on the safe side. *Cannas*, with their striking foliage, often come in very handy where the supply of large *Palms* and *Dracenas* is not extensive, and a few of the best

and most shapely can be lifted, also the best of *Grevillea robusta*, if provision has not been made to grow on a supply in pots. It may be noted before leaving this subject that if there is anything in the way of bedding stuff of which the stock is limited, and of which sufficient cuttings could not be secured, it will be well to lift and pot a few plants from which cuttings can be taken in the spring. A good supply of dwarf *Ageratum* can often be secured in this way when the amount of cuttings obtainable in the autumn is very small. It is a good plan to look through beds of seedling *Petunias* and *Verbenas* to see if one has anything special; sometimes one or two may be considerably in advance of existing varieties, and the old plants may in this case be also potted up.

**LOBELIA CARDINALIS AND L. FULGENS.**—As the time for lifting these (where they are growing in situations rendering their removal necessary) is now close at hand, I should like to ask correspondents who annually complain of losses whether water is given through the winter months, as on comparing notes with a friend—who also said three parts of his stock was generally missing in the spring—the question of water or no water seemed the only point of difference between us. My plants are put into ordinary border soil that is fairly moist as thickly as I can pack them, and do not get a drop of water until they are pulled to pieces and re-boxed in spring ready for a start. It may perhaps be hardly necessary to give the reminder that before the approach of frost all plants of a permanent character at all tender that have helped in the summer flower garden should be housed, and these that are getting a bit leggy, such as the green-leaved *Dracenas*, *Ficus*, &c. (which may be improved by the stem rooting in damp Moss and the consequent cutting over and potting of the newly-formed plant) should be stored away thickly pending the operation.

Claremont.

E. BURRELL.

### NOTES ON HARDY PLANTS.

**Megaseas.**—It would seem that to be loyal to the "Kew Hand-list of Herbageous Plants, 1895," this generic name is to become obsolete, and this section of plants is to range under the generic name *Saxifraga*, as of yore. No doubt the best of reasons—botanical—can be given for what has been done, and it must be quite right; still, it is equally true that these changes—and especially such as the present change—are most inconvenient and even impracticable for trade list purposes. However loyal tradesmen may desire to be, it takes years sometimes to alter a set of names; and here, almost before *Megasea* had become generally recognised, it has to be struck out and the species must go back to *Saxifraga*. The question is, what can be done? for if the name *Megasea* was an error, nobody can fairly object to the correction in the Kew list. But it may be useful to point out that the most painstaking of tradesmen have great difficulties in trying to keep pace with these changes, and many have grown so tired of the alteration of names that they do not care to follow it. This is all worthy of the consideration of botanists, for few will dispute the fact that trade lists are those most commonly read and quoted by gardeners. In other words, excepting where the errors are great or genera become too comprehensive, plantsmen should be taken into the confidence of botanists, and changes, other than those absolutely needed, should be avoided, as where an existing name will do let it alone rather than change for another, though perhaps a little more proper. A method aiming at uniform nomenclature can only defeat its own object unless the trade prints can be brought into harmony with the botanical ones within a reasonable space of time, i.e., as regards names being changed.

**Primula Rusbyi.**—This rare American species is one of the last of the hardy species to flower, and it is blooming now. In every way it is a pleasing *Primrose*, habit neat and distinct, foliage so sharply toothed as to be almost spiny; flowers of a distinct and bright amaranth-purple,

intensified by the farinose scapes and calyces. The latter have thin divisions, so narrow and pointed as to resemble silver lines on the coloured corolla tube. The trusses of flowers are one sided in the way of the common Auricula, the pips being about two-thirds the size. I have found the plant somewhat tardy during an experience with it of six years, but since I used Moss with the compost I get it on more quickly.

**Lathyrus maritimus.**—Though a British species it is not a common one, and it is by no means a commonplace plant for the garden. Used properly on the rockery or on sunny banks it is charming. Its flowers were rose and purple of bright hues, borne in neat drooping bunches, lasting a long time, both individually and in succession. The stems, of moderate length, look best when allowed to run on the surface or hang over a broad ledge of rock. The thick and glaucous foliage, almost blue, is spreading and flat, with the leaflets so obtuse as to be practically round. For a Pea its habit is compact. I have grown it many years, and by the way it attracts notice I should say it would be a plant that would have many admirers.

**Lathyrus latifolius Turneri.**—A specimen on a sunny bank and about three years old is now a glorious mass of bright fresh herbage and striking rosy red spikes of numerous big flowers, in these respects excelling the type, but its chief point of superiority is its greater profusion of blossom. It is probable some might take it for a better specimen of the type only, but seen side by side its distinctions are obvious. The stems are shorter-jointed, and as every joint produces a big bunch of flowers, the plant, which is 9 feet across, may be readily imagined to be a gay object.

Woodville, Kirkstall.

J. Wood.

#### POMPON DAHLIAS.

NEW varieties come less freely than in the Cactus section, but there is in the pompon strain less of room for improvement, so perfect in form and doubleness are the established varieties. Really there seems no room whatever for development in form or doubleness, and novelties exhibit chiefly new or diverse hues of colour or markings. It is, however, noteworthy that the best or prettiest and for cutting most useful flowers are those of self colours. I noted with special satisfaction in this section of flowers at the recent Royal Aquarium show that the judges selected the smallest blooms for the best position. On the whole, in the other collections size in these flowers was less apparent than was seen in some previous years. Let us hope that henceforth large pompon flowers will not be staged or, if possible, even grown. The charm of these lies in the fact that they are miniature reproductions of the big, massive show flowers, and if relatively just as rotund and as solid, may even formal, yet their very littleness serves to excuse much that it is not easy to overlook in the large-flowered sections. Whilst we admire the round balls of petals which make up flowers of a Viburnum, we cannot very well refuse to appreciate the less stiff and far more vari-coloured double flowers of pompon Dahlias. It is sometimes suggested that these Dahlias made good summer bedders. From the purely massing aspect in flower gardening that is so, but they are best planted here and there in shrubby borders if to be decorative, or if wanted only to furnish flowers for cutting, then they should be planted in some out-of-the-way corner of the kitchen garden. The modern method of exhibiting Dahlias of the smaller-flowered sections in bunches of six by the aid of wire frames is no doubt helpful in securing each flower in position and enabling each one to be readily seen. So far that is well. None the less, the method does not commend itself to those who desire to see flowers gracefully arranged, and we may well hope that wire frames of this description will never be tolerated in association with Chrysanthemums. Whilst a mere wire support to weak-stemmed flowers is not objection-

able, I am not sure whether it may not be possible with the aid of a little wire round the stems to exhibit all Dahlia flowers much more pleasingly than any other method admits of. A. D.

#### ERITRICHUM STRICTUM, OR NOTHOFULVUM?

A most beautiful and continuously free-blooming hardy annual was sent to me under the former of the above names in the spring of last year by the Rev. Theodore Marsh, whose beautiful hybrid Lachenaliae were figured in THE GARDEN on Sept. 29, 1894. He wrote to me when sending the seed that it had deep blue flowers, and that being perfectly hardy it required no special care, and usually sowed its own seed freely all round wherever it grew, so that by transplanting the seedlings in the spring it could be made use of wherever a border of blue flowers was wanted in the garden. I transplanted my self-sown seedlings accordingly this spring round one of my beds of M. Lemoine's hardy hybrid Gladioli, where they have bloomed continuously and most profusely during the whole summer, and have been much admired by all visitors to my garden, to none of whom was the plant known, and nearly everyone asked for the name and wished to know where he could obtain seed of it for next year's bloom. The small deep blue flowers, which are produced in groups of two or three all up the long flower stem, exhale a strong perfume somewhat resembling that of the common Lime tree, and during the sunny hours of the morning they are covered with flies, bees, and other insects, who seem to find their odour very attractive. I have not been able to find either name in any of my botanical books of reference except the great "Index Kewensis," where both are mentioned. The horticultural dictionaries only mention one species of the family, the pretty little turquoise-blue-flowered alpine trailer, *Eritrichium nanum*, so difficult to manage in British gardens. I sent some flowering specimens of my plant to a London nurseryman, who tells me he sells seed of it under the name of *Eritrichium nothofulvum*. On referring to the "Index Kewensis" for the second specific name above mentioned, I find it is said to be synonymous with *Plagiobothrys nothofulvus*. I also sent flowering specimens to the herbarium at Kew for identification, and the learned botanical authorities there informed me that it was not an *Eritrichium* at all, but apparently a member of the Hound's-tongue family, *Cynoglossum furcatum*, figured by Wight in his "Illustrations of East Indian Plants," vol. iv., plate 1395. I hope that some of your readers will recognise and be able to give the correct name of this plant.

W. E. GUMBLETON.

**Androsace sarmentosa.**—Reference is made on p. 101 and again on p. 175 to this *Androsace* as well as to others. I manage this variety well by layering, as it were, the runner-like growths that so freely push from the base of the plant. Instead of pegging them down to the soil I lay a small piece of stone upon the stem of the runners, and the cushion-like growth springs up close to it. The stones retain the moisture in the soil, which this plant enjoys, without keeping the foliage continually wet.—E. M.

**Hollyhocks.**—It is disappointing to find so few of these noble border flowers in gardens. Relatively a far finer display of them is sometimes seen in a good cottage garden than in a large garden. The disease which used to present so much trouble to Hollyhock growers has not been so harmful of late, and there can be no doubt that the sowing every year of a good strain of seed the old plants so soon as they become weak being rooted out and burnt, helps materially to baffle the fungus, owing to the young plants having so much more vitality. It is not too late to sow seed now in pans or shallow boxes stood in a frame or greenhouse. Then, later, either prick out the seedlings singly into small pots, or thinly into boxes or pans, winter them in a frame and they

will be strong to turn outdoors in April. As a rule, such plants will bloom finely in the autumn, and the following year even more so.—A. D.

**Cestrum Parqui.**—This is the hardiest of all the species and is grown quite without protection in the Jardin des Plantes of Paris. Here it is planted at the foot of a wall, where it attains a height of about 4 feet, producing a large number of panicles 7 inches or 8 inches high, with flowers of very pale yellow. The corolla tube is three-quarters of an inch long with starry rays spreading to a diameter of half an inch. The leaves are lanceolate and the entire plant is glabrous. It is a little-known plant, a native of South America, and of interest to collectors of hardy plants.—R. I. LYNCH, Cambridge.

**Papaver glaucum.**—Of all the annual Poppies not yet improved by the florist, this is no doubt the most gorgeous. It grows about 2 feet high and has very distinct glaucous leaves quite unlike those of any other species. The flowers are each about 3 inches across, and while the outer petals expand, two of the inner ones curve like shells over the essential organs in the centre, which they protect. These petals have each a black blotch at the base, but the flower otherwise is intensely scarlet. It is known as the Tulip Poppy and is a native of Syria.—R. I. LYNCH, Cambridge.

#### PHLOXES AT CHISWICK.

It is a long time since we have had an opportunity of inspecting a full collection of Phloxes such as that which has been got together and grown at Chiswick this year. It would be a gratifying result of this trial if it gave an impetus to Phlox culture in private gardens where we rarely see this fine flower well grown, although it has a brightness and force of colour that we can ill afford to shut out of our gardens in late summer and early autumn. As might be expected in so large a collection, there are some duplicates and not a few varieties too much alike, but there are besides some kinds of sterling merit that we have endeavoured to select and enumerate for the guidance of planters. If those mentioned below are added to the selection previously given in THE GARDEN for August 10, p. 99, a choice lot of the finest varieties extant, and which deserves good culture in gardens, may be secured. Embasement has large flowers of a clear cerise-red colour, and the habit of growth is dwarf and sturdy, whilst Alexander Shearer, a dwarf free kind, has fine self-coloured flowers of a bright red shade, most effective and beautiful. Neptune has flowers of a lovely soft rose shade, whilst its habit is dwarf and free and the flower-trusses large. Granville, with flowers of the purest white, is charming, and noticeable for its sturdy habit and dwarfness, bearing immense trusses of bloom on strong, erect stems. Faust, also white, is varied with a soft pink eye, the flowers individually large and lovely, whilst in freedom of blooming it is all that can be desired. Leonie is fine, with large flowers and trusses, in colour a deep rose, with a small dark crimson eye that imparts a special richness to its effect. It is of medium height and very free-blooming, whilst the same may be said of W. Robinson, which is one of the best Phloxes, and should be included in the smallest collection. Its flowers are very fine, of a clear soft rose-pink colour, with a darker eye, and the lateral trusses, together with the terminal ones, make a great display of bloom. Etia must not be omitted, for although not new, it loses nothing by comparison with any in the collection, and has few equals in its own glowing red shade.

#### SHORT NOTES.—FLOWER.

**Cactus Dahlia Lady Penzance.**—This is a first-rate variety. The form is very beautiful and the colour (yellow) soft and clear. The blooms are medium-sized, freely produced, and the plant remarkably dwarf and bushy.—H.

**Physalis Alkekengi.**—I note on p. 196 reference is made to this Winter Cherry not having yet

coloured, but remaining still green. Here we have much of it in various situations, and in all cases quite half of the calyces are already beautifully coloured.—E. M.

**Cactus Dahlia Mrs. Peart.**—I am disappointed with this variety, which has been much talked of as the finest pure white of true Cactus form. It appears to me to be neither. The form is confused and the centre badly filled; the colour is really a lemon-white. Whether it will produce good blossoms by severe disbudding I am unable to say. For general culture the variety cannot become popular.—H.

## KITCHEN GARDEN.

### SPRING-SOWN ONIONS.

At some of the west of England shows the judges have decided against awarding prizes to Onions shown as "spring sown," but which obviously were raised under glass and planted out, thereby reviving and giving prominence to an old grievance among gardeners and cottagers. I hold that a mistake was made by those judges, and an injustice was done to several deserving exhibitors. If the schedules expressly stated that spring-sown Onions must be raised in the open the case would be different, but it is merely stipulated that these should be spring-sown, and who shall say when spring commences? Even if March 1 was defined as the first day of spring, it would be possible to raise the plants under glass, plant out, and surpass those grown where sown. Not only have I frequently advised gardeners and cottagers to raise a stock of white Spanish Onions in boxes under glass and plant out when about 4 inches high, weather and state of ground permitting, but I have also done my best to persuade market growers to adopt a similar practice on a large scale. It has been found to pay remarkably well in America, and why not in this country? Light, glazed, heated houses would be preferable to frames for the purpose of raising the plants, the simple plan of sowing somewhat thickly in boxes being adopted. If the seed were sown early in February, by the end of March or early in April all could be cleared out and a crop of Tomatoes follow. At first sight so much extra labour and expense may seem altogether unnecessary, but when it is seen how much less seed is required; how evenly and quickly the ground can be cropped; how much less likely these early raised plants are to be damaged by the Onion grub or over-run by mildew; how much finer and handsomer the generality of the roots become as compared with any sown in the open; and lastly, how much more surely perfect maturation takes place, there will be few objections raised. As far as the south of England is concerned, I am of opinion that poorer crops of Onions were never seen. Exceptionally hot and dry weather early in the summer effectually checked the growth of the bulk of plants raised in the open, but before they formed "bulbs" rainy weather set in and growth recommenced, the result being large breadths with scarcely a well-matured root among them. Where left untouched the majority are still very green and erect, maturation apparently being far off, while drawing early and attempting to harvest artificially will meet with but scant success. There is, therefore, every probability of their keeping badly and an early break-down in the supply taking place. In many cases there are no signs of bulbing, and all such Onions I advise leaving where they are, or else that they be transplanted elsewhere. They will withstand a moderately severe frost, and may prove very

acceptable in the kitchen next spring. Compare the crops of Onions grown where sown with those raised under glass and planted out, and the verdict must be altogether in favour of the latter. There is scarcely a small or an indifferently matured root among the latter, and so much have several intelligent cottagers been impressed with the superiority of the plan, that they have decided to sow no more Onions in the open—at any rate other than in the autumn. They raise their plants in frames. The plan should be encouraged, not discouraged.

W. IGGULDEN.

**Kidney and round Potatoes.**—There is much in what "A. D." says (p. 178) as to the difficulties of classifying some sorts of Potatoes. At a recent exhibition where I was judging, the finest dish of kidney Potatoes was Satisfaction, and in the round division this variety also was by far the best dish. Here was a difficulty. How could this Potato be set up as an ideal kidney variety and also be shown as a round? As the Potato shown as a kidney more resembled a good form of that type, this was awarded premier honours, while the other dish was passed.—E.

**The seed crops.**—It is to be feared that the seed crop of 1895 will be much below the average. In travelling through various seed-growing districts a few days ago I could not help noticing how very short the stems of seed Onions were, the heads, of course, being correspondingly small. This is due to the great drought, which came just at a critical period of growth. Beet will, I fear, be poor both in bulk and quality, owing to a late growth and a deficiency of root moisture, and the same may be said of Mangolds. I notice also in the Bedfordshire districts that Coleworts intended for early winter consumption were looking very blue and stunted, the ground not having been sufficiently moistened after the removal of Peas and Beans to give the roots a fair start. A noted London seedsman told me that the earlier varieties of Peas were harvested in a fairly satisfactory condition, but that he feared later sorts would be inferior.—J. C.

**Tomatoes.**—Amongst varieties or assumed varieties, for differences are very minute with many, that have recently come to the front is one named Polegate. It is a fine deep-coloured selection, from Perfection no doubt. I find it is held in great favour by some growers of vegetables for exhibition, for it furnishes handsome samples. Still, I have seen plenty of the Perfection type in past years quite as good as Polegate now furnishes. The variety was shown well at the Crystal Palace fruit show last year. A few dozen selected fruits on a show table, however, barely convey all that it is desirable to know concerning Tomatoes, because there remain the subjects of cropping, of flavour, and density of flesh. We have not yet reached to the point of testing Tomatoes as we do Turnips, Beet, &c., to ascertain quality of flesh, but I think it is nearly time we did. When the core cuts pale in colour and the seed pockets are large, then the fruits are far from being meritorious. A very good test is found in cutting fruits through from the stem, but the best is found when the cut is transverse, as then all the weak features of the fruits are fully exposed. I think we cannot well give too much weight to colour and solidity of flesh. The present season bids fair to be a record one for outdoor Tomatoes, for the crop is remarkable and will generally ripen well.—A. D.

**Cauliflower Eclipse.**—To fill the breach between the midseason and autumn Cauliflowers the one above named is of great value, and but for this I should not now have any for use. It is very similar in its style of growth to the well-known Autumn Giant, and may very easily be taken for that kind by those unacquainted with it. The latter variety is a great favourite among exhibitors for the autumn and late summer shows, and one

having the same characteristics that will be ready for use in August from an outdoor sowing made in March must be welcomed by exhibitors and others. It is true there are other kinds quite as reliable for autumn use as the Eclipse; still that does not detract from the value of the one under notice, because the Autumn Giant type is not so liable to go blind as the smaller growing summer kinds, nor lose colour so quickly when fully grown, because they are protected by the upright and ample foliage more perfectly than in others well known and valuable for the summer months. Unless the Autumn Giant is sown very early in the year it cannot generally be depended on to mature early in August, but with this sort there is no difficulty in having matured heads at the time named from an ordinary March sowing. There is no doubt that this variety will become popular when its merits are more widely known among all classes of cultivators, and it is certainly deserving of extended cultivation.—W. S.

**Shallots.**—The true old Shallot, in the rage for size, seems to be in danger of getting pushed out of cultivation by the large red Jersey variety, which is much less handsome and not possessing in so high a degree that pleasing piquant nutty flavour which characterises the true Shallot. The Large red is of almost as coarse texture and appearance as the Potato or underground Onion; indeed, one often sees at shows bulbs that are sent as Shallots, but which are auspiciously like this root. I find Shallots are grown very largely indeed in cottage gardens and allotments in Surrey, but the Jersey is the most predominant. Some of the handsomest bulbs of the true form I have seen were shown the other day by cottagers at Shrewsbury, the best samples being singularly fine of their kind, clean, smooth, and handsome. It was very interesting here to note, for there were probably thirty dishes staged in one class, that the judges selected for the first prize large and far from clean or pretty Jerseys; then meet oddly they went to a beautiful sample of the old Shallot, not one half the size of the Jerseys; then they again, with curious inconsistency, went to the large Jersey; and then fourth to pretty old Shallots; and fifth and sixth to the large Jersey again, making confusion of awards worse confounded. I hope the Shrewsbury committee will next year make separate classes for both forms, and thus prevent such contradictory awards from being again made. I venture to hope also that wherever both varieties are shown in the same competition, the undoubted high quality of the old Shallot will not be overlooked in presence of the bigger coarse form of the large Jersey.—A. D.

**Potato Boston Q. Q.**—This modern Potato, which claims quality and quantity as its title, is, under a trial given it here, quite deserving of its name. The yield from 5 lbs. planted in April was 110 lbs., and as the seed was necessarily cut, through being so large when purchased, I think the quantity was very satisfactory, for, no doubt, had the seed been of an uniform planting size, the same weight would have given a much larger yield. The tubers, many of them, were large and distinctly handsome in shape, the fault, if any, being found in the depth of the eye, which is more pronounced than in many fashionable Potatoes now. The quantity of tubers of seed size produced is very small, and no trace of disease was found when lifted. Quality depends entirely on soil and cultivation, but in ours, which is not famous for producing high quality, there is no fault to be found with it, and no doubt, in good Potato land, it would prove a first class sort in every respect. In the haulm it is of medium strength, a point favourable to small garden and field culture where wide planting is not generally practised. Those who have an interest in planting new kinds with a view to proving their respective merits would do well to give Boston Q. Q. a trial, and if the results generally equal those obtained under its first trial with me it will become a favourite. It is a white-skinned and bright-looking tuber, and ought to make a very good addition to the many exhibition sorts of Potatoes.—W. S., *Trowbridge.*

## STOVE AND GREENHOUSE.

## EUCHARIS GRANDIFLORA.

IN most gardens the attempt is made to grow a batch of *Eucharis grandiflora*, or *E. amazonica*, as most often termed, but only in a few cases are the plants to be seen in such an admirable condition as in the illustration accompanying these remarks. Nothing proves more vexatious than a sickly batch of this *Eucharis*, while, on the other hand, a healthy group is a source of pride to the grower. Those who fail attach all the blame to the *Eucharis* mite; those who succeed snap their fingers at the latter, and consider it a bugbear that to them has no terrors. Without wholly agreeing with the latter, I am yet disposed to think it less difficult to contend with than many gardeners seem to think. Once the plants get into a sickly, unhealthy state, the mite takes possession of the bulbs, and the chances are no further healthy growth is ever made. Gardeners

give their plants a shift, and when they reach the size shown in the photograph it is not often they are shifted into larger sizes before the roots actually crack the pots in which they are confined.

When the plants are sickly and mites are swarming between the scales, a somewhat different method of procedure is desirable. Cut off the leaves, as they hinder, rather than forward, root action; remove the outer scales from the bulbs, and soak for not less than three days in a strong solution of Gishurst compound, lemon oil used at the strength recommended by the vendors also answering well. In my opinion, however, clear water is equally efficacious, always provided the bulbs are wholly and constantly immersed in it for three days; but this remedy never seems drastic enough to those whose plants have been long troubled with the mite. Re-start either singly or in groups of a few bulbs in small pots rather than in 10-inch or larger sizes. Use a compost that will not readily sour, a mixture of two parts of

and a knowledge of this fact has been the forerunner of very many failures. One method of causing the bulbs to flower at a fixed date has already been alluded to, and another consists in placing the plants in a lower temperature than previously grown in, drying off also forming part of the resting. After this enforced rest a sudden change to a strong heat and moist atmosphere causes flowering to take place very quickly, but this somewhat unnatural treatment not infrequently leads to an attack of the mite, or, at any rate, greatly weakens the bulbs. After a crop of leaves is fully matured a rest is desirable, but this can be accomplished without moving the plants. A rather lower temperature and less moisture should be given for three weeks or longer, when a sudden increase in the temperature and more water at the roots will rush up the flower-scapes in profusion. Unless a heavy supply of bloom is required at some particular time, there need be no special measures resorted to. When the pots are full of roots and the foliage healthy

*Eucharis amazonica.* From a photograph of a group in Mr. G. A. Turbutt's garden, Ogston Hall, Alfreton, by Messrs. Seaman and Sons, Chesterfield.

are very fond of shaking out and repotting their bulbs, and once too often the "pitcher goes to the well." Shaking the roots clear of soil and repotting were long thought desirable, if only with a view to cause the bulbs to flower soon after, those responsible quite overlooking the fact that the same bulbs would have flowered, it may be, a few weeks later if not excited in that way. Under favourable conditions these repotted bulbs soon recover from the check they receive and make good progress, but should they be neglected or be given sufficient water to sour the soil before the roots have a chance to well occupy it, the mite and its destructive habits are soon heard of. Some of the finest pots of bulbs I have ever seen were the offspring of a single bulb, and no shaking clear of the soil was ever practised. Sometimes, instead of one strong bulb being started in a 4-inch pot, three are placed in either a 5-inch or 6-inch pot, and from these they are gradually shifted into larger sizes. Those who are wise are in no great hurry to

good fibrous loam to one of the best leaf-soil procurable, with sharp sand, charcoal and a sprinkling of burn-bake added, being suitable. When they want manure it can be given them in a liquid state, and the two last-named constituents will both ensure porosity and prevent souring. Give the sickly bulbs the benefit of a fairly brisk bottom-heat, and do not water beyond what is necessary to keep the soil from becoming very dry. When root action is going on briskly, give more water and gradually raise the pots to the surface of the bed. It is the plunged plants that are most likely to suffer from over-watering, and worms are very plentiful in many old hotbeds. The pots should be arranged on a slate bench or slate-covered staging and ashes on this, the latter being kept constantly moist. In the temperature of an ordinary plant stove the pots arranged on a staging get quite as much bottom heat as they need.

It is possible to flower well-established plants of *Eucharis* three times in the course of a year,

there will nearly always be a few or many flower-scapes showing, a sudden change from dull to bright days frequently stimulating flowering on a large scale. The plants will require assistance at the roots, and nothing answers so well as clear soot water.

The greatest importance ought to be attached to the preservation of the leaves in a healthy state. They are more sensitive than they appear to be. Too much sunshine is most injurious, and neglecting to shade in good time has been the cause of wholesale losses of leaves. I find a covering of *Stephanotis floribunda*, with a blind run over on hot clear days, none too much shade for *Eucharis*, and each time pot plants were shifted to less well-shaded positions they have suffered badly. Mealy bug and thrips are terrible scourges, and both have been the ruin of innumerable plants, outdistancing the mite in this respect. Any insecticides I have ever tried that were powerful enough to destroy these insect pests were also capable of ruining the *Eucharis* foliage. Sponging

is the remedy for both, but it should be done with moderately hot soapy water, and not a strong insecticide.  
W. IGGULDEN.

**Lilium neilgherrense.**—Out of a number of bulbs of this Indian Lily imported last spring a few flowered quite early in August, and now there are several others in bloom, thus anticipating their usual season of flowering, for they may sometimes be had till nearly Christmas. No particular treatment was given to bring about this result, as the bulbs were simply potted and placed in a cold frame, then as they started into growth early in the summer they were plunged outside till the buds were on the point of expanding. This is certainly a very distinct Lily, and valuable too from the fact that it is the latest member of the genus to unfold its flowers. The long tube-shaped blossoms are generally more or less of a creamy tint, but in this respect they vary somewhat, as they do also in the length and size of the tube, some being narrower than others. Occasionally, too, a flower will be found slightly suffused with purple on the exterior. Though this Lily as a rule flowers when there are none of its class to compete with it, yet it is not often met with, owing no doubt to the fact that the bulbs are always comparatively dear. The reason of this is it does not succeed under cultivation, hence continual importations are necessary. True, the bulbs flower well the first season, but the following year the display is much less, and after that the yield of blossoms cannot be depended upon. Although the whole of our bulbs were subjected to the same treatment, yet some of the plants are only just showing their buds, while in the case of the earliest the flowers are already over. The flowers of *L. neilgherrense* emit a very pleasing fragrance, quite distinct from that of any other Lily. Even when shrivelled on arrival the bulbs of this Lily soon recover their plumpness if potted as soon as possible in fairly moist soil. From the time of the year the blossoms expand it is essentially a greenhouse plant; indeed that amount of protection is necessary in order to ensure it passing unscathed through the winter. The blossoms of this Lily are thick in texture, and remain in beauty a considerable time, especially when they open later on, and the weather is consequently cooler than it is at present.—H. P.

**Primula obconica.**—It will be remembered that a considerable number of letters have appeared from time to time in connection with the above *Primula*, setting forth the inconvenience caused to many who had the handling of it in the way of great irritation of the skin, intolerable itching, &c. An experience that came under my notice the other day goes a lot further than this, and proves that *Primula obconica* may be a very objectionable, and even dangerous plant. A lady who takes a considerable amount of pride in her window plants had some half a dozen of the *Primula* given her, and seems to have paid a lot of attention to them in the way of picking over, tying, &c. Some month or so after the *Primulas* had been in the house their owner had a very aggravated form of the *obconica* disease, the itching being accompanied by pain, large red blotches appeared, and face, hands, and arms were very much swollen. Local medical men could make nothing of it, and the hospital authorities, who were at length applied to, were equally at a loss. The usual suggestion after seeing the patient for the first time being that it was a hereditary skin disease of a peculiar kind. At last someone (after the expiration of some months' attack), happening to be aware of the reputation of the *Primula*, suggested its removal, and, free from all contact with it, the patient quickly recovered, and has been quite exempt from any sign of the visitation. I thought it might be as well to note the matter in *THE GARDEN* columns, in case there are experiences of a similar nature. Will any correspondent who has had personal experience of trouble with the plant kindly say if it has been satisfactorily proved what part of it causes this skin disease? I was always under the

impression that it was the foliage, but was assured the other day it was the pollen from the flower. As it is a good plan to ventilate the fact that a peculiar affection of the skin is caused by the plant, it is also advisable to know exactly how it is caused. I have grown it here for years without anyone who has had anything to do with it being inconvenienced in any way.—E. BURRELL, Clarendon.

**Lilium Meximowiczii.**—This Lily has certainly been liberally treated in the matter of names, for besides that at the head of this note it is also known as *L. jucundum* and *L. pseudo-tigrinum*, while by some authorities it is regarded as a variety of the Tiger Lily. The theory has been put forward that it may be a hybrid between the Tiger Lily and the pretty Japanese *L. Leichtlini*, and I am certainly inclined to support this view, as it is in many respects intermediate between these two Lilies. In colour it more nearly resembles *L. tigrinum* than it does *Leichtlini's* Lily, and it is especially valuable from the fact that it tends to lengthen the Tiger Lily season, as they are all over or nearly so before *L. Maximowiczii* commences to bloom. This last differs from *L. tigrinum* besides its period of blooming in being a far more slender plant, with longer and narrower leaves, while small bulbils are not produced in the axils of the leaves as they are in the different forms of the Tiger Lily. The bulbs of *L. Maximowiczii* are very like those of *L. Leichtlini*, while those of another species that they may easily be confounded with are those of the upright-flowered apricot coloured *L. Batemanna*. *L. Maximowiczii* is not seen to any great advantage when grown in pots, and from its tall slender habit of growth it is not fitted for planting in an isolated manner, but a good clump in a nook between some shrubs shows off its distinctive characteristics to advantage, and forms a very showy early autumn feature. This Lily being commoner than *L. Leichtlini* and the bulbs of the two almost identical, it is frequently sold at the winter sales of bulbs as *L. Leichtlini*, and it is only after they commence to grow that the difference can be detected. It is also sometimes known as *L. Leichtlini rubrum*.—H. P.

#### CARNATIONS FOR WINTER FLOWERING.

THE article on Tree Carnations (pp. 200 and 207) induces me to make a few remarks, which I trust will be of interest to your readers. Carnations, if properly understood, can be had in flower all the year round. I do not of course mean that the same plants can be made to flower all that time, but a succession of them. Beyond doubt the most difficult period to have a good show of bloom is during the months of November and December. In November for the last two years I exhibited a group of choice Carnations in full flower, mixed with Ferns, at the Chrysanthemum shows held at Teignmouth and Plymouth.

Border Carnations should always be layered as early as possible, and it is not always easy for the operator to discriminate between the grass and the flower shoot, so he usually layers them all. A good many of these flower-shoots grow, and in course of time develop buds about this time. These layers, if carefully removed from the parent plant and potted up in good soil, leaf-mould and sand, will with careful handling grow on and flower for months in a house that is warmed just sufficiently to keep out frost, thus adding greatly to the Tree varieties, which by that time may or may not be in bloom.

In America it appears, from what I have read on the subject, the main object of the florist is to have a large show of Carnations for cutting during winter. Their principal shows are in winter, and the treatment of the plants is all directed towards that end. I should like to see an exhibition of this nature in England in December. The photographs that I saw of the blooms exhibited at the meeting of the American Carnation Society, which was held at Boston in February last, were certainly very fine. So impressed was I with the

report of this meeting, that I at once put myself into communication with a leading firm of florists in America, and directed them to prepare for me, for winter flowering, and ship to me in the autumn, a considerable quantity of such varieties as were considered the best Carnations in America at the present time. This was done, and the plants were grown on in pots and have just arrived per s.s. *Teutonic*. They have been repotted, and will, I trust, make a grand display under glass this winter in a conservatory that is just sufficiently warmed to keep out frost. Anyhow, such of them as I retain I intend to give a good trial to, as the number of varieties of winter bloomers is not so many but that we can welcome additions which I trust have come to stay. The names and colours are as follows: Lizzie Gilbert, scarlet self; Silver Spray, pure white; Helen Keller, variegated, white and pink; Bouton d'Or, orange yellow; Daybreak, light pink; Lizzie McGowan, fine clear white; Buttercup, yellow variegated; Uncle John, pure white; William Scott, pink; and Iago, whose colour I do not yet know. H. W. WEGUELIN.  
*Shaddon, Teignmouth.*

#### BEGONIAS AT LEWISHAM.

TUBEROUS Begonias are largely grown by Mr. H. J. Jones in his nursery at Hither Green, Lewisham, both under glass and in the open air. The season for those grown in pots is now past, but there was still an abundance of bloom in two large houses entirely filled with Begonias when we saw them recently. The outdoor plantations, however, were in fine condition and made a brilliant picture of gay colour. It is needless now to enlarge upon the merits of the tuberous Begonia as an open-air flower for summer gardens, as this is an accepted fact, and the flower is largely grown in many gardens. Although at first decried as of doubtful value by reason of certain natural characteristics of growth and blooming, the persistent efforts of florists have resulted in the elimination of these weak points, and they have given us a strain that does well in the open air. The strain that Mr. Jones is growing in his nursery, and of which we saw nearly 100,000 plants, is an admirable one in every respect, and in habit, profusion, quality and erectness of bloom, leaves nothing to be desired. There are here no named varieties, but the plants are rigidly selected in conformity with the essential points and classed according to colour, which is really all that is necessary so far as concerns Begonias for the flower garden. The plants all have a stout, sturdy habit of growth, and hold their flowers up well above the leaves. We noticed a great improvement in the yellow-flowered forms, which, formerly of a pale hue, can now be had in the richest orange and buttercup-yellow shades. In other self colours, pure white, pink, rose, scarlet and crimson, selections represented the tuberous Begonia in such perfect form, purity and richness of colour, combined with a habit best suited to open-air conditions of growth, that one wonders what further improvements or developments of the flower are possible.

**Sowing Cyclamen persicum seed.**—Although it may suit the wishes and convenience of market cultivators of Cyclamens to sow the seed in June or August, I do not sow mine until early in November. From this sowing the plants commence to flower in the early part of September and continue until the end of April. It seems to me a great waste of time and convenience to treat this Cyclamen other than as an annual, such satisfactory results being obtainable under this mode of management. Growing the plants in heat too long in the early summer months is not the way to have a satisfactory crop of blossom either from plants raised annually or by retaining the corms from year to year.—E. M.

**Cyclamen persicum.**—The article with coloured plate of the above in your issue of September 7 reminds me of a well-grown batch of Cyclamen

mens which I lately saw at the gardens of Nostell Priory, Wakefield, the Yorkshire seat of the Right Hon. Lord St. Oswald. I understood from Mr. Easter that the seeds were sown at the end of last July, the plants being kept slightly on the move all through the winter. They were eventually potted into 5-inch and 6-inch pots, and when I saw them they were occupying two frames at the back of a north wall, many of the plants measuring a foot across, with fine, bold, handsome foliage marbled and blotched in various ways. Seeds have been sown to supply plants for another year. The plants when finished flowering will be consigned to the rubbish heap.—T. T.

ORCHIDS.

ODONTOGLOSSUM GRANDE.

THE contour and general appearance of this well-known Orchid are well depicted in the accompanying illustration, but the spike from which

*Odontoglossum grande.* Engraved for THE GARDEN from a photograph sent by Mr. J. S. Moore, Wimbledon.

it was taken is not quite large enough to show the real capabilities of the plant. *O. grande* must be certainly reckoned as the finest autumn-flowering *Odontoglossum* in existence. It is a strong growing plant with deep green leaves and pseudo-bulbs growing very closely together. The flower-spikes are produced at the time the pseudo-bulbs are finishing their growth, being at first encased in a greenish sheath. The number of flowers produced on each varies from three to eight, the latter number not often being exceeded. Each blossom will measure from 5 inches to 6 inches across the petals, which, as well as the sepals, are of a bright yellow more or less heavily blotched with bright chestnut. The lip is yellowish white in ground colour with a few brown spots and markings, and the whole flower has a glossy shining appearance as though varnished. The flowers last from three weeks to a month in perfect condition, and no harm will accrue to the plants by their being retained provided they are healthy and well established. *O. grande*, when imported in good condition, is

one of the easiest of Orchids to establish, and I have frequently potted it up just as received except that it was carefully cleaned. The safest plan is to lay the plants for a time on a moist stage, placing them in pots as soon as they are plumped up and commencing to root. After they are established, it is a very easy matter to keep the plants healthy, the ordinary routine of cool house Orchids being all that is necessary. The pots should be just large enough to take them easily and good drainage must be given. A thin layer of rough compost consisting of three parts of peat to one of chopped Sphagnum Moss with a good sprinkling of rough pieces of charcoal or crocks is what the plants delight in, and while pressing this firmly enough to keep the pseudo-bulbs from moving, endeavour to have it as light and aerated as possible, the roots being somewhat larger than those of most other kinds. The summer temperature can hardly be kept too low, and the plants must at this season be heavily shaded,

*O. grande* being found growing naturally under these conditions. During winter, however, the plants like a little more warmth than is afforded such species as *O. crispum* and *O. triumphans*, and if no intermediate house is at command, the plants will be best arranged at the cool end of the Cattleya house. An abundant and constant supply of fresh air is an important detail in growing *O. grande*, the foliage under this treatment taking on a russetty look that indicates vigorous health, the flowers, too, being of better colour and having more substance than if the plants are grown in a very close house.

*O. grande* is more constant in its time of growing and blooming than most kinds, and usually rests awhile after flowering. During this period very little water will suffice for it, just enough to keep the bulbs plump, but while growing freely it requires an ample supply. Like all others, *O. grande* has its insect enemies, and these must of course be kept under by the usual means. I know of no other kind that is so attractive to slugs and small snails, and the closest attention is needed while the spikes are

forming. Small pieces of Carrot or Potato laid about near the plants sometimes lures them away, but usually these pests prefer the succulent young spikes and bulbs of the Orchids: so frequent examination with a light in the evening must be resorted to. Although a certain amount of variation exists in the flowers, there are not many named varieties of *O. grande*, the best possibly being *O. g. splendens*, *O. g. superbum* and *O. g. magnificum*. The first has purple markings in the place of the usual chestnut-brown, the two others being large and richly-coloured forms. The type is a native of dense forests in the neighbourhood of Guatemala, whence it was introduced by Mr. Skinner in 1839. R.

**Calanthe Veitchi.**—Now is the time to render assistance to the flower-spikes of this popular Orchid. At the base of the strongest growths the flower-spike can now be seen forming. By supplying copious doses of tepid liquid manure made from cow or sheep's manure, to which is added a handful of soot, the spikes will be greatly benefited.—E. M.

**Odontoglossum nævium.**—This singularly pretty little species is not seen so often as it deserves, for it is one of the most charming and free flowering in the genus. The flowers occur on nearly erect racemes and last a long time in good condition. They are rather starry, as it is termed, that is to say the petals are narrow, but the effect of the crimson and purple spots on the pearly white ground is very attractive. It delights in a cool, moist, and airy temperature all the year round, dense shade during the summer, and a position to catch every ray of sunlight in winter. It must not be overburdened with compost, and it is better to err on the side of small than large pots. Grow it in this way and keep it clear of insects and there need be no fear of the result at flowering time. It was found at a great altitude in New Grenada, so that the reason for cool treatment is at once apparent. The variety *majus* is larger and more highly coloured than the type, which was introduced in 1842.—H.

**Oncidium roseum.**—The long branching spikes of this Orchid closely studded with the pretty spotted flowers are very attractive. The plant has no bulbs and bears large leathery leaves only. Being a very free rooter it may with advantage be grown in comparatively large pots. Especial care must be taken with the drainage, covering this with a layer of rough Moss. The compost must consist of about equal parts of peat fibre and Sphagnum, and plenty of charcoal must be intermixed as potting proceeds. The leaves being very heavy, the plants must be supported by a few stakes. Care should be taken in autumn to allow plenty of light and air. This *Oncidium* thrives well in the Cattleya house.

**Odontoglossum tripudians.**—The free-flowering nature of this Orchid renders it worthy of a place, though the individual flowers cannot compare with those of some others, such as *triumphans* for instance. The habit is not unlike that of *Pescatorei*, which has been suggested as one of its parents. The flower spike is arching and simple with many flowers, which are bright yellow in ground colour, plentifully blotched and spotted with brown and usually a few crimson spots about the lip. This species is very variable and very easily grown, requiring a cool, moist house and a plentiful supply of fresh air all the year round. It is a native of New Grenada and was introduced in 1869.

**Cattleya Schofieldiana.**—This pretty and distinct *Cattleya* is in good condition with Dr. Turner, of Long Melford. In growth it is not unlike *C. guttata*, but the colour of the flowers is a rich yellow on the sepals and petals, these being plentifully spotted with crimson. The front of the lip is downy and of a rich purplish rose, the lateral lobes very pale rose fading to nearly white. This succeeds in a *Cattleya* house temperature and requires treatment similar to that recently re-

commended for *C. guttata*. It is a native of Brazil and was named in compliment to Mr. G. W. L. Schofield, who flowered it in August, 1882, a year after its introduction.

**Cypripedium selligerum.**—This striking and handsome Orchid is one of the older hybrids raised by Messrs. Veitch. The leaves are large, deep green and distinctly mottled. The flower-spikes are erect and bear three or more large flowers. The dorsal sepal is green at the base, becoming white at the apex with deep crimson lines. The petals are drooping, about 3 inches long, dull red with lines of purple and hairy on the edge; the pouch is large and purple. It requires stove heat and abundance of water at the roots while growing.

#### CATTLEYA LABIATA.

This well-known and handsome species is a striking instance of the fluctuation in value and rarity of Orchids. Not many years since the true *C. labiata*, or *labiata vera*, as it has been somewhat peculiarly styled, was possibly as rare as any kind in cultivation, but owing to the thousands of plants sent home since its re-discovery, it is at present cheap enough to be plentifully represented in all collections. Nor is it likely again to become scarce, even if no more plants were received, for it is one of the freest growing and most easily cultivated species known. Not only do the growths individually make good progress, but the number of eyes that break from the newly-imported pieces is remarkable. This being so, it is evident that if necessary the plant may be freely propagated. Several plants imported last season were noticed to be rather small in the bulbs, and the number of leads to each was not enough to make nicely furnished plants, so these were, as soon as they commenced to grow, notched about half way through the rhizome. Some growers may be inclined to the opinion that they should have been left until well established before checking them in this way, and really this would seem to have been a better plan to pursue, but in looking over the plants recently, not one has been found to have suffered in any way, and nearly every eye behind the notches has broken. The leading growths are certainly not so strong as could have been wished; in fact, they are no better than the back-breaks, but as this tends to balance the plants, it is so far satisfactory.

The best time to obtain newly-imported plants of this *Cattleya* is during the early spring months, they having then the season of growth before them. This is, of course, true of all Orchids to a great extent, but is of especial importance with these autumn-flowering *Cattleyas*. There is no difficulty in establishing the plants if the usual precautions are taken, the most important point being to gradually inure them to their altered conditions by not allowing too much heat, moisture, or sunlight at first. If fairly strong, many will flower the first season, while others will make good growths, but if the cheapest—because small and weak—plants are selected there will possibly be a few losses. But even with the latter there is always the chance of obtaining something unusual or novel, and this sometimes induces amateurs to purchase odd lots without paying much heed to their condition. The growths being well plumped up by the usual means and a little compost having been given, the plants should be kept rather warmer and encouraged to make a quick and vigorous growth. In the autumn this must be as well ripened as possible before the sun loses its power, and after this rested for the winter months. If all has gone well the plants will

need to be repotted during April or May of the next year, as it is a vigorous rooter and must have plenty of space. The roots if entwined much about the small pots in which they were first placed must be carefully broken, and the pieces of crocks with roots attached placed in the new pots. This is an operation that requires a deal more care than potting up a freshly-imported piece, for if the roots are roughly handled or torn from the sides of the pots, a very severe check will be caused. Small pieces are more easily managed than large ones, for where only two or three leads are to be brought into place, no great amount of care in disposition is necessary. Large plants with leads at varying heights are much more difficult. Some stout, yet neat, stakes will be necessary, and with the aid of these and some matting the leads will have to be pulled and tied in as regular a manner as possible, not leaving bare places in the centre of the plant if it can possibly be avoided. A difficulty will sometimes be found in getting the stakes to hold, the loose character of the compost accounting for this. Here a little copper wire may prove useful, first running a piece all round under the rim of the pot or pan and fastening the ends of the shorter wires to this; or if the perforated pans are used, a wire can easily be passed through these holes and made fast. After they are got into as good a shape as possible fill in all around with compost, using plenty of charcoal or crocks with the peat and Sphagnum. Bring this into contact with as many of the leading growths as possible; this will protect the roots from insects and cause a better growth than if these are emitted above the surface of the compost. At the same time avoid burying any eyes that are likely to break, or the ensuing growths will be spoilt, these often tending to make a plant well furnished in the centre.

No special treatment as regards heat and moisture is necessary for *C. labiata* when established, the ordinary *Cattleya* house routine suiting it admirably, the plant soon falling into a regular and constant habit of growing and flowering at the proper season. The typical flower is of medium size, with broad, well-formed spreading segments of a bright rose colour. The lip has an intense crimson blotch in front, bordered with rose, and the throat is richly pencilled and very beautiful. Naturally, among so many plants as have recently been imported there is a great variety of colour, and dozens of named forms have been described from time to time. But the great charm of *C. labiata* is its freedom of flowering at the dullest time of the year, no other *Cattleya* keeping up such a beautiful display during the present and two following months, where plenty of plants is grown this continuing right on up till Christmas. It is a native of Brazil, having first been brought to this country as far back as 1818, and being the first to flower, was the species upon which this most important and beautiful genus was founded by Dr. Lindley several years afterwards in compliment to the distinguished Orchid grower whose name it bears. H. R.

#### CYCNOCHES CHLOROCHILON.

The genus to which this plant belongs contains some ten or twelve species, to which the name of Swan Orchids has been given. The singular structure of the flowers has more to do with their popularity than any great beauty they possess. On the whole, *C. chlorochilon* is the most suitable for general cultivation, and produces a fairly good flowering return for the little trouble needed to grow it well. It is an upright growing plant, with pseudo-bulbs upwards of 1 foot in height

and somewhat thin foliage. The flowers occur on arching racemes, some varieties bearing from eight to ten rather small blooms, while in others the blossoms are larger, but fewer on the spikes. The sepals and petals are creamy white, the lip pure white, with a blotch of green in the centre. The column is about 2 inches in length, curved gracefully, and the pollen at the end makes a swollen rounded head. The plants commence to grow early in the new year, and this is the season for repotting. They like a strong compost, being rather gross feeders. Two parts of loam, one of peat fibre and one of Sphagnum Moss will grow them well if used in a rough condition over efficient drainage. Very little water will be needed at first, light dewings from the syringe being all that are necessary. The plants must have a light position in a warm, moist house and be shaded from bright sunshine. As soon as the young growths are starting the syringing must be discontinued, but a little more water will be required by the roots, which will by this time have become active. Nor must the plants be watered overhead at all after this, as the young growths collect it to their own detriment. By midsummer the flower-scapes will be showing and the growths approaching completion. Frequent spongings are necessary to rid the plants of the soft brown scale so frequently found upon this class of Orchids, using the sponge very carefully to avoid bruising or puncturing the leaves. After the flowers are past and the bulbs are quite matured the foliage turns yellow and drops off. The water supply must then be diminished, very little being needed while at rest. The winter temperature must not fall below 50°, or the pseudo-bulbs are liable to be attacked by spot, especially if the atmosphere is at all damp. *C. chlorochilon* is a native of Demerara, and was introduced in 1838.

#### TREES AND SHRUBS.

##### MANDEVILLA SUAVEOLENS.

I HAVE seldom had a more pleasant surprise than what came to me this morning when I perceived *Mandevilla suaveolens* once again looking in at my bedroom window, and not only so, but just about to break into glorious blossoming. Of course, this latter is only a slender reminder of what used to be, but any reminder at all under existing circumstances is of the greatest value to me. I should think that this magnificent climber has been where it is now in my garden for the last twenty years or more. It has braved several hard winters and stood many a storm, but I feared all through the beginning of this year and nearly up to midsummer that its course at last was run, and so also it seemed to be the case with three other specimens which I planted at a later date against the south side of St. John's Church. All four were cut down to the ground by the ruthless frost of last January and February—the main stem of my shrub had become so large that it had a girth of 2 inches or 3 inches, and the others were going on in the same way—but a bundle of dry sticks was all that seemed left to me of some of the greatest ornaments I possessed. Judge, therefore, of my surprise when a short time ago green shoots appeared from the bottom in three out of four cases. One, I fear, has gone hopelessly wrong, but the other three specimens of *Mandevilla* have reasserted themselves in a wonderful way, and they have done their duty well. The one I have in this garden has nearly managed to touch the eaves of my house, and what is more unlooked for than anything else, there will be just an umbel or two of its splendid white blossom, a reminder of the days that are over—a very strong presage indeed of returning victory and success in the days that are to

come. I am sure that if anyone had told me somewhere about midsummer that on the fourth or fifth day of September I should again have any measure of blossom from this glorious climber I should have expressed myself as incredulous about it to the last degree. There was no sign or apparent likelihood of any such thing, but when once the plant began to grow, it did so with the utmost vigour. It seemed almost to know that it had very hard work cut out for it this year, that it must not lose a minute of sunshine if it was to touch my bedroom window again, and when it had done so it signified its accomplishment of a very difficult feat by breaking out into smiles of the most captivating blossom that can be conceived. The lesson which may be learnt from it all is quite plain. This denizen of Chili, which has been so often consigned to the greenhouse and sometimes even to miseries of a worse description than that, which hates to be confined and very soon becomes the prey of red spider and other abominations of the same sort, will live and do well in the open border in such places as the Isle of Wight, and it will make one glad that trust was put in it to combat any adversity which might occur.

I believe that the shrub against St. John's Church, which at present shows no signs of life, was killed, not so much by the frost as by an encroaching Cotoneaster, which got too close to it and robbed it of the sunshine which it loves so well.

But let anyone think what the Isle of Wight and other places would be if *Mandevilla suaveolens* were as commonly grown as Myrtles and Passion Flowers are. As it is, nobody thinks of it, or if it is thought of, it is taken for granted that it is an altogether absurd speculation to go upon, and splendid possibilities are neglected in this and in similar parts of the world. I am quite certain that if anyone who is fond of flowers had seen the performance of my *Mandevilla* three or four years ago he would never have been contented to be without it for a day. I am presuming of course that he lives in some southern spot, for here it is perfectly at home, and though once in about forty years it must be admitted that it may be cut down to the ground, all that will happen is that it will get strength from adversity, and very soon it will be struggling upwards again in renewed health and vigour. My confidence in my favourite is immeasurably increased by recent, or rather present, experience. It did so happen that a few years ago—on the occasion of one of the last visits he paid to me—my old friend Canon Prothero saw this magnificent climber quite at its best. The southern side of my house was glistening with the profusion of semi-tropical blossom as white as the driven snow. One could have plucked bunches of *Mandevilla* from the wall and not have missed them in the least, and it need scarcely be said that his surprise was only equalled by his pleasure. He had too many other things to do to take much trouble about flowers, but he was certainly fond of them, and he liked to get hold of any good thing that came in his way. I have several times taken plants to his garden at Whippingham, which were then consigned to situations where they were certain to perish. But in the case of *Mandevilla* greater caution was taken. He let me have my own way, and we selected the very best spots we could find on the south side of Whippingham Church, good soil was provided for them, and we spent some little time a few years ago in planting two specimens of *Mandevilla suaveolens*, and giving to them just what they required. On the sorrowful occasion

of my dear old friend's funeral in October last we had to pass close to these beautiful things, which were so remindful of him and of the happy morning I passed in his company, and I was extremely glad to see that they were quite an exception to the general rule. Nothing could be doing better than they were doing at that time, and I hope that for many years to come they will continue to prosper. I have not seen Canon Prothero's successor of late, or I should have asked him at once how *Mandevilla suaveolens* got through last winter. But however it may have been in Whippingham Churchyard, and I hope and trust that it was all quite right there, I am sure that the climber which has managed to do so well in about seven or eight weeks, that it now looks in at my bedroom window again, is worthy of all admiration, and as it has got through the terrible ordeal of 1894-95, I have now the assurance that I shall never be without it as long as I live.

HENRY EWBANK.

**Spiræa Anthony Waterer.**—Since writing the note on page 138 concerning this *Spiræa* the colouring of the flowers has become as rich as last year, hence the fear expressed that it might be developing a tendency to revert to the normal type has proved to be unfounded, which I am indeed pleased to acknowledge, as it is such a beautiful dwarf flowering shrub that it would be a great pity if there was any liability to produce paler blossoms. The great heat and drought would appear to be answerable for the want of colour in the flowers, as after the copious rains experienced in the early part of August the blossoms at once improved in colour.—T.

## ORCHARD AND FRUIT GARDEN.

### BACK GARDEN APPLES.

My back garden is of the usual long strip description common to nearly all moderate-sized town houses, being about 120 feet long by 25 feet wide. The walls are covered on both sides with the best Gooseberries, which bear well and ripen in succession, those on the shady side lasting until August, while those in full sunshine ripen in June. There is a robust *Victoria* Plum tree three years planted, and also a healthy young *Hazel Pear*, but my main fruit crop consists of Apples, the trees of which have been planted twelve years and have cropped well for the past ten years.

The kinds are mentioned in their order of ripening: *Juneating* or *Jeumetting*, a small conical, yellow fruit, heavily streaked with red and heavily perfumed, makes a pretty dish and ripens early in July. This is followed by the *Irish Peach Apple*, a handsome fruit with a delicious aroma ripening in August, this being succeeded by the brilliant *Worcester Pearmain*, a very showy Apple of fair flavour.

The cooking kinds are *Keswick Codlin*, a free bearing and fertile cropper, and one of the very best of all early Apples for cooking. Every cottager with a bit of garden ought to have a couple of bush or dwarf trees of this kind. *Lane's Prince Albert*, *Early Strawberry*, *Duchess of Oldenburg*, *Lord Suffield*, *Barnack Beauty*, *Schoolmaster*, *Warner's King* and *Wellington* or *Dumelow's Seedling*, and the old *Striped Beaufin* are all worth a place, the two last-named being kinds that keep well into the new year.

An Early Prolific Plum (*Rivers*) and a *Fertility Pear* (*Rivers*) might be added to the most select collection, and if there is wall space

a *Green Gage* and a *Pond's Seedling Plum*, or if the soil be gravelly or flinty a *Moorpark* or *Breda Apricot* might be tried with advantage. Even in the midland counties, as in *Leicestershire*, *Rutland*, and *Northampton*, I have seen very fertile and profitable crops of *Apricots* grown on cottage and farmhouse walls, with their roots beneath a hard pebble pavement, but I notice that a gravelly soil seems to suit them best.

But *Gooseberries* and *Apples* are after all the best and most serviceable of all fruit trees for small gardens, or even for many large ones as well. At West Ham the other day I saw over a thousand fine healthy and fertile bush or dwarf *Apples* and *Pears* interspersed with standard *Pears* and *Plums*, and the crops were splendid as seen on the trees, or as packed in bushels, half bushels, and sieves ready for the market. These trees varied from three to eight years old, and had been thinned a little, but not snipped and pruned in the usual fatal manner.

Good healthy bush *Apples* on *English Paradise* stocks once well planted in deep rich soil, and then left untouched, soon repay the cost of planting, and where soil and climate are alike genial they very often form the most profitable of crops, even though they may not yield enough to buy the freehold of the land on which they grow. F. W. B.

**Plum Jefferson.**—I do not think this Plum is grown nearly so much as it deserves, as either for dessert or for cooking I do not think it has a rival. No Plum that I know makes such lovely jam as this, being preferable to that from *Green Gage*. As a cropper it cannot be excelled, not even by *Victoria*. Well-managed trees growing against an east wall never fail to give a full crop of handsome fruit without the trouble of thinning.—E. M.

**Kirke's Plum.**—This Plum has been very fine this season, the fruit being both plentiful and of large size, the flavour also being superb. I think, however, that *Kirke's* must be essentially classed as a wall Plum, as in the open it is a shy bearer. I met with it once in *Surrey* bearing freely in the open, but this is more the exception than the rule. The soil was gravelly and the tree a small standard. In this garden it is growing both against an east and a north wall, in each of which positions it bears freely, ripens up perfectly and carries a fine bloom. It is remarkable that a Plum will bear freely against a north wall, whilst in the open it is so shy.—A. YOUNG.

**Colour in Peaches.**—Rarely have *Peaches* against open walls been of better colour than this season—in fact, it is quite dense on several of the varieties, *Royal George*, *Stirling Castle*, *Crimson Galande* and *Diamond* being perfect. There are few fruits, if any, which repay the grower for the little extra labour bestowed upon them in the process of exposing than *Peaches*. Their marketable value is increased considerably and the flavour is improved. For market, many people gather the fruits too early. It is astonishing the benefit which follows leaving the fruits an extra two or three days upon the trees. If carefully handled and not left too long, of course, the fruits will carry well if well packed. I have seen fruits which were required for market literally torn from the trees. *Peaches* which are gathered thus will never ripen up of good flavour. I look over the trees every morning after the fruits commence to ripen. The fruits if left till far on in the day or until they have become heated are liable to show the least pressure.—A. YOUNG.

**Peach Dymond.**—This Peach is working its way surely to the front as one of the most reliable varieties in cultivation either for outside or indoors. Three or four years ago I called attention to its high merits, and subsequent experience has justified what I then stated. The fruits all swell

off evenly to a large size if the tree is not too heavily cropped. For outdoor culture against a south wall there could hardly be a better variety not only for home consumption, but for market as well, as good fruits fetch a good price.—A. YOUNG.

**Apple Duchess of Oldenburg.**—As recently referred to by Mr. J. C. Clarke, Duchess of Oldenburg is really a handsome and beautiful Apple; in fact, I doubt whether there is a handsomer Apple. In its outward appearance it bears some resemblance to well-grown specimens of that handsome American Apple, Washington. It is undoubtedly one of the best early Apples in cultivation. I have it in excellent condition this first week of September. It is best gathered and used or marketed direct from the tree and must be carefully handled. It is not altogether a soft Apple, but on account of its very clear skin it is apt to show bruises quickly if at all roughly handled. This Apple will succeed under any form of culture—either standard or bush—or even as a cordon along the margins of walks. From cordons I have had really very handsome fruit. Its brisk, spicy and refreshing flavour is most marked.—A. YOUNG.

**Peach Noblesse.**—This Peach is excellent this season on the open wall. It is really a fine season Peach, as in wet and dull seasons the growth is subject to mildew; it will not stand overcropping. Alexandra Noblesse, although a most excellent substitute, is not quite equal to the old variety in point of flavour, but the tree has a far better constitution. I have two very fine trees, on which I have never seen a speck of mildew or any aphid. Whatever some correspondents may say as to its being a shy bearer, it is not so in this garden, as always far more fruit sets than is required to remain for a crop.—A. YOUNG.

#### RASPBERRIES.

MUCH useful information has been given by several correspondents in THE GARDEN of late, and I am only induced to continue the subject by the impressions made on seeing the fine bed of Baumforth's Seedling at Hartham Park, Corsham, Sir John Dickson's Wiltshire residence. Under ordinary cultivation this variety is of dwarf growth—in fact, this is looked upon as a very great recommendation in its flavour—but under the special treatment of Mr. Welch, gardener at Hartham, it grows as rampantly as any of the many taller growing sorts. The garden here rests on a deep bed of stiff clay, so bad that other fruit trees can only be kept in good bearing order by somewhat frequent manipulation at the roots to prevent them penetrating into the clay, the surface being treated in such a manner as to tempt them to make fibrous, instead of strong tap roots. About one half of the large bed of Raspberries under notice was planted in 1892, the ground having been occupied by Black Currants. This was trenched 15 inches deep, plenty of manure and leaf-mould being worked in to that depth, the subsoil below it left untouched. In the spring they have a thick mulching of straw manure, which prevents summer drought penetrating to the soil below, and in a decayed state furnishes the requisite food for the roots on and near the surface. That the treatment suits the canes and crop there is ample evidence in their vigorous state and the large gatherings obtained, even in such an unfavourable season as the present one has been. A shortening of the bearing canes has been practised in the usual manner, but a few in opposite pairs were left this season to ascertain what might be expected of unpruned canes, and when I saw them in the height of the bearing season the weight of fruit on these pairs of canes was extraordinary, so much so that they could not be lifted without risk of breaking them. Temporary supports had to be erected to allow of the pickers passing beneath them. It is Mr. Welch's intention this season to leave two rows unpruned and erect an arched trellis to carry them, and the

crop, estimated on the last season's trial of the principle, must result in a very largely augmented one. This bears out what has been advocated recently in these columns, that the upper portions of the canes, which are commonly pruned away, are the best for giving heavy and superior crops, and certainly the question is one deserving of more general acceptance and adoption. Of the quality of Baumforth's there can be but one opinion—it stands unrivalled in its sweetness. Superlative is an undoubtedly fine variety, the berries assuming unusual proportions, the canes being vigorous and free fruiting, and with me continuing in bearing till late in the season. It is a variety that should be planted generally where fine fruits are appreciated. As a dessert fruit, however, Baumforth's grown as at Hartham is better, because it combines fine flavour with size of berry. W. STRUGNELL.

**Stocks for Pears.**—The non-success attending the culture of certain Pears is often erroneously attributed to the unsuitableness of the soil or locality, when the real cause lies in the stock on which the tree is worked. I have had strong proof of this lately in several gardens noted for fine Pears. Trees of certain Pears were bought in which matched each other exactly in rooting and general good appearance, yet, planted under the same conditions and receiving exactly the same treatment, some have done in every way satisfactorily, while others have signally failed, not perhaps to grow, but to fruit, clearly proving that the stock was at fault. I think more pains should be taken by nurserymen to find out the best stocks for the various sorts and then to graft on no other, as it is a serious matter for gardeners after watching and waiting to be thus disappointed, and that, too, through no cultural error.—J. C.

**Raising young Vines.**—Some people still appear to have a hankering for the strongest Vines procurable when planting new vineries or refurbishing old ones, but because they are strong and vigorous looking it by no means follows that they are either well rooted or ripened. One good Grape grower in East Anglia raises his Vines for planting from eyes put into heat not too early in the year, and grows them on without any bottom-heat, their final shift being into 6-inch pots. These in autumn are sometimes no thicker than a good-sized writing quill, but the wood is hard and well browned, the eyes prominent even at the base of the cane, and the roots healthy, hard, and wiry. These, when cut back and planted in firm borders, invariably go away freely, a colony of new fibres being formed by the time the stored-up sap is exhausted. Pot Vines grown in strong bottom-heat have nothing to recommend them beyond their size, which after all is but a secondary consideration. Nurserymen, however, have now for the most part abandoned the bottom-heat system, finding that gardeners generally are opposed to planting Vines so raised.—J. C.

**Market Grapes.**—I recently visited one of the Grape-growing establishments of the Messrs. Rochford at Ponder's End, Middlesex, and was quite astonished at both the weight and quality of the crops. The Vines are grown in long span-roofed houses of great width, but on account of five or six rows of Tomatoes in pots occupying the centres, not more than 8 feet or 9 feet of roof is allowed the Vines. Nevertheless in some instances they were carrying from fifteen to twenty bunches, some of which would grace any exhibition table. In some cases three and even four canes were taken from each Vine, this, perhaps, making up, so far as the formation of roots was concerned, for the shortness of the individual rods. I can scarcely believe that such Vines can last long under such a strain, but the aim of the Messrs. Rochford and all similar growers doubtless is to obtain the greatest possible yield of fruit in a minimum of time, and then to root out and plant fresh Vines. Liberal feeding is the rule, and at the time of my visit, the Grapes being far advanced in colouring, artificial manure was being conveyed in wheelbarrows, spread

somewhat thickly over the surface, and watered home with the hose. I have often thought it would do young men in training for private places good to spend a twelvemonth in one of these market establishments.—J. C.

## GARDEN FLORA.

### PLATE 1032.

#### DENDROBIUMS.

(WITH A COLOURED PLATE OF *D. DALHOUSIANUM* AND *D. DONNESLE*.)

THERE is no disputing the popularity of this fine and extensive genus of Orchids, one of the most generally useful in the whole family. The blossoms are in nearly every case very attractive, and the flowering return is ample, considering the amount of space the plants take up. The beautiful combinations of colour in some species and the rich self-yellow of others are included in as wide a range of colour and form as can be found in any one genus of plants, while the adaptability to culture of the majority is remarkable. Naturally, in so large and variable a genus different modes of culture are required. There are first the long cylindrical-stemmed, usually deciduous kinds as represented by *D. Pierardi* or *D. Wardianum*. These are best grown in baskets or small pans suspended from the roof, while the evergreen section, as *D. densiflorum* or *D. chrysotoxum*, are best reared in pots of varying sizes, according to the habit and vigour of the species. Again, the very dwarf-growing kinds, as *D. pulchellum* or *D. aggregatum*, thrive in many places on blocks more or less heavily dressed with Moss. The majority of Dendrobes like a strong, moist summer heat with plenty of sunlight, especially towards the end of the season, to ripen the growth and lay the foundation of a bounteous crop of flowers. The winter temperature need not be high, in fact 50° is ample for most of them, the principal exceptions being those that grow naturally through the winter months, including several of the nigro-hirsute group and also the deciduous *D. chrysanthum* and others. Propagation of many of the species may be effected by cutting the stems into lengths of 6 inches or 8 inches and laying these upon pans or boxes of Sphagnum Moss, this mode being frequently resorted to where the pruning system is practised. This consists in cutting away the pseudo-bulbs after growing, placing the plants in strong heat afterwards to induce a rapid growth, ripening this in due course and again cutting them off after flowering. It is not necessary here to go into the merits or demerits of this system, but it is one that cannot be recommended to beginners in Orchid culture, or indeed to anyone who is not prepared to give the plants the best of treatment afterwards. Many kinds, again, produce young plants upon or near the end of the stems, and advantage may be taken of these to increase the stock, while others can only be propagated in the usual way by dividing up the plants or taking off back breaks.

Many choice and beautiful hybrids have been obtained by crossing different species, and while some of these are fortunately plentiful, others are extremely rare and valuable. The good old *D. nobile* and *D. aureum* are the parents of several of these, including

*D. AINSWORTHII*, a striking and beautiful Orchid raised in the garden of the late Dr. Ains-

\* Drawn for THE GARDEN by H. G. MOON in Messrs. Sander's nursery at St. Albans. Lithographed and printed by Guillaume Severeyns.

1 LINDL. BUNYONIA ...  
3 L. BUNYONIA ...

worth, of Manchester. It closely resembles *D. nobile* in growth and partakes of its free-blooming character. The sepals and petals are white, the lip also white with a rich purple blotch in the throat. The variety *roseum* is similar to the type, but the whole flower is suffused with bright rose, the lip also deeper in colour. These are said to have both come in the same batch of seedlings in 1874.

*D. CHLOROSTELE* was raised by Sir Trevor Lawrence in 1887 from *D. Linawianum* and *D. Wardianum*, and is described as having the sepals white, edged with purple; the petals white, with a purple blotch at the tips; the lip amaranth in the centre, with a light yellow border and purple tip.

*D. LEECHIANUM* was raised in the garden of Mr. W. Leech by Mr. Swan in 1882. This has the same parentage as *D. Ainsworthi* and is somewhat similar, but has larger and deeper coloured flowers. The sepals are white, tipped with rich purple, the petals wavy and similar in colour. The lip has a blotch of deep crimson in the throat, and is also tipped with purple. The upper flower in the accompanying plate is

*D. DONNESLE*, a beautiful member of the *nigro-hirsutegroup* exhibited before the Orchid committee of the Royal Horticultural Society by Mr. Bradshaw, The Grange, Southgate, in March of this year, when it was deservedly awarded a first-class certificate. As will be seen, the segments are well thrown back as in *D. infundibulum*, while the blotch on the lip is similar to that of a variety of this Orchid (*D. i. Jamesianum*). It is said to be as strong in growth as *D. formosum*, and is a most desirable acquisition to this none too numerous class.

*D. DALHOUSIANUM*, the other species figured, is an Orchid requiring plenty of room for its full development, as the pseudobulbs not unfrequently attain a height of 6 feet or 7 feet. It was introduced from India in 1837, and named in compliment to the late Countess Dalhousie by Dr. Wallich. This plant requires a long season of growth in a moist tropical house and a short dry rest in a cooler temperature afterwards. Given these conditions it is as easily grown as *D. nobile*, and when once the plants are large enough they will bloom regularly and well every season, large plants with a dozen or more racemes being truly magnificent objects during the months of April and May, its usual flowering season. H. R.

**Princess Alice Stock.**—This Stock is probably the forerunner of a new race of a useful family of summer flowers. It comes into bloom in the same space of time as the ordinary Ten-week, but flowers continuously through the summer. It would appear to be intermediate between the Ten-

week and the East Lothian. It is a most useful variety to grow for cutting and equally valuable for creating a display in the garden during the summer and early autumn months.—J. C. B.

## THE WEEK'S WORK.

### KITCHEN GARDEN.

**HANDLIGHT CAULIFLOWERS.**—The sooner preparation for planting these is made the better, although the work will not in the majority of cases be carried out until the first or second week in October. If the plot selected for this early lot was thrown up roughly, as advised a month ago, it

protected plants of Cauliflowers, Cabbages and Lettuces depends on the way in which the beds are prepared for their reception in October. When these subjects are planted into light soil of considerable depth, lifting is invariably attended with much ball-breaking, the most useful fibres are destroyed, and a great proportion of the plants either runs away to seed or hearts in prematurely. The best way is to place a shallow frame on quite a hard bottom of ashes, afterwards covering this with a good thick layer of rotten manure, and finally laying on from 6 inches to 8 inches of good-holding bamy soil, firming it well when in a semi-dry condition. From such quarters the plants, if not too thickly planted, will lift with capital balls, a portion of the underlying manure still clinging to them, which will further nourish them when put into their permanent quarters. The frames being made ready, the lights should be left off day and night to get the soil thoroughly moistened and sweetened. When plants are pricked out into beds made up only a few hours previously, they always flag and suffer far more than when the root-run is firm and settled by standing a week or two.

**EARLY PEA BORDERS.**—It may sound somewhat strange to talk of this yet, but as in all gardens of any magnitude work becomes more pressing as soon as frost sets in, it is well to take advantage of a slack period to get in readiness any early borders, at least where Peas are sown in November. Where these borders have not a good natural fall towards the pathway, success in early Pea growing will be rendered more certain by adding friable soil in such quantities as will not only produce that, but secure also perfect drainage. Burnt refuse, potting-shed refuse, and the sweepings of walks and drives are all suitable for the purpose.

**PLANTING WINTER CUCUMBERS.**—If the directions given in former calendars have been attended to, plants of suitable winter varieties will now be fit for planting out. With a cleansed and disinfected house no fear need be apprehended of attacks by red spider, at any rate before the plants get well established. Presuming the house is furnished with sufficient bottom-heat pipes, all that will be needed is to three parts fill the bed or pit with good sound leaves, firm them well, surmounting this with mounds composed of good porous loam, rather light than otherwise, a free admixture of fresh horse droppings and rather large pieces of mortar rubble, the latter being necessary for securing a free escape of superfluous water from the roots. Do not build up the mounds too large to start with, as they can easily be added to as the plants extend in growth and emit new fibrous roots. Place a neat stick to each plant and water home, keeping the house rather close for a time and syring the foliage twice daily in sunny weather, giving the afternoon bath at 2 p.m. and sprinkling walls and pathways. Where evaporating pans exist they may well be filled with diluted liquid manure, the ammonia arising therefrom proving highly beneficial to growth, and acting as a check to red spider, the great enemy of winter Cucumbers. The laterals which are formed between the bed and the first wire of the trellis must all be pinched back to a couple of leaves.

**JANUARY FRUITING PLANTS.**—Seed may now be sown where convenience exists for growing a secondary batch for coming into bearing during January and February. As before stated, *Syon House* or *Telegraph* cannot be beaten for the purpose, and as soon as the seeds germinate raise the pots well up to the light and in a position free from draught. Be careful in watering, as the base of the stems is very prone to canker at this advanced date.

**TOMATOES FOR WINTER.**—Where these have been growing for some time in pits or frames removal to comfortable quarters must now take place. This is necessary not only to hasten on the crop, but to avoid an attack of mildew, which is apt to come upon young plants growing in cool quarters as the nights get colder. If the 6-inch pots are well filled with roots, a shift must be given into the fruiting pots, the best size being

*Dendrobium Dalhousianum*, to show habit of growth.

will now be in a sweet and wholesome condition, the soot and other insect-banishing ingredients then mixed having by this time become thoroughly incorporated with the soil. In the first place, tread firmly twice over, afterwards raking off all rough stones. Mark out the distances, allowing between each row of handlights a pathway of 2½ feet. Fix the line and throw out a slight cavity only just below the ground level and exactly the width of the handlights, afterwards placing these in order at a distance of 3 feet from one another. Leave the tops off unless very wet weather should set in, when it will be advisable to put them on crossways to prevent the ground becoming too saturated before planting time arrives.

**PREPARING FOR FRAME PLANTS.**—A good deal of the success, or otherwise, attending frame-

10 inches in diameter. Be careful to drain well and to add plenty of opening material to the soil, pot firmly, and give the plants a position close to the glass. Supply atmospheric moisture by means of sprinkled floors and walls rather than by overhead syringings, and as soon as the roots take hold of the new compost air liberally, though carefully, avoiding front air after the middle of October, as this is apt to produce mildew. Use clear water only until the leading growths have reached the top of the trellis, and indeed until a full crop of fruit has set, except in the case of weakly plants, which may have a little assistance two or three times a week. Pinch out all side growths and train on the one-red system.

**LIFTING POTATOES.**—All Potatoes except the latest crops in fields had better be lifted at once, or autumn rains will not only be liable to cause a secondary growth, but also disease. Store in dry, airy sheds, not too thickly, setting them over in wet weather. J. CRAWFORD.

### FRUIT HOUSES.

**EARLY PEACHES.**—The season is at hand when the grower can make selections for planting and attend to the wants of growing trees either by lifting to prevent gross growth or thinning out useless wood. The trees often suffer from want of moisture at this season and should get copious supplies. With the roots cool and moist there will be less red spider, and by retaining healthy foliage to the last the buds swell more freely. There should be no lack of moisture overhead during bright weather, and should red spider have obtained a hold, use sulphur freely two or three times a week when damping overhead. Now is a good time to do any stopping or thinning of wood on crowded trees, and if there is room for free extension, lay in freely the lateral growths from the leading branches. By this means a large space is quickly covered, and there is less gross growth than when severe cutting back is practised. Trees two or three years old may be made to cover a large space and bear heavy crops.

**LIFTING PEACH AND NECTARINE TREES.**—I briefly touched upon the importance of this some few weeks ago, and pointed out its value if done at this date. As the best time to lift is the end of September and early in October, there should be no delay in doing the work. Lifting is not only advised for strong or too vigorous trees, but also to prevent gumming, canker, and loss of branches. I am sure many trees are ruined by being starved, and disease follows loss of surface roots. By lifting now there need be no loss of crop the following year if the work is done while the trees are in full leaf. It sometimes happens the trees are much crowded, and may require to be planted in other positions. By removing now the trees will have had time to recover from the check and make new roots before the season of rest. With large trees more care is required to preserve as many of the fibrous roots as possible. It is well before interfering with the tree to be lifted to prepare the fresh site so as not to expose the roots a moment longer than is necessary. In all cases it is well to prepare a large hole for the tree so as to work round the roots, thoroughly packing the soil under the roots and making firm as the planting proceeds. Do not plant too deeply, as with the usual surface-dressings and feeding the border will be raised. Deep planting is often the cause of barren trees and canker. Trees of any size are best prepared the previous year if they have occupied the same position for some time. By so doing the roots will be in better condition and the trees will not drop their fruit the season after lifting. Every means should be employed to secure a large ball with ample roots.

**PLANTING AND SOILS.**—I attach much importance to the planting, no matter whether it be of home-grown trees or those sent from a distance. Though the Peach and Nectarine will do fairly well in diverse soils, there is a much better return by adding to the soil such materials as old mortar rubble, good turfy loam whenever it can be obtained, wood ashes and burnt refuse of any kind,

giving poor soils a liberal addition of bone-meal or small crushed bones in preference to a mass of animal manures. Drainage in some positions is equally important, and in cold late districts a free use of brick ends or rough rubble under each tree or growing on raised borders will give much better results. I have found these trees lifted and replanted in such a position not need further attention, except in the way of surface dressings, for many years. Should the borders get too high, now is a good time to take away the top soil quite close to the roots, and then give a covering of rich soil over the surface roots. I find excellent results are obtained when the roots have a hard-trodden path over them. In planting, the soil should be made as firm as possible, and young trees should not be planted deeper than when grown in their original quarters or when received from the nursery. After planting, do not attempt to train, merely support the tops, as there will be a certain shrinkage of the soil. In bright weather it will be necessary to syringe overhead daily to retain old foliage and prevent the new bark shrivelling. With large trees it is an easy matter to shade during bright sunshine early in the day. Keep the house closer for a short time to prevent cold draughts. By closing the front ventilators the house will be kept moist and new root growth will soon be active.

**SELECTION OF NEW TREES.**—It is well to choose those trees with sturdy growth in preference to those with a gross shoot or two and the other portion of the trees unevenly balanced. Trees free of blemish in the way of gumming, and with what are termed the extension branches fairly developed, are the best. For very early use, Waterloo, Amsden June, and Hale's Early are good. To follow these, Early Grosse Mignonne, Dagmar, Royal George, Noblesse, Bellegarde, Dymond, and for late use, Barrington, Princess of Wales, and Walburton will be found useful. The best Nectarines are Rivers' Early Orange, Early Rivers, Lord Napier (excellent for all purposes), Pine-apple, Hardwicke Seedling, and Humboldt. There are many others, but the half dozen named may be relied upon for cropping and quality.

**POT TREES.**—Of late years more attention has been paid to trees in pots, and even if it is not intended to grow these largely, a few may be made profitable when new houses are planted with permanent trees, as the pot trees will give a good return for two or three seasons till the house is well filled. If it is intended to get a full crop, trees that have been grown a season in pots should be obtained. These will be well set with fruit buds and ready for forcing, but for growing on, select the trees and pot just as the leaves are falling, plunging the pots in the soil to the rims for a time. If it is intended to grow a house of pot trees, a start should be made in the early autumn, as the trees potted now will fruit much better than when left till the early part of the new year. The trees for this work need more cutting out of weak spray and useless wood. By doing this work now, light and air are admitted, facilitating ripening of the wood. The trees if very robust can be shortened in when a firm growth is made. By growing pot trees there is a great gain in the way of variety. As a catch crop, I am a great advocate of pot trees, as if there is a demand for these fruits there is a good return in a short time. G. WYTHES.

**A Begonia garden.**—The beds on the two Grass plots near the Fern houses at Kew are a little garden in themselves, and a very gay one too in their present state, though they only contain Begonias. In most of the beds the small-flowered Begonias of the *semperflorens* race have been used, and with an excellent result. *B. semperflorens rosea* fills four corner beds, and the profusion of its rosy pink flowers is charming in contrast with the deep green leaves. The oblong intervening beds are filled with the large-flowered tuberous-rooted kinds. On the opposite plot are two round beds of the ordinary form of *B. semperflorens* and a fine bed of the variety named

Crimson Gem, a showy, handsome form, having bronzy green leaves and deep crimson flowers, its effect of leafage and flower together very telling. All these beds are very regular and well filled and make a pretty feature, quite different from anything in other parts of the garden, but they lack the finishing touch of a few fine-leaved plants to break up the apparent flatness.

## CHRYSANTHEMUMS.

### NEW CONTINENTAL CHRYSANTHEMUMS OF 1895.

To those who have watched the raisers of new Chrysanthemums in France, it must have appeared of late as if the unusual success of one or two eminent growers has acted as an incentive to a large number of lesser lights to do their utmost to introduce new seedlings into this country by way of competition.

All the new lists for 1895 are now to hand, and they form a little pile of some considerable dimensions compared with those of previous years. The numbers of supposed new varieties, which of late years have been on the increase, from established sources do not show any signs of diminution, for while we had only a few years ago seven or eight regular growers of seedlings, the total for the present season is probably nearer a score. Some of them are unknown to our importers, and their flowers have consequently no reputation in England. It seems, therefore, that out of nearly four hundred new French Chrysanthemums only a limited proportion is likely to find their way into the hands of our collectors, and so the list which is appended to this paper will merely contain such varieties as there is reasonable hope to believe will be seen in part at the trade exhibits during the autumn of the present year.

With respect to classification, a great hindrance to a free importation exists in the neglect of some of the French nurseries to adopt our method of classification. An omission to state to what section a new flower belongs brings an element of uncertainty into the choice of what novelties shall be purchased, with the frequent result that it is passed over for one where the information is definitely given, and which may perhaps be an inferior flower. Those growers, however, who know what it is to do business with English introducers are more careful in this respect, and consequently reap the benefit of their knowledge. It is not difficult to gauge the way in which popular taste still runs. By far the greater proportion of the 1895 novelties appear to belong to the Japanese and the incurved sections. There are scarcely any new Anemone or pompon varieties enumerated in the foreign lists, and the hairy-petalled varieties this season are less numerous than we might expect. These, however, as on previous occasions, will form the subject of a separate article.

All the well-known growers, such as Messrs. Délaux, De Reydellet, Lacroix, Calvat, Boucharlat and Crozy, appear to the fore, but there are others, such as Messrs. Chantrier, Ricard, Rivoire and Héraud, who will doubtless become better known as time goes on.

Last autumn the Chrysanthemum shows in France were probably unusually numerous, and many of the new seedlings were awarded prizes there which it would serve no useful purpose to record here because of the different standard set up by English growers. M. Calvat is the only raiser who regularly sends his seedlings to be adjudicated upon by the floral committee of the National Chrysanthemum Society, and last season he was exceptionally fortunate.

The question of nomenclature is one that always gives rise to much dissatisfaction, for there still appears to be an utter disregard of anything like organised method to prevent synonyms. Many of the names that appear in the following list will be recognised as having been used before, and nothing we can do seems likely to arrest it. When the French inaugurate a Chrysanthemum society

on the lines of our National Chrysanthemum Society or the American Chrysanthemum Society, there may be some hope, but until then there appears to be no chance of anything but additional confusion year after year. It is interesting to record that efforts are now being made to procure seed from Japan as well as to import all the best of the English and American seedlings. By this means the Continental stock will no doubt be improved, as the addition of fresh blood cannot fail to have a beneficial effect in the process of cross-fertilisation which is so largely practised by the French growers in their favoured climate:—

*Album Striatum* (Lacroix).—Japanese; white, striped violet-carmine.  
*Amiral Avellan* (Calvat).—Japanese reflexed; bright dark yellow, broad petals. First-class certificate N.C.S.  
*Annamite* (Boucharlat).—Broad petals, chrome-yellow, striped and speckled red.  
*Apollon* (Boucharlat).—Incurved; broad petals, coppery red, reverse old gold.  
*Babnet* (Lacroix).—Broad petals, brick-red, reverse old gold.  
*Baronne de Gunsbourg* (Reydellet).—Japanese; long petals, mauve, passing to white, tinted straw in the centre.  
*Baronne de Villefranche* (Bruant).—Carmine-rose, marbled white, tips white.  
*Bayard* (Calvat).—Japanese; rosy white, reverse white, tinted green at tips.  
*Belle Maure* (Crozy).—Broad pointed petals, pure mauve.  
*Bicoto* (Bruant).—Golden rose, reverse shaded white.  
*Blanche Crozy* (Crozy).—Broad pointed petals, pearly white.  
*Boule d'Or* (Calvat).—Japanese incurved; broad incurving petals, straw-yellow and dull red, dwarf.  
*Cactus* (Crozy).—Purple, dull red.  
*Cardinal Lavigerie* (Ricard).—Coppery red and dark red.  
*Cascade Tramesègue* (Chantrier).—Japanese; creamy white, tubulated.  
*Castelbat* (Chantrier).—Japanese; velvety red.  
*Chimboraco* (Chantrier).—Canary-yellow centre, brighter outside.  
*Célèbre Rénus* (Chantrier).—Japanese incurved; creamy white, edged rose.  
*C. Harman-Payne* (Calvat).—Japanese; large blooms, very long drooping petals, dark purple, spotted white. First-class certificate N.C.S.  
*Chamechaude* (Calvat).—Incurved; dark carmine-amaranth, reverse silvery, almost white, late.  
*Ch. Burdin* (Parent).—Japanese; broad petals, coppery brown, tipped gold.  
*Chevalier Noémy Boulet* (Délaux).—Japanese; broad petals, dark golden, shaded red.  
*Chrysanthémiste d'Evère* (Délaux).—Japanese; long drooping petals, amaranth-purple, centre silver-white, tipped gold.  
*Colonel Dressez* (Chantrier).—Bronzy red, centre and reverse golden.  
*Comtesse de Tournon* (Boucharlat).—Incurved; broad petals, white and rose, passing to rose at tips of petals.  
*Conseiller Forichon* (Bruant).—Velvety red, reverse silvery.  
*Côte d'Or* (Crozy).—Broad petals, yellow, reverse ochre.  
*Crépuscule* (Lacroix).—Japanese; outer petals semi-tubulated, carmine-violet.  
*Damase* (Parent).—Japanese incurved; cinnamon, tinted carmine-rose, centre carmine-violet.  
*D'Artagnan* (Lacroix).—Japanese; chestnut-red, centre lighter, slightly hairy at times.  
*Deuil du Président Carnot* (Crozy).—Tubulated, purple-violet-lilac.  
*Directeur Tissierand* (Calvat).—Japanese; ochre-golden yellow, centre dark crimson, striped yellow. First-class certificate N.C.S.  
*Dr. Chiron* (Parent).—Japanese incurved; red.  
*Dominateur* (Boucharlat).—Broad petals, light purple-red.  
*Duchesse de Grammont* (Reydellet).—Japanese; long, broad petals, very light rosy mauve.  
*E. Forgeot* (Forgeot).—Japanese incurved; amaranth-violet, reverse silvery white.  
*Etoile de Champrousse* (Calvat).—Japanese; bright orange-red, reverse golden yellow, early.  
*Elise Brice* (Délaux).—Japanese; carmine-amaranth-violet, edged silvery white, centre silver.  
*Enfer* (Boucharlat).—Velvety crimson.  
*E. Rosette* (Délaux).—Japanese; broad petals, bright yellow, lightened canary.

*Etincelant* (Lacroix).—Japanese; outer petals semi-tubulated, bright chestnut-red, reverse golden.  
*Exposition d'Arras* (Reydellet).—Japanese incurved; broad petals, orange, striped yellow, reverse golden yellow, passing to lemon-yellow towards the edge.  
*Exposition de Luon* (Crozy).—Broad, slightly recurving petals, bright purple-red.  
*Feu Américain* (Chantrier).—Incurved; globular flower, garnet-red, reverse old gold.  
*Fleur d'Ivoire* (Bruant).—Ivory white, globular flowers.  
*Frédéric Tardy* (Reydellet).—Japanese; long, rather broad petals, vermilion, passing to brown at tips and on the reverse.  
*Gabriel Delorme* (Parent).—Japanese; old red, early.  
*Ganymède* (Lacroix).—Incurved; resembles Baron Hirsch in form, but the colour is lighter, reverse golden.  
*Général Jacqueminot* (Crozy).—Broad petals, colour resembles that of the Rose General Jacqueminot.  
*Général Mauric* (Chantrier).—Rose on cream ground, tips lemon.  
*Guito* (Bruant).—Silvery light rose and amaranth.  
*Gustave Henry* (Crozy).—Broad goffered petals, purple-amaranth, reverse silvery at tips.  
*Hébé* (Lacroix).—Flesh-white, striped lilac in centre.  
*Heliotrope* (Délaux).—Japanese incurved; broad petals, rosy heliotrope colour, reverse silvery, tipped old gold.  
*Hémisphère* (Hoste).—Long petals, bright fiery red, reverse and tips gold.  
*Illumine* (Crozy).—Long petals, golden ochre and red.  
*Ingenieur Oddos* (Crozy).—Broad drooping petals, Adrianople red.  
*Ingenieur Parandic* (Crozy).—Broad cupped petals, dark carmine-rose, reverse silvery white.  
*Jean sans peur* (Boucharlat).—Tubulated petals, silvery violet, tipped dark purple.  
*Julie Beauthéac* (Lacroix).—Soft rose, reverse striped violet.  
*L'Aigle des Alpes* (Calvat).—Japanese incurved; crimson-red, reverse gold, broad drooping petals, early.  
*L'Améthiste* (Calvat).—Japanese incurved; dark violet, reverse silvery, broad incurving petals.  
*L'Echelé* (Calvat).—Japanese; crimson-red, reverse gold, long flat drooping petals.  
*L'Etendard* (Calvat).—Japanese; pure white, long drooping petals.  
*L'Hiver Fleuri* (Délaux).—Long broad petals, white, edged rose.  
*L'Yémén* (Chantrier).—Japanese; lilac, spotted lighter, reverse old silver.  
*La Garonne* (Lacroix).—Broad petals, rose, with cream centre.  
*La Muladetta* (Lacroix).—Japanese; long tubulated petals, pure white.  
*La Savoie* (Parent).—Japanese incurved; long broad petals, white and mauve, tinted lemon in the centre.  
*Le Fringant* (Lacroix).—Broad petals, dark chestnut-red, reverse golden.  
*Le Laveru* (Chantrier).—Japanese; globular flower, lilac on ivory-white ground.  
*Le Moucherotte* (Calvat).—Japanese incurved; brownish-red, reverse yellow, broad petals.  
*Le Mouné* (Chantrier).—Lilac, silvery reverse.  
*Le Pernus* (Chantrier).—Japanese; canary-yellow.  
*Le Puy Morent* (Chantrier).—Orange, centre old gold.  
*Le Renégné* (Chantrier).—Globular flower, old gold-yellow, shaded brick-red.  
*Le Savignac* (Chantrier).—Japanese; soft rose on a cream ground, petals edged bright rose.  
*Leon Bonquette* (Boucharlat).—Very broad petals, ivory white, striped purple.  
*Lesbie* (Chantrier).—Soft rose, almost flesh colour, reverse silvery.  
*Lucienne Bruant* (Bruant).—Japanese; rose, tipped white, centre lightened primrose-yellow.  
*Luttlou* (Chantrier).—Japanese; bright brick-red, reverse old gold.  
*Mme. A. Borneainé* (Hoste).—Semi-tubulated petals, pure white and pearly white.  
*Mme. Adrien Charreyron* (Bruant).—Light magenta, reverse tipped green and gold.  
*Mme. Albert Guiniez* (Rivoire).—Japanese incurved; light crimson, shaded purple, reverse old gold, broad petals.  
*Mme. Amélie Planchon* (Bruant).—Lilac-mauve, rose, striped and shaded pearly white.

*Mme. Antonin Bonnefous* (Hoste).—Incurved; broad petals, soft rose, reverse white.  
*Mme. Auguste Nouin* (Bruant).—Light red, reverse coppery yellow.  
*Mme. Camille Prost* (Crozy).—Carmine-mauve, reverse grey.  
*Mme. C. Champan* (Calvat).—Reflexed; rosy white, centre cream.  
*Mme. Ch. Grimbert* (Crozy).—Broad petals, bright carmine-rose, reverse silver.  
*Mme. Ch. Perrin des Isles* (Hoste).—Semi-tubulated petals, soft rose and cerise, striped white.  
*Mme. de Beauve* (Reydellet).—Japanese Anemone; guard florets white, centre white, tinted straw-yellow.  
*Mme. de Bringuère* (Délaux).—Japanese; long petals; pure white, centre cream.  
*Mme. Dreuillet* (Lacroix).—Incurved; rosy buff, centre straw-yellow, good form.  
*Mme. Drumont* (Crozy).—Broad petals, bright violet-mauve, reverse silvery.  
*Mme. Edmond Foy* (Bruant).—Drooping outer petals, red, striped yellow.  
*Mme. Etisa Paris* (Chantrier).—Japanese; drooping petals, pure snow-white.  
*Mme. Ervard* (Crozy).—Broad pointed petals, violet-rose.  
*Mme. Ernest Capitant* (Calvat).—Reflexed; red or dark old rose, reverse gold, broad flat petals.  
*Mme. Frédéric Humbert* (Reydellet).—Japanese; long, drooping petals, garnet-red, reverse bronzy-red.  
*Mme. G. Merlin* (Calvat).—Tubulated variety, long petals, creamy-white.  
*Mme. Hamont* (Reydellet).—Japanese incurved; globular flower, bright mauve-rose, reverse slightly silvery.  
*Mme. Henri Constant* (Reydellet).—Japanese; long petals, soft flesh-pink, centre cream.  
*Mme. Henri Mesnier* (Calvat).—Japanese; broad drooping petals, pure white, dwarf and late.  
*Mme. H. Martinet* (Délaux).—Japanese; broad, lacinated petals, rose-violet, tipped golden yellow, reverse silvery.  
*Mme. James* (Délaux).—Japanese; silvery white, lightened rose, reverse lilac-rose, centre cream.  
*Mme. Jane Lévy Alvarez* (Bruant).—Silvery white, striped rose, tipped garnet-red, reverse tipped gold.  
*Mme. Lawson* (Chantrier).—Incurved; ivory-white, marbled with rose.  
*Mme. Leyris* (Crozy).—Long petals, dark rose, centre lighter.  
*Mme. Louis Lacroix* (Lacroix).—Japanese; broad petals, centre ones incurving, soft rose, lighter reverse.  
*Mme. L. Rousseau* (Reydellet).—Incurved; bright dark purple, reverse white, slightly tinted rose.  
*Mme. M. Giroud* (Calvat).—Creamy white, centre yellow, tubulated petals.  
*Mme. Marguerite Réau* (Bruant).—Crimson-red, reverse light bronze.  
*Mme. Odier* (Chantrier).—Japanese; old gold on a fiery rose ground.  
*Mme. Paladhine* (Reydellet).—Japanese; long, broad, drooping petals, centre ones shorter, white, tinted straw.  
*Mme. Philippe Rivoire* (Boucharlat).—Japanese; ivory white.  
*Mme. H. de Rovira* (Rivoire).—Japanese; purple-rose, tipped flesh-pink, semi-tubulated petals.  
*Mme. Rézal* (Crozy).—Dark rose, shaded flesh colour and cream.  
*Mme. Rouvière-Houlès* (Lacroix).—Japanese; rose, lighter at tips.  
*Mme. Vincent Marchand* (Marchand).—Broad petals, light sulphur-yellow, centre mauve.  
*Madeleine Lemaire* (Bruant).—Light red, edged gold, base of petals golden yellow.  
*Mlle. Amélie Clerget* (Bruant).—Carmine-red, reverse silvery white.  
*Mlle. C. Chaltier* (Parent).—Japanese incurved; pearly white.  
*Mlle. Delimoges* (Reydellet).—Japanese; long, drooping petals, soft mauve-rose, centre tinted yellow.  
*Mlle. Dumas* (Parent).—Japanese incurved; broad petals, pure white.  
*Mlle. Louise Blache* (Hoste).—Soft lilac-rose, white centre.  
*Mlle. Louise Lestournel* (Chantrier).—Bright lilac.  
*Mlle. Marie Gautier* (Chantrier).—Japanese incurved; creamy white.  
*Mlle. Nini Pomel* (Chantrier).—Japanese; bright lilac-rose, reverse silvery.  
*Mlle. Renée Aussier* (Héraud).—Orange-buff, shaded gold, reverse pale yellow.  
*Mlle. Rouvière-Houlès* (Lacroix).—Incurved; long petals, flesh white, outer ones striped light violet.

*Mlle. Valérie Héraud* (Héraud).—Long petals, creamy white, shaded purple-violet on the edges of petals.

*Marie Louise* (Crozy).—Broad petals, flesh colour, passing to white.

*Marie Thérèse* (Délaux).—Japanese; centre dark crimson, broad petals of dark ochre-yellow.

*Marquise de Candolle* (Rivoire).—Japanese; broad petals, crimson-red, shaded purple in centre.

*Maurice Gajon* (Parent).—Japanese incurved; brownish red, reverse gold, outer petals drooping.

*Mélina Duchanel* (Crozy).—Broad petals, flesh-pink.

*Michèle-Ange* (Cotille).—Japanese; reddish golden yellow, tipped vermilion, shaded velvety purple.

*Misses Orenham* (Délaux).—Japanese; long petals, violet-rose, reverse silvery.

*Mgr. Jauffret* (Chantrier).—Japanese; bishop's violet, late.

*M. Camusat* (Hoste).—Japanese; dark velvety garnet-red, reverse flesh-white.

*M. Carniane* (Reydellet).—Japanese incurved; broad petals, light rose, reverse white.

*M. Catros Gérard* (Chantrier).—Old gold yellow, edged red, centre bright gold.

*M. Cabanès* (Calvat).—Japanese; soft lilac-rose, reverse silvery, broad petals.

*M. Chénon de Léché* (Calvat).—Japanese; old rose, drooping petals, dwarf. Commended N.C.S.

*M. Constant* (Reydellet).—Japanese incurved; long petals, dark vermilion, reverse coppery golden yellow.

*M. Ch. Delahousse* (Hoste).—Incurved; broad petals, dark amaranth-violet, reverse white, centre same colour.

*M. de Bruyère* (Délaux).—Japanese; broad petals, bronzy brick-red, centre old gold.

*M. Denay-Taillaudier* (Calvat).—Japanese incurved; red, with light bronze reverse, broad petals.

*M. Desblanc* (Reydellet).—Japanese incurved; globular flower, old vermilion-red, passing to straw-yellow, centre golden.

*M. Dreuillet* (Lacroix).—Broad petals, golden yellow, centre burnt sienna, dwarf.

*M. Dutil* (Délaux).—Japanese; broad petals, yellow, fumed and edged violet-red, reverse light canary.

*M. Ernest Ausset* (Reydellet).—Incurved; bright dark carmine, reverse and tips silvery light carmine.

*M. Eugène Henriquet* (Reydellet).—Incurved; globular bloom, bright vermilion, reverse golden yellow, passing to rosy white.

*M. Fernand Denis* (Ricard).—Globular flower, rose, shaded white.

*M. Fokkonba* (Carrière).

*M. François Pollet* (Reydellet).—Japanese; long broad petals, light magenta-rose, reverse white.

*M. Georges Jager* (Héraud).—Dull purple, shaded velvety violet.

*M. Gribaldo Nicola* (Hoste).—Bright poppy-red, petals edged yellow, reverse golden.

*M. G.-H. de Clermont* (Calvat).—Japanese; brownish yellow, striped red, long petals.

*M. H. Vanderlinden* (Calvat).—Japanese; light yellow, long petals.

*M. J. Ginet* (Calvat).—Reflexed; carmine-amaranth, reverse silvery, broad petals, early and dwarf.

*M. Lawson* (Chantrier).—Japanese; bright violet.

*M. Léon Dabit* (Calvat).—Japanese; bright carmine-lilac, reverse almost white, spotted white, dwarf.

*M. Léon Grosjean* (Délaux).—Japanese; silvery white and violet-rose.

*M. Louis Neyret* (Reydellet).—Japanese incurved; long broad petals, dark carmine-rose, reverse silver.

*M. Marty* (Chantrier).—Creamy white, centre edged bright lilac.

*M. R. Ballantine* (Calvat).—Japanese; carmine-lilac, reverse silvery, very long petals, early. First-class certificate N.C.S.

*M. Rivard* (Ricard).—Long petals, white.

*M. Rivière-Houles* (Lacroix).—Brownish red, reverse old gold, incurving petals.

*M. Romzer* (Héraud).—Semi-tubulated petals, golden bronze, tipped velvety red.

*Mrs. H. J. Jones* (Calvat).—Japanese incurved; pearly cream white, tinted rose and yellow, broad petals. First-class certificate N.C.S.

*Ninette* (Crozy).—Broad petals, dark purple, almost black.

*Paul Bruant* (Bruant).—Japanese; light red, reverse light bronze.

*Péte de Mandoué* (Calvat).—Japanese incurved; dark golden yellow.

*Pierre Souyeu* (Chantrier).—Flesh colour, marbled with rose, lemon centre.

*Platou de Tech* (Chantrier).—Japanese; sulphur-white.

*Pluton* (Lacroix).—Japanese; velvety dark blood red, reverse brick-red.

*Préfet Albert Delpech* (Délaux).—Japanese incurved; long petals, dark crimson, centre old gold.

*Président Demoy-Taillaudier* (Reydellet).—Japanese incurved; broad petals, light mauve, passing white, centre yellow.

*Président Carnot* (Calvat).—Japanese; yellowish buff, reverse paler, long petals, dwarf and early.

*Président Léon Say* (Calvat).—Japanese incurved; bronzy yellow, reverse golden. Commended N.C.S.

*Président Reverdy* (Bruant).—Bright yellow, centre golden.

*Professeur Lachmann* (Calvat).—Japanese incurved; amaranth, reverse silvery, broad petals. First class certificate N.C.S.

*Professeur Mathieu* (Reydellet).—Japanese; flat petals, Bordeaux red, passing to old rose at the tips.

*Ratapail bicolor* (Crozy).—Anemone; long petals, brick-red, suffused ochre-yellow.

*Reine Béatrix* (Chantrier).—Japanese; dark lilac, marbled with white, reverse light lilac, dwarf.

*Reine d'Angleterre* (Calvat).—Japanese reflexed; mauve with silvery reverse, drooping petals. First class certificate N.C.S.

*Rosette* (Chantrier).—Japanese; bright lilac, approaching rose, tips white, reverse old silver.

*Rosériste Lévêque* (Crozy).—Broad petals, magenta-amaranth, reverse rose, tipped silver.

*Saturne* (Lacroix).—Incurved; bright red, reverse golden, good form.

*Secrétaire-Général Delaire* (Calvat).—Japanese incurved; old rose, reverse straw yellow, lightened rose, dwarf.

*Sénateur Sithol* (Héraud).—Broad petals, golden red, rosy reverse.

*Sœur Marcelina* (Chantrier).—Colour rosy flesh.

*Soleil de la Tronche* (Calvat).—Golden yellow and reddish brown, dwarf.

*Souvenir Ch. Roissard* (Parent).—Japanese; purple-violet, reverse silvery, broad petals.

*Souvenir de Chambéry* (Délaux).—Anemone; purple-amaranth, tubes yellow.

*Souvenir de l'Oséaie* (Ricard).—Magenta light violet, striped white.

*Souvenir de Jules Richard* (Lacroix).—Japanese; long tubulated outer florets, flesh-white.

*Souvenir de M. Castagnet* (Chantrier).—Old gold yellow, edged brick-red.

*Souvenir de Mme. Bouteux* (Chantrier).—Japanese incurved; flesh-pink, reverse silvery white, tipped lemon.

*Surprise* (Calvat).—Japanese; carmine-amaranth, reverse silvery, drooping petals, early and dwarf.

*Surpasse Mars* (Lacroix).—Pure yellow, colour very bright, a strong grower.

*Superbun* (Boucharlat).—Broad petals, pure violet, tipped silver.

*Tendresse* (Lacroix).—Broad petals, rosy white, cream centre.

*Triomphe de Marthe Bocher* (Chantrier).—Snow white.

*Triomphe de Mlle. Chatenay* (Chantrier).—Japanese; cream and flesh-pink.

*Vainqueur du Dahomey* (Crozy).—Purple-red, reverse golden ochre.

*Valée Albarès* (Chantrier).—Japanese; old gold, passing to coppery yellow.

*Vesta* (Lacroix).—Outer petals flesh white, edged violet, centre salmon-rose.

*Vice-Président Vieuot* (Crozy).—Tubulated petals, dark violet-amaranth, reverse tipped silver.

*Victor Bouteux* (Reydellet).—Broad pointed petals, garnet-red, passing to brownish red, reverse bronzy yellow.

*Viticulteur Veyrat* (Parent).—Japanese; fiery red, broad petals, spotted and tipped gold.

*Voleau* (Lacroix).—Long petals, velvety blood-red, reverse tipped old gold.

C. HARMAN-PAYNE.

*Chrysanthemum Mrs. J. R. Pitcher*.—This early-flowering Japanese variety is deserving of some attention where pure white blossoms are in request. The flat petals are nicely formed, exhibiting no roughness whatever, but a perfectly smooth surface, quite suitable for employment in the making of wreaths and such like.—E. M.

*Chrysanthemum Mme. C. Desgrange*.—Although at all times useful, especially for the filling of vases, this early-flowering Chrysanthemum has not been so good out of doors this season as it was last year. The long-continued

dry weather experienced directly after the plants were put out was not favourable to early progress. This, coupled with the continuously cold, showery weather early in August, was again most objectionable to that steady progress which results in that vigorous, yet firm growth which is so desirable in the production of a full crop of well-formed blossoms. Where the soil in which the plants are growing is heavy and retentive in character, a continuance of showery, cold weather acts injuriously on the foliage, causing it to die for some considerable distance up the stem. A retention of healthy leaves goes a long way to produce blooms of desirable quality.—E. M.

#### SHORT NOTES.—CHRYSANTHEMUMS.

**Early Chrysanthemum M. Dupuis**.—This is a very useful sort to flower in the open. It is dwarf and exceedingly free-blooming. The flowers are of medium size and of a bronzy yellow colour. It belongs to the Japanese section.—H.

**Chrysanthemum Souvenir de Petite Amie** is a welcome addition to the list of dwarf varieties. Plants barely 2 feet high are crowned with very promising buds and clothed with sturdy foliage to the rim of the pots. It is pure white, in form not unlike *Avalanche*, and I think it will ultimately replace that popular kind.—H.

#### AUGUST IN SOUTH DEVON.

DURING the month of August the temperature has been rather under the average, the mean for the last nineteen years being 61.5°, while that for the past month was 60.1°. The lowest temperature on the grass (44.2°) was registered on the 25th, while the highest reading in the screen was 70.4° on the 19th and 30th. The rainfall, although the first thirteen days of the month were wet, was slightly below the average, being 2.78 inches against a nineteen years' average of 2.86 inches, and less than that of August, 1894, by 0.53 of an inch; while the phenomenal rainfall of August, 1891 (6.85 inches, with 21 wet days out of the 31), surpassed it by no less than 4.07 inches. During the past month rain fell on sixteen days, the largest amount recorded on one day being 0.66 of an inch on the 10th. From January 1 till September 1 16.55 inches of rain have fallen, against an average of 20.96 inches and 22.50 inches in 1894.

The sun has shone for 188 hours exactly, against a yearly average of 187 hours 40 minutes, and 156 hours 35 minutes in August, 1894. From January 1 to September 1 1430 hours 30 minutes have been registered against 1208 hours for the same period in 1894. The month has been remarkably windy for August, the total horizontal movement of the wind being 7110 miles, the highest velocity being attained on the 27th, between the hours of 1 p.m. and 2 p.m., when the rate reached 29 miles per hour. On twenty-six days the wind has been southerly or westerly and on five days north to east.

The garden, aided by the rain at the commencement of the month, well retained its freshness. The scarlet *Lychnis chalcidonica* broke out into a second flowering, while the herbaceous *Phloxes* (dark red, white, salmon-pink, and white with claret eye) in large masses mingled with the tall white spires of *Galtonia candicans* and the vivid scarlet and gold of the *Torch Lily's* heads of blossom.

Of Lilies but four varieties have been in bloom during the month, without counting *L. chalcidonica*, which began to bloom in mid-July and is still continuing its display of shining red flowers into September. Of the four, *L. auratum* is perhaps the most striking. Some years ago I procured a batch of home-grown bulbs, for which a bed was specially prepared and each bulb carefully cased in sand. Not being particularly pleased with the appearance of the bulbs in question, I wrote to the consigner on the subject, and about Christmas received from him a small lot of imported bulbs, which, being of the opinion that importations usually failed after the first year, I planted in ordinary garden soil without taking any

special precautions for their welfare. The home-grown bulbs flowered feebly the first season, and have since given no sign of their existence; the imported ones bloomed tolerably at their first flowering, and have increased in beauty with each succeeding year. Some have the ordinary yellow band, some the red band, and one is virginale, the white variety, while two have proved to be the white-petalled variety called by nurserymen *platyphyllum*. The stately *L. superbum* has also been an object of great beauty, its tall stems and pyramid of purple-spotted orange flowers being exceedingly effective. It is grown in a partially shaded and wholly sheltered bed, the soil of which is peat, and is plentifully supplied with moisture during the growing season. *L. tigrinum splendens* and *flore-pleno* have been good, and both varieties are easily increased by the bulbs which are formed at the axils of the leaves. The Bermuda Lily (*L. Harrisii*), growing by the water, has also been a success, its long white trumpets hanging gracefully over the streamlet. The yellow Paris Daisies have become large bushy plants by August, and covered with their pale sulphur stars are exceedingly decorative in the garden and admirably adapted for affording a lasting supply of cut flowers, as they bloom without intermission until cut down by the frost. The *Tropeolums* have been at their best, *T. canariense* covering an old *Aucuba* bush with its bright yellow blossoms, while *T. speciosum*, which after many trials seems at length to have established itself in the garden, has threaded through a climbing mass of *Eccremocarpus scaber*, whose orange-red flowers are rendered dull in comparison with the vivid scarlet of its brilliant blooms. *T. tuberosum* rarely begins its flowering season before the latter half of the month, but when in full bloom is a beautiful sight with its long-stalked scarlet and yellow blossoms showing effectively against the thick background of lobed leaves. This *Tropeolum* will often grow 10 feet high in the course of the summer, and is seen at its best when rambling over climbing Roses in graceful festoons; it increases very rapidly, one tuber often producing as many as fifty in a year. A good variety of *T. Lobbianum* has been planted by the house, and, being a rapid climber, has mingled its scarlet blossoms with the white clusters of a *Solanum jasminoides* that has already reached the eaves. In a low-lying portion of the garden *Gunnera scabra*, varieties of the *Acanthus*, *Cannas*, *Ricinus Gibsoni*, and *Zea variegata*, backed by Bamboos and Arundos, with a tall specimen of *Aralia spinosa* standing Palm-like above the lower growing fine-foliaged plants, afforded a beautiful picture with their almost tropical outlines and restful shades of green. In the wild garden, a corner, in which the white bells of *Galtonia candicans* rise from out a large clump of *Salvia patens*, mingled with which are bronze-leaved plants of the *Ricinus*, is exceedingly effective. From another mass of the blue *Salvia* tall spikes of *Lobelia cardinalis* tower nearly 5 feet high. The white Japanese Anemones, which have been smothered with their chaste golden-anthered flowers, have attained a stature of over 5 feet 6 inches, and the Golden Rod has associated its yellow panicles with the flower-wands of tall blue Monkshoods, which have been in bloom, more or less, since the spring. There is a lavish display of yellow in the herbaceous border during August, the perennial Sunflowers, *H. multiflorus* and the double variety *Soleil d'Or*, together with *H. rigidus* and their large annual relative, as well as *Rudbeckia Newmanni*, *Coreopsis lanceolata*, and the last blooms of *Alstroemeria aurea*, making the chief note of colour in the garden a golden one, whilst scarlet is supplied by the *Zinnias*, *Pelargoniums*, tuberos *Begonias*, and the brilliant *Gladiolus bronchleyensis*, sheaves of many-flowered spikes of the latter blooming amongst the sweet-scented *Nicotiana*. The breadths of *Salpiglossis* were even finer than in July, and the pale blue masses of *Agathaea celestis* supplied a colour rare at the time, and only to be found by the water-side, where in the shade the water Forget-me-not still blossomed. The orange-scarlet Mont-

bretias, in constant request for indoor decoration, have flowered equally effectively in the open and in the shady spaces of the wild garden, while of other flowering plants, the Ivy-leaved Geraniums, Lavateras, blue Cornflowers, white Antirrhinums, the white Galega, *Chrysanthemum maximum*, *Tradescantia virginica*, white and crimson Clove Carnations, and in the rockery, *Plumbago Larpenæ* and many *Mesembryanthemums* may be mentioned, the latter, however, not taking as kindly to the heavy soil as to a lighter and more friable compost, a vermilion variety that I procured at the Cape persistently refusing to flower. Large bunches of *Hydrangea hortensia* have been, and still are, a mass of blossoms ranging from pink to light blue, and the Cactus Dahlias, *Juarezii* of the older varieties, and *Lady Penzance*, *Delicata*, and *Matchless* of the newer, have been much admired. Tea Roses, although attacked by mildew, have continued to flower well, and no day has elapsed since the commencement of May that a basketful could not have been gathered. Two Roses that are especially noteworthy at the present time are the copper Austrian Brier, that is flowering for the second time, and the single white Macartney, which when arranged together make a most charming contrast. The Sweet Peas are in the zenith of their glory, the newer kinds being certainly a great advance both in colour and size. When used largely for indoor decoration the varieties should be grown separately.

S. W. F.

## FERNS.

### STRONG-GROWING HYMENOPHYLLUMS.

THE culture of Hymenophyllums is generally, but erroneously, considered difficult, yet when placed under favourable conditions they grow as well as any other Ferns and with much less attention than most plants require. If we except two handsome species, viz., *H. pulcherrimum*, from New Zealand, and *H. fuciforme*, from Chili and Juan Fernandez, we find that all the Hymenophyllums known to this day are of creeping habit and provided with shallow-rooting rhizomes, which, contrary to those of *Trichomanes*, are smooth and of a wiry nature, delighting in growing on the surface of a rock, or a piece of sandstone and running under the Moss which covers it. Most of them, if not all, are natives of climates naturally cool and humid, growing where they are permanently subjected to the influence of shade and moisture, and also a comparatively cool temperature. The most satisfactory results of artificial cultivation of Hymenophyllums in accordance with their growth under natural conditions are shown by the fine specimens in the ferneries of Messrs. J. Backhouse and Son, of York, some plants from which have from time to time been shown in our London exhibitions, when they never fail to receive from the public the attention which they richly deserve.

Although their foliage is apparently of a delicate nature, Hymenophyllums are particularly well adapted for growing in Fern cases in the dwelling-house. We are here forcibly reminded of the plants of *H. demissum* fully 3 feet through which were grown by the late Mr. J. Cooper Forster in the north windows on the staircase of his house in Upper Grosvenor Street, where they formed immense masses of fronds, retaining their vitality for several years. The same may also be said of the magnificent specimen of *H. pulcherrimum* which was grown in a window case and exclusively in a cold room by Mr. J. F. Marchant, of 59, Berners Street.

Hymenophyllums, like *Todeas* and *Trichomanes*, require but little light, and a great depth of soil is unnecessary. As has been

stated, they luxuriate in constant moisture, but this should be produced more by means of condensation than by mechanical waterings, as the species with hairy or woolly foliage greatly suffer from being wetted overhead. The compost in which they delight is one composed of about equal parts of sandy peat, chopped sphagnum, and small pieces of sandstone, with an additional sprinkling of coarse crock dust. Such a compost is usually of such a light and permeable nature, that it cannot become sour through the accumulated moisture from the repeated waterings which may be necessary to produce condensation. Their propagation is usually effected by the division of their rhizomes, which operation is safe enough if a little attention is paid to the subjects operated on, but it is one requiring a little patience, as in a young state these plants grow very slowly.

*H. CAUDICULATUM* (here illustrated) is undoubtedly one of the most striking, as also one of the handsomest, of cultivated Hymenophyllums. As is the case with nearly all the plants belonging to this most interesting genus, its remarkably elegant fronds, of a very transparent nature, are produced from thin, wiry rhizomes running on the surface of the ground or on a decaying piece of Tree Fern, on which the plant may be growing. They vary from 6 inches to 18 inches in length and from 3 inches to 4 inches in width, and are broadly winged from their summit almost to their base. Their numerous divisions, and also to a certain extent their extremities, are furnished with a tail, which character has suggested the specific name of *caudiculatum*. Although a native of Chili, Peru and Brazil—where it is found growing naturally among decaying vegetable matter or on mossy trees—it thrives under cool treatment, and it is most gratifying to record that a plant of it in Messrs. Veitch's nurseries at Chelsea, having come through the rigours of last winter and been subjected to a long period of severe frost, has this season produced some excellent growths and preserved all its older fronds.

*H. CRISPATUM*—a very distinct plant, a native of Tasmania and New Zealand, where it is frequently found clothing the stems of Tree Ferns—is readily distinguished from nearly all other species through the distinctly crisp wing which is peculiar to the margins of the stalks of its erect fronds, which are 4 inches to 8 inches long, dark green, smooth, and three times divided nearly to their midrib into narrow, blunt segments, of a very transparent nature. It is said to be found also in Nepal, Ceylon and Luzon.

*H. DEMISSUM*.—This species, which is probably the most effective of the whole genus, and also the easiest one to grow, has a very wide range of habitat, being found in New Zealand, Fiji, Java, as well as in the Philippine and adjacent Polynesian Islands. Wherever any attempt at growing Filmy Ferns is made it is sure to be found. Its finely-divided fronds (6 inches to 12 inches long and 3 inches to 4 inches broad) are borne on firm, upright, wingless stalks of a wiry nature. The lively green colour peculiar to them when they are young turns to a deep dark green with age, and the plant deserves special attention at the hands of the cultivator on account of its vigorous habit and good constitution.

*H. DILATATUM*.—This is the largest growing and also one of the noblest-habited plants belonging to the genus. Its beautiful and extremely translucent fronds, of a pale green colour when young, are particularly graceful, the weight of their broad leaflets causing them to droop in an elegant manner. They are produced from a slender creeping rhizome, and are three times divided nearly to the midrib: their length, exclusive of the stalks, varies from 6 inches to 12 inches or more, and the stalk of their leafy portion is winged throughout, the wing being quite flat. It is found wild in the Samoan, Fiji, and other Polynesian Islands, also in New Zealand and Java, where it may be seen growing among Moss and decaying vegetable matter, and also on the trunks of dead

trees, especially of those lying in a horizontal position in close proximity to the water.

*H. FLABELLATUM*.—To the casual observer this lovely species, known also as *H. nitens* and *nitidum*, may appear simply as a variety of *demissum*. It is, however, totally distinct from it, and is very variable in size, compactness, and degree of elongation of its fronds, which in either in a young or in an old stage are of a peculiar glistening, bright green hue. According to the form, the fronds are from 4 inches to 15 inches long, including their round wiry stalks; they are divided three times nearly to the midrib, and somewhat resemble those of the popular *demissum* in outline, but their pinnae, instead of being smooth, have a

the general appearance of *H. caudiculatum* from its light green colour and prettily undulated nature; but its handsome fronds, which are produced in great abundance, attain much larger dimensions and their pinnae are not tailed like those of *caudiculatum*, and the wing along the midrib is so conspicuous that in well developed specimens it measures in the leafy portion a quarter of an inch in breadth.

*H. FUCIFORME*.—Unlike most other members of the genus, this handsome species, which ranks among the strongest-growing kinds known, is devoid of slender rhizomes. It is a native of Chili and Juan Fernandez, where it is found growing on trunks of trees in shady woods. Its upright-

and New Zealand. Its finely-divided fronds, 3 inches to 10 inches long, 2 inches to 3 inches broad, are borne on slender, wingless stalks 2 inches to 3 inches long, and the stalk of their leafy portion is usually only narrowly winged above. This species does not require such a close atmosphere as most other kinds; the most airy place in the house suits it best. On account of the propensity which its exceedingly slender, wiry rhizomes possess of making their way through partly decayed vegetable matter and also on account of the elegantly arching character of its fronds, it is one of the best kinds for growing on Tree Fern stems or on blocks of wood.

*H. FULCHERRIMUM*.—The lovely fronds of this

*Hymenophyllum caudiculatum*. From a photograph by Miss Willmott, Warley Place, Essex.

crisped appearance, produced by a contraction which is natural to them.

*H. FLEXTOSUM*.—This handsome and elegant species, with beautifully crisped and undulated foliage, somewhat resembling that of *H. crispatum*, is a native of New Zealand. Its broadly-pear-shaped fronds are larger and more finely divided than those of that species, being from 10 inches to 12 inches long and borne on slender, distinctly winged stalks; they are four times divided nearly to the midrib and furnished with narrow and undulated segments.

*H. FORSTERIANUM*.—A very free-growing plant, native of Brazil, whence it was accidentally introduced among some Cattleys. It has somewhat

growing fronds, of a glaucous colour and 1 foot to 2 feet long and 4 inches to 6 inches broad, are borne on strong erect stalks, narrowly winged above and round below; they are produced from thick, short decumbent rhizomes which have all the appearance of crowns. Their lower segments are two or three times forked.

*H. POLYANTHUS*.—This is probably the most cosmopolitan of all known *Hymenophyllums*, it being very widely distributed and found in a wild state: in West Tropical Africa—Mauritius and Madagascar; in America—from Cuba and Jamaica southward to Brazil, South Chili, and Juan Fernandez; in Asia—Nepaul and Sikkim to Ceylon, Tsus-Sima, the Malayan Peninsula, Java,

comparatively rare species, native of New Zealand, where it is found growing on trunks of trees, are produced from a thick and closely-set crown and borne on erect stalks 3 inches to 6 inches long, of a wiry nature, and winged to the base. They are 6 inches to 18 inches long, 4 inches to 6 inches broad, three or four times divided nearly to the midrib, and of a very graceful habit, not being exactly pendulous, but arching over in a most agreeable manner through the weight of their leafy portion.

*H. SCABRUM*.—This beautiful species, native of New Zealand, is one of the most distinct, owing to the stiff hairs of a rusty brown colour with which the wiry stalks of its fronds are densely clothed.

Its handsome fronds, three times divided nearly to their midrib, are of a dark, dull green colour, which makes a very pleasing contrast with the hairs covering their stalks. Their length, inclusive of the stalks, varies from 12 inches to 18 inches, and they measure fully 5 inches in their broadest part. A somewhat airy place in the house is that which suits it best, and although it requires an abundance of water at the roots, it has the greatest aversion to being wetted overhead.

Other strong-growing kinds, such as inter-rupium, from the West Indies; Jamesoni, from the Andes of Colombia; javanicum, from Java, the Philippines, Ceylon, and Australia; Lindeni, from the Andes of Venezuela and Ecuador; myriocarpum, from Mexico and the Andes of Peru; pastoense, from the Volcano of Pasto, &c., if in commerce at all are very seldom met with in collections. S. G.

## FRUIT AND VEGETABLE CROPS.

### NORTHERN.

**Lowther Castle Gardens, Penrith.**—Apples very thin crop indeed, having suffered from severe frosts in May. Pears on walls average crop. Plums above average, especially on walls. As an orchard fruit (with the exception of Early Orleans) Plums do not finish well, but on walls are always good here. Apricots are a failure. Strawberries average crop; The Countess, James Veitch and La Grosse Sucrée especially good. Black and Red Currants above average. Raspberries full crop. Gooseberries very heavy crop, although caterpillars have been very troublesome of late. Morello and sweet Cherries average crop.—F. CLARKE.

**Alnwick.**—Apples are an exceptional crop and likely to be very fine; trees in splendid health. The dry weather does not appear to have had an injurious effect on the trees. Pears are very irregular. Apricots in some cases that I have seen here full crop. The trees have lost an extra large number of branches this year. Strawberries are grown extensively in this district, Noble and John Ruskin being grown for early use. Sir Joseph Paxton for the second early and McMahon is the very best late. The crop this season is very heavy. Raspberries are a heavy crop. Gooseberries are an enormous crop and of fine quality. Red and Black Currants are exceptionally fine. Peaches are also full crop on walls. Altogether, we have one of the finest crops of fruit that we have had for many years.

Potatoes, where not injured by frost, are turning out well. Potato crop generally is looking well. I have not heard of any disease.—GEORGE HARRIS.

**Wiggantherpe, Yorks.**—The fruit crops in this district are not heavy, but on the whole there is not much to complain of. The trees in spring were not so thickly covered with bloom as they were last year, and although we had no May frosts to destroy it, some very strong north winds did great damage, especially to trees in exposed situations, not only by destroying a quantity of bloom, but the foliage as well, shrivelling it up as though it had been burnt. May was a very dry month, and in many cases trees that carried much bloom set but little fruit. Doubtless the dry weather had something to do with this, it not being conducive to a fine set. Apples are a fair average crop, the best being Lord Suffield, Cellini, New Hawthornden, Cockpit, Manks Codlin, Keswick Collin, Stirling Castle, Lane's Prince Albert, Cox's Pomona, Tower of Glamis, and Burr Knot; the last-named is a local Apple, and one that bears every year; this season it is bearing a heavy crop, after severe thinning. It is a cooking Apple, in use during October and November, and though not one of the best, it is worth grow-

ing on account of its free bearing qualities. Pears are a very poor crop, only a few trees bearing fruit; the best are Marie Louise, Beurré Clairgeau, Winter Nelis, Passe Colmar, and Glou Morceau. Plums are up to the average, Victoria bearing best; other kinds on wall are also fruiting well. Morello Cherries are a very heavy crop, but rather small. Strawberries have also done well. Raspberries, Red Currants, and Gooseberries have been very plentiful and good. Black Currants very few. Fruit trees of all kinds have not been much infested with insect pests until late in the season, when Plums and Red Currants were attacked.

Most kinds of vegetables have done well. Some sorts of early Peas suffered from the dry weather in May; since then all crops have grown away freely. Early Potatoes are a good, crop, quite free from disease. While there has been so much complaint of the prolonged drought and its serious consequences in the south, we have been more favoured in the north. May was a very dry month, only 0.64 inch of rain falling; and although Strawberries and other small fruits, as well as vegetable crops and herbaceous plants, were beginning to suffer, heavy rains came just in time to save them. There has been no lack of moisture since then; in fact, there has been far too much rain—July being a very wet month, there having been twenty wet days, and a total fall for the month of 6.23 inches. Mildew is infesting late Peas, Onions, and other things, and I am afraid the late Potatoes and other crops will be injured if the wet weather continues. The severe winter did not do so much damage to garden crops here, there being several inches of snow during the greater part of the time, this doubtless preserving them. Great damage was done to trees and shrubs, especially the latter, a large number of the common and Portugal Laurels being killed nearly to the ground. The injury to these was not nearly so bad as at first appeared, as a large number of young conifers and other things that lost their old leaves and appeared dead, broke away again in spring.—J. S. UPEX.

### EASTERN.

**Babraham, Cambridge.**—The fruit crops here are the best we have had for some years, Apples especially being a heavy crop. Most sorts are carrying crops, noticeable being the Codlins, Prince Albert, Golden Noble, Grenadier, Flanders, Annie Elizabeth, Brabant Bellefleur, Quarrenden, Juneating, Ecklinville, Stone's, Tower of Glamis, Niton House, Hawthornden, Dumelow's, Mère de Ménage, and Cox's Orange. In most places these are all heavily laden; in fact all sorts grown hereabout where the wood was not over-strong are bearing. Pears are very thin except on walls; the cold wind must have destroyed them after they were set. Apricots suffered severely from the frost, the buds having become too forward. Plums, too, suffered in the same way, whilst those that escaped were further thinned by the cold wind. Victoria seems to have escaped well, and most trees of this sort are carrying a good crop, and Green Gages in some positions have a fair crop. The same with Damsons. Cherries are plentiful and good. Never saw trees less troubled with black fly. So far I have found insect pests less troublesome this year than any time before, probably on account of the severe weather, and so late in the season. Peaches and Nectarines are very good. Some unripened wood from last year got quite killed. Currants, Black and Red, Gooseberries, Raspberries, and Strawberries have all been good crops, but fruit, where no watering was done, was small; Nuts very plentiful.

Potatoes are still turning out well. Peas have been good; in fact, all vegetable crops are good where the cultivation has been properly attended to.—J. HILL.

**Live mere Park, Bury St. Edmunds.**—Though failures are not absent this year, I think we may say that the crop generally is over the average. The failures most felt here are those of

Apricots and sweet Cherries. In both cases the trees lost almost all their buds from the severe frost. Apples are over average, most of the trees carrying heavy crops of fine and forward fruits. Many fell during the long drought, and the Apple blossom weevil has done much damage to the foliage. The ordinary preventive means can hardly be applied to bush trees which branch almost from the ground line, and birds, which are always over-plentiful here, do not help us much. Some varieties of Apples which are generally shy bearing have good crops, and of these I may mention Blenheim Orange, Hubbard's Pearmain, Ribston Pippin, Cox's Orange Pippin, and Gloria Mundi. Pears are a good average crop, Marie Louise, Louise Bonne of Jersey, Fondante d'Automne, and Williams' Bon Chrétien being amongst the best. Peaches and Nectarines under average. Plums are over average on most trees, the weight of crop depending more on the variety than on form or position. Strawberries over average. A long struggle with the drought was overcome by one or two good waterings. Besides older favourites, such as Vicomtesse and President, Noble and Latest of All were grand. Raspberries a grand crop in every way, and lasting over a long season. Many canes were killed, but these were more than replaced by young fruiting canes of the present season's growth, which have extended the season to this time, and promise to hold out for a week or two longer. The great success of this crop is a surprise to me, and is, I think, due to heavy annual mulchings which are never removed, and to non-disturbance of the roots. Apricots a total failure, and so, too, were sweet Cherries. Morello Cherries a fair average. Red and White Currants a good average crop. Black Currants over average. Gooseberries over average. Outdoor Fig trees were killed to the ground. Outdoor Grapes almost a failure, and many canes were killed. Medlars over average. Quinces total failure. Walnuts much under average. Damsons total failure. Tomatoes are doing well, but bright weather is needed to ripen up an excellent crop.

Potatoes in deeply cultivated soil are excellent, though in the fields they suffered severely from drought, and late varieties are making a second growth, which will be fatal to good quality and shape. I have lifted the early and second early kinds. Snowdrop is again very fine, and has given scarcely any small tubers. Another kind that has turned out well is Sutton's Supreme. Windsor Castle, too, though not yet lifted, cannot have failed to do well, the haulm showing unmistakable signs of a heavy crop. Peas have done but tolerably on the light soil here, and have been much troubled with thrips. In a neighbouring garden, however, where the soil is deeper and heavier, the crops have been fine. Ne Plus Ultra is now yielding well with me. Both Onions and Celery have done grandly. The latter has been well supplied with water, and will repay for the extra labour.—J. C. TALLACK.

**Coldham Hall.**—On the whole the fruit and vegetable crops must be regarded as quite up to the average. Apples on espalier trees are plentiful and good in quality, while on large orchard trees there is an immense crop. Of Pears we have practically none. Plums and Damsons are about an average crop. Currants, Black and White, have been loaded with good fruit, but Red are not so good either in quality or quantity. Raspberries and Strawberries have borne excellent crops of fine fruit, the former being still plentiful. Gooseberries are plentiful where they escaped the caterpillars, which quite cleared a few of the older trees.

Vegetables of all kinds are abundant and good. The midseason Peas suffered a good deal from the effects of the drought, but the late kinds never looked better. Runner Beans and all root crops are looking well, but second early and late Potatoes are growing out.—H. RICHARDS.

**Hardwicke House, Bury St. Edmunds.**—The fruit crop on the whole may be considered fairly good in and around this place. Apples are heavy and the quality excellent. Pears are rather

thin, and I fear will run small. Peaches and Nectarines are very good. Apricots are almost a failure, which can be accounted for by their being such heavy crops the last two years. Cherries have been very good, also Gooseberries and Currants of all kinds. Plums are rather below the average, but the quality is good. Strawberries suffered very much from the dry weather in May and June, but those that were well watered bore heavy crops. This place did not suffer from the frost in June, but the dry weather through June and the early part of July was very trying.

Peas looked like giving out altogether, but since the rain came they have started to grow and are promising well for a good late supply.—B. MARKS.

#### MIDLAND.

**Abney Hall, Cheadle, Cheshire.**—Excepting in the early part of the summer, we had not such a dry season, and things have not suffered so much from dryness as in some of the southern counties. Apples are plentiful everywhere; Pears likewise. Cherries quite a good average. Strawberries very good. Raspberries very good. Currants and Gooseberries have also been satisfactory crops. Regarding Plums, Victorias are very heavy crops, and this is one of the best kinds to grow in this district. The Czar (a medium-sized fruit a little earlier than Victoria) is a very good one also. Plums, however, do not do so well as to merit extensive planting in this district as they do in some of the warmer southern counties. Damsons have been rather extensively planted, and now they are bearing a very heavy crop.

Potatoes are good. Peas are good. Ne Plus Ultra, which we grow for main crop, is 8 feet high and full of produce. Carrots are very good this year, which is unusual. Onions also are fairly good. Some of the Brassicæ certainly have suffered rather badly from grub and clubbing, which they generally do; but, on the whole, I think we must record a very satisfactory year with all kitchen garden crops generally—as far as I can judge at present.—ROBERT MACKELLAR.

**Knowsley, Derby.**—Apples a very heavy crop and good. Strawberries splendid crop. Red Currants heavy crop. Black Currants moderate. Gooseberries average. Cherries very good. Pears average. Peaches, Nectarines and Plums average. Owing to the very hot, dry weather in May and June, a great many of the Apples fell off, but the rain has proved very beneficial to all fruit trees, and Apples in particular, for they promise to be especially good this year and the crop very heavy. All bush fruit has kept very free from blight, with the exception of a few caterpillars on the Gooseberries. Peaches and Nectarines have a fine crop and are swelling their fruit well. I picked the first Peaches outdoors on July 22—rather early, I think, for this district.—ROBERT DOE.

**Hopton Hall, Wirksworth.**—Enormous crops of all kinds of fruit grown outside set and swelled up. When rain set in Apples thinned themselves to a small extent. Every variety grown is carrying good crops. One pyramid of the Irish Peach is a picture; this never fails. Late Apples are very fine, as they were last season. Gooseberries, Red and White Currants very fine; Black Currants moderate. Raspberries enormous crops from an old stock grown here on the same ground over sixty years. Strawberries very prolific. President taking the lead on beds twelve years old.—G. BOLAS.

**Thoresby Park, Notts.**—The past severe winter was very trying to many of our vegetables; all the Broccoli were cut off and Savoys did not escape. Brussels Sprouts suffered severely, likewise Celery, although a good covering of Bracken was on the lines. When things began to grow they did not make the progress expected from the hot days, as the nights were very cold, down to freezing, when the day temperature was exceptionally high, and the dry weather has made most things later than usual. Fruit of all sorts is plentiful and of good quality. Plums grow fairly

well, but our soil is very poor, sandy, and not at all a good Plum soil. It is not what would be considered a good fruit soil at all. Trees grow fairly well and fruit moderately well as a rule. This year we had a lot of bloom, which set well, and then one of those cold, sunless east winds came, when you could see many on the ground.—A. HENDERSON.

#### The Park Gardens, Alfreton, Derbyshire.

—I am sorry I have not replied to your letter before, but have been from home. The fruit crops in these gardens are very good this year. Apples, on the whole, are a heavy crop. Pears medium. Plums abundant (especially Victoria on standards as well as on walls). The varieties that do best with us are Victoria, Kirke's, Jefferson, and Cee's Golden Drop; these are on walls. Victoria is carrying a heavy crop on standards as well. Green Gages are heavily laden; these are on walls. Damsons a good crop. Peaches (outdoor) good. Apricots only medium owing to being overcropped two years in succession. Cherries (sweet) have here a good crop; Morelles on wall heavily cropped. Raspberries, Strawberries, Gooseberries, and all small fruit have been abundant. Garden produce generally is up to the average of a good season, independent of the long drought and the frost of June 15, which did a deal of damage to gardens in the valleys. Runner and Broad Beans suffered much on that date. The fruit crops in the neighbourhood are also good, excepting in the very low districts, which suffered from the frost very much, and the vegetable crops in the cottagers' gardens could hardly be surpassed, specially amongst those who are exhibitors at the many shows around this part.—G. M. KNIGHT.

**Barkby Hall, Leicester.**—Apples are abundant everywhere in this district. Pears are only moderate. Plums not an average crop. Apricots scarcely any. Peaches and Nectarines poor, the young wood having been killed during winter. The fruit buds of the Apricots were also killed. Gooseberries and Currants are the heaviest crops we have ever had, but they suffered during the dry weather. Raspberries heavy crop and fruit fine. Strawberries extraordinary crop, but many plants died through drought.—J. LANSDELL.

**Coddington Hall, Newark.**—The fruit crops in this neighbourhood are generally satisfactory, in spite of the severe weather experienced in January and February and the drought of early summer. Apples and Pears are very plentiful, rather under average in size, perhaps, the foliage of Pears on walls, as well as of Plums and Damsons, being much affected with spider, owing not so much to lack of root moisture as to the aid atmosphere of May and June. Louise Bonne of Jersey, Thompson's, Marie Louise, Winter Nelis, Pitmaston Duchess, Beurré Clairgeau, Jargonelle, and many other standard sorts are laden with fruit. Such Apples as Keswick Codlin, Lord Grosvenor, King of the Pippins, Duchess of Oldenburg, and Lane's Prince Albert in orchards are all laden with clean, well-shaped fruit. Espaliers are carrying good crops, especially Fearn's Pippin, Ribston Pippin, King of the Pippins, Stirling Castle, Cox's Pomona, Cellini, and Mère de Ménage, and the trees are clean and healthy. Apricots are the scarest crop I have ever known in this district; in fact, there are only a few fruits here and there. This I attribute to the severe frost coming on the immature wood and buds caused by the lack of sunshine the previous autumn. The trees, however, will doubtless benefit by the rest. Peaches on walls are a capital crop in our own garden, and the trees were never so healthy and vigorous. Hale's Early, Stirling Castle, and Dymond are my principal sorts on open walls, Amsden June doing exceedingly well as an extra early variety. Of Nectarines, Lord Napier does as well as any, nor does the fruit shrivel as it does under glass. Plums in our immediate neighbourhood are under average, although a few miles away trees are yielding good crops, especially the Victoria in market gardens. Cherries both on walls and on

standard trees have been abundant and good, Black Tartarian and Governor Wood doing best in this garden. Morelles are a heavy crop and the fruit large. Strawberries bore heavily, but the drought just at the time the fruit set, and for several weeks after, did not allow the two-year-old plants to swell off their fruit to their normal size. All points considered, Gunton Park was my best all-round Strawberry, Lord Suffield also doing well. Gooseberries and Currants of all kinds have yielded most abundantly, so much so, indeed, that the market price has ruled very low. Raspberries have been very poor, the frost having crippled the canes.—J. CRAWFORD.

**Euston Hall, Thetford.**—Of Apples we have an abundant crop, which is swelling fast and promises to be of good quality. A large standard tree of Blenheim Orange is this season bearing a heavy crop, an unusual occurrence. Pears are scarcely up to the average, and Apricots are very much under. Peaches and Nectarines are good; the trees are clean and making excellent growth. Some of our trees are trained to galvanised wire on cemented walls, others trained with nails and shreds in the usual way to the bricks; these latter are generally very clean and more free from insect attacks than the former. Of Strawberries we have had an abundance of splendid fruit, such as I never remember seeing. We mulch early, the plants never once requiring water throughout the very dry season, but I attribute the extra heavy crop to the severe thinning the bloom got in 1894; as a consequence a light crop followed, therefore the plants were in better condition to perfect the super-abundant crop this season. Raspberries did not promise well at the beginning of the season, but since the rains later fruits have been much larger, if deficient in flavour. Red, Black, and White Currants have been abundant and very fine, and Gooseberries the best crop we have had for years. Plums on walls, Kirke's, Jefferson, Magnum Bonum, and Cee's Golden Drop are fully up to the average, likewise Victoria and Orleans as pyramids and standards and Farleigh Damsons as pyramids, root pruned, are bearing satisfactorily. Morello Cherries are very fine and Filberts are plentiful.

Vegetables of all sorts are good, but as a matter of course the dry season confirmed the superiority of deeply stirred land, more especially when manure is scarce. The only crops that I notice have suffered from the effects of the severe winter are the Globe Artichokes; these were severely injured and late in throwing up their flower stalks, but are now making up for lost time and producing fine succulent heads in abundance. Sage and Lavender have been badly cut, most of the plants having been killed.—W. LOW.

## PUBLIC GARDENS.

### CHELSEA BOTANIC GARDENS.

THE old Physic Garden at Chelsea is the oldest public botanic garden in or near London, having been formed in 1673 to 1786—or about forty years after Oxford, where a garden of the kind was established in 1632. The earliest botanic gardens in England appear to have been those of Gerard and Tradescant, so that here, as in so many other branches of human progress, it was individual genius and enterprise that led to public gardens of the kind, though even our early English pioneers in pharmaceutical botany may have got some of their inspiration from the earlier botanic gardens of Italy, such as Padua (1545) and Bologna, or those of Southern Europe, such as Montpellier (1558), Leyden (1577), Leipzig (1580), Paris (Jardin du Roy), (1596-1624), and the great university at Jena (1629). The celebrated old garden at Upsala, afterwards rendered famous by Linnaeus and the Rudbecks, who issued thence their celebrated work (the "Campi Elysii"), only one perfect

copy of which is known to exist, at the Oxford Botanic Garden (Sherardian Library), though there is an imperfect copy in the Banksian books now at the British Museum. But few gardens, however, ever sprang into such sudden and well-merited importance as did that founded by the Society of Apothecaries at Chelsea in 1673, on land they had formerly acquired for their boat-house and the state barge of their company. Thus the great Evelyn writes in his well-known diary under date August 7, 1683, "I went to see Mr. Watts, keeper of the Apothecaries' Garden of Simples at Chelsea, where there is a collection of innumerable varieties of that sort particularly, besides many rare annuals, the tree bearing Jesuits' bark, which had done so much in quartian agues. What was very ingenious was the subterraneous heat, conveyed by a stove under the conservatory, all vaulted with brick, so as he has the doors and windows open in the hardest frosts, secluding only the snow."

There is a very interesting description of gardens near London that was sent to the Society of Antiquaries by the Rev. Dr. Hamilton, vice-president, and published in vol. xii. of the "Archæologia," which says: "Chelsea Physic Garden has great variety of plants both in and out of greenhouses. Their perennial green hedges and rows of different coloured herbs are very pretty, and so are the banks set with shades of herbs in the Irish stitchway."

What the shades of herbs set in the Irish stitchway may have been, I must confess I do not know, but the whole thing savours a little of bedding out, and may have been the thin end of the wedge in that direction. As I turned down Swan Walk the other day I did so with mingled feelings, for going to see an old garden is somewhat like going to see an old friend. Only one of the two old Cedars now remains, and that is on its last legs, so to speak, and it is now doubtful whether copious top-dressings and watering would do much to resuscitate its scathed old limbs and branches. The *Salisbury adiantifolia* has also suffered, one or two of its stems having been blown off during the past winter or spring. The Plane trees, Evergreen Oaks, and the *Koelreuterias* are healthy, and a fine old Mulberry was laden with its ripe and ripening harvest. The common Pomegranate is healthy here, but bore no flowers, and there is a plant of the rather uncommon *Rhus juglandifolia* near the quaint old entrance gate or "hole in the wall." It is possible that this plant is really the *R. vernicifera*, the Lacquer or Varnish Tree of Japan; at any rate I cannot find the name *Rhus "juglandifolia"* in any book on trees and shrubs I have now near me.

In one of the beds devoted to annuals I saw some nice tufts of *Eschscholtzia tenuifolia*, a dainty little Poppy-wort not often seen. Another rare plant of some economic importance has long been cultivated here, viz., *Ferula persica*, and I am glad to hear that the plant flowered during the present spring. It is a rare and handsome umbellifer, and one of the many sources of Persian *asafoetida*. The plant was formerly grown in the old College Botanic Gardens at Dublin, where it is supposed to have died after an attempt at division. All these gum-bearing umbellifers resent any interference whatever with their roots, and are best increased by seeds sown on a well-prepared spot whereon they are to grow permanently. Other plants here now seeding on strong, tall stems are *Ferula glauca*, and there is another fine species not named also seeding profusely near the large *Wistaria*.

*Malabailia Opopanax*, or *Opopanax chironium*, as it used to be called, is also seeding here,

and it was to me really a treat to see so many choice medicinal umbelliferae so luxuriant and fertile. This genus *Malabailia* is near *Peucedanum*, but has broader leaves, and the species named is figured in Sweet's "British Flower Garden," p. 283, though the figure gives but a feeble idea of the stately elegance of a well-grown specimen.

I was sorry to miss one or two old friends, and especially the spreading mass of the Gum *Tragacanth* that formerly graced the rockery stones brought from the Tower of London in 1772 by Mr. Alchorne, the honorary demonstrator, to which were added flints and chalk, given by Mr. John Chandler, and lava from a volcano in Iceland presented by Mr. Joseph Banks, for the purpose of raising an artificial rock, in order to cultivate those plants which require such a soil. This is one of the earliest records of the culture of rock-loving plants in a botanic garden known to me.

Perhaps no botanic garden can boast of effecting so much public good on such scanty means, and the galaxy of names that surround it like a golden halo is very remarkable. The whole history of the garden and those connected with it at one time or another is given in Field and Semp'e's "Memoirs of the Botanic Garden at Chelsea," published by Gilbert and Rivington, London, 1878, and from it I extract the following particulars:—

The garden having been formed in 1673, four Cedars were planted in 1683, this event forming quite an epoch in its history. One of these trees suffered from a gale in 1846, and four chairs were made of the wreckage for the use of the Hall. Piggott was the first curator, then Watts in 1680, Doody, 1706, about which time Sir Hans Sloane, the great and generous patron of the garden, and whose statue still stands in its midst, came upon the scene, Petiver in 1709, and Rand in 1724. The Sherards in 1732 both added to the credit of the place, and in 1730 the great gardener Phillip Miller became curator. He wrote his celebrated "Gardeners' Dictionary" here, the seventh edition of 1735 being his *magnum opus*, and as a lad he knew Ray, the botanist.

Linnaeus visited the garden at Chelsea in 1736, and was more civilly treated here than at Oxford, where Dillenius alluded to him as "the young man who was confounding botany." But of Chelsea, Linnaeus writes in his diary: "Miller, of Chelsea, permitted me to collect many plants in the gardens, and gave me several dried specimens collected in South America." Miller has the credit of being one of the first of English authors to embrace the then novel Linnean system of botanical arrangement, and Linnaeus' visit to England effected a revolution in the then two great gardens, viz., Chelsea and Oxford. As a curious commentary on Linnaeus' visit to Oxford, we may point out the fact that his system of arrangement as adopted soon after his visit to the Sherards has only been replaced by the natural system a few years, a fact much regretted by the antiquary and historian, however appreciable by the botanists of to-day.

Isaac Rand published his catalogue of plants grown in the garden in 1739, and then in connection with its best work come J. Miller, 1738, A. Forsyth, 1770 ("Forsythia"), Hudson ("Flora Anglica"), Alchorne, 1772, W. Curtis, originator of the *Botanical Magazine*, &c., and Sir Joseph Banks, who prided himself as having been a botanical pupil of the great Philip Miller. In 1830 Wheeler, and in 1835 Burnett, were demonstrators, and D. Don was appointed examiner, and in 1816 Wm. Anderson, the curator, died, and was buried in a grave between the bodies of Sir Hans Sloane and Philip Miller.

In 1816 Robert Fortune was curator for a short period between his voyages to China, and after him came Thos. Moore. Nat. Ward here demonstrated the value of his closed or Wardenian cases. Hoeker, M. J. Berkeley, and J. G. Baker

are other names that have added a latter-day lustre to what is even yet a most interesting and instructive garden.

The garden is about 3 acres in extent, and suffers from drought and a lack of the necessary labour and manure, but it nevertheless remains one of the focus spots of old Chelsea, and I trust that a spot so sacred to memories of the past may never fall into the hands of the speculative builder.

F. W. BURBIDGE.

## NOTES OF THE WEEK.

**A seedling Passion Flower.**—I send a bloom of a *Passiflora* raised here, a cross between *P. Constance Elliot* and, I believe, *P. caerulea maxima*. You will perceive that the rays are of the faintest shade of blue. It is almost, if not quite, hardy.—J. M., *Charmouth, Dorset*.

***Passiflora princeps*.**—I beg to enclose for your inspection three racemes of *Passiflora princeps* cut from a plant growing in a 12-inch pot. The plant has been in flower since February, and on it there are now seventy racemes as good as the enclosed.—A. G. HOOKINGS, *Olddown House, Almondsbury*.

\*\* Remarkably fine racemes of this useful and showy climber.—Ed.

***Fuchsia Riccartoni* in the Shetland Isles.**—When in the Orkney and Shetland Isles recently, the one redeeming feature of the barren, treeless country was *F. Riccartoni*, of which we saw many fine bushes, especially near Stromness in Orkney. It is a pity that no attempt at gardening, even of the simplest kind, is, as a rule, made. True, the wind sweeps over the Isles with terrific force at times, but the air is mild, and in the more sheltered places the *Fuchsia* does as well as in Southern England or Ireland.

***Victoria regia*.**—There is now to be seen in the Botanic Gardens, Regent's Park, one of the finest plants of the *Victoria regia* ever grown in this country. It covers a space of over 400 square feet, each of the eleven leaves measuring more than 7 feet across, apart from the turned up rims, which stand up 6 inches or 7 inches above the water, the deep pink of the under sides contrasting strongly with the vivid green of the upper surfaces of the leaves. The flowers, pink, and rising just over the centre of the plant, follow one another in quick succession.

***Yucca guatemalensis*.**—This (one of the finest of all the *Yuccas*) was recently flowering in the Palm house here. Its height was about 23 feet, the upper half or flowering branch proceeding from a trunk, thickened below, to which the branches are cut back after flowering. The leaves spread to a width of about 6 feet, and the plant is altogether imposing. The terminal panicle is about 3 feet in height, somewhat spindle-shaped and dense with large white flowers. It is a native of Mexico and Guatemala, having been introduced about the middle of this century.—R. I. LYNN, *Cambridge*.

**Flowers from Winchmore Hill.**—I am sending you a few flowers which I thought perhaps you would like to see, and which are very fine here at present. Among them you will find the following: Double *Polyanthus Curiosity*, *Lobelia Lord Ardilaun*, *Achillea Snowball*, *Achillea Little Gem* (this only grows 5 inches high and is very free flowering), *Aster amellus elegans*, *Haplocarpa Leichtlini*, *Centaurea ruthenica*, *Phygelius capensis*, *Haplocarpa scaposa*, *Hedysarum multijugum*, white *Lavender*, and *Anemone japonica Lord Ardilaun*.—A. PERRY.

\*\* A charming lot of well grown things.—Ed.

***Gerbera Jamesoni*.**—In spite of the last severe winter, two specimens against the wall of the stove have been extremely handsome all through the summer. The flowering season lasts about six months, but the number of flower-heads

open at one time varies from two or three in spring to about fifteen during the hottest weather. The flower-heads each measure about  $4\frac{1}{2}$  inches across and the colour has been compared to vermilion in powder. The mass of foliage is now about 2 feet high and the largest flower-scape is nearly 3 feet long. No protection is afforded in winter more than that of the glass above, which keeps off wet, but the assistance of four hot-water pipes behind the wall is no doubt considerable.—R. I. LYNCH, *Cambridge*.

**A double Begonia.**—I enclose a flower of a double Begonia, trusting it may reach you in good condition. Such a fragile flower may not stand a journey of almost 600 miles. I give measurements; circumference  $10\frac{1}{2}$  inches, depth 4 inches. I have no doubt larger flowers have been grown, but when dozens of plants can be raised from a 2s. 6d. packet of seed bearing quantities of such flowers, no one should be deterred from raising double Begonias. The soil I have found them do best in is three parts loam, one part leaf-mould and horse droppings, with a good dash of burnt refuse and fine charcoal. Large plants can be grown in 6-inch pots if the plants are occasionally given some good fertiliser.—T. SCOTT, *Ashford*.

**The Japanese Wineberry.**—My experience of this new fruit in a much colder part of the country than your Devonshire correspondent is as follows: At first I could not raise the plant from seed. An inquiry addressed to New York elicited that it was necessary for the seeds to be frozen, when they would vegetate readily. I put them out during the hard frost we had about three years ago. They were frozen hard for weeks, and on removal to the greenhouse vegetated at once. The plants were put out when large enough, and they stood the hard frost of last winter perfectly. Your correspondent exactly describes the fruit; the flavour is not unlike that of a Mulberry. I have tried it as jam and also in tarts, but in both I found that, like Raspberries, the fruit is better mixed with Red Currants; by itself it is somewhat mawkish. I find it does not like a dry soil (mine is dry), and although the plants bear well, they would evidently be much happier in a wet one. The treatment is the same as for Raspberries. The plants bear on last year's wood. I have no doubt the fruit is an acquisition, and, taken in hand and improved, will no doubt be of great value in the future.—NORTH COTSWOLD.

**Amaryllis belladonna.**—I send you here-with a flower-spike of a beautiful Amaryllis that I procured at the Cape of Good Hope some eight years ago. It seems to be similar to Amaryllis blanda, a coloured plate of which appears in Paxton's "Flower Garden." In colouring, in the shape and number of the flowers, and in height of stalk it differs from the ordinary A. belladonna, a spike of which I have enclosed for comparison. It will be seen that the bright pink veining which stains the upper half of the petal in the ordinary variety is almost entirely wanting, the only distinct colouring being a faint blush stain in the centre of the upper half of the petal. In shape the flowers more nearly approach those of the Crinums, with their trumpet-shaped blossoms, than the loose star-like open blooms of the typical A. belladonna, while the number of blooms on a scape averages fourteen, ranging from seventeen to twelve, an average, as far as my experience goes, but rarely reached by the garden variety. The flowers are also more distinctly drooping than are those of A. belladonna, and the stems sometimes reach a height of nearly 3 feet. It is undoubtedly closely allied to A. belladonna, but is, I think, more beautiful, and if but a chance variation, merits being increased. I received a few months ago over 100 bulbets from the region in which I procured my parent bulb, but shall be unable for two or three years at least to tell if any of them may be of the same strain.—S. W. F.

**The weather in West Herta.**—Another warm week, and the fifth in succession. The days were nearly all above the average in tem-

perature, while the nights, on the other hand, proved cold for the time of year. On the warmest day the highest reading in the shade was 75°, whereas on the coldest night the exposed thermometer fell to 36°. Both at 2 feet and 1 foot deep the soil temperature now stands at 61°, or, at the latter depth, about 2° above the September average. No rain worth mentioning has now fallen for nearly a fortnight; the dews on several nights, however, have been unusually heavy. The four days ending the 16th were very calm; indeed, on two of them the average rate of movement of the air at 30 feet above the ground only amounted to about a mile an hour.—E. M., *Berkhamsted*.

A. F. BARRON.

TO THE EDITOR OF THE GARDEN.

SIR,—I enclose a copy of a letter which I have sent to Sir Trevor Lawrence as the President of the R. H. S.—Yours faithfully, A. H. SMEE.

The Grange, September 11, 1895.

My dear Sir Trevor,—I should be wanting in courtesy to yourself and other members of the council if I did not give you notice of the questions which I propose to ask at the next annual meeting of Fellows, or at such early period as the council may think it desirable to call the Fellows together for the special purpose of taking them into their confidence.

I shall require the production of the minutes of the council which appointed this special committee to report upon Chiswick, the date of its appointment, the names of the committee, the reference and the scope of its inquiry, the report it made, and all the correspondence emanating from the secretary or other officer relating thereto; also a statement of the proposed changes in the management of its Chiswick Garden. I shall also ask questions which will require the production of the minute book of the garden committee, and also the minutes of all the committees (fruit and floral) which visit Chiswick for the purpose of the seed trials, &c.

The logical outcome of the action of the council—if the rumours are true—in superseding the standing committees and appointing this special committee without consulting the Chiswick Garden Committee, implies a direct vote of censure on all members of these committees, and is equivalent to a vote of non-confidence in the competency of the garden committee.

The council must see that by the appointment of this special committee questions are raised which are far more reaching in their consequences than the consideration of the dismissal of an old employé. It is a public announcement by the council to the horticultural world that they have no confidence in the ability, skill, or integrity of the forty or more members composing their committees which visit the gardens at Chiswick, and this, too, at a time when others like myself are endeavouring to raise the standard of judging at local horticultural exhibitions, and to place the judging above the suspicion of local influence. The managers of these local shows have selected their judges from members of the fruit and floral committees, whom the council by its action have considered to be unworthy of confidence for consultation as to the management of its own garden. How will it be possible for the managers of local shows to continue to employ them for judges? What, too, is the position of these members, who are employed in giving technical instruction and acting as public examiners of candidates' papers on horticulture? To my mind their character is at stake, and some action must be taken in this matter where everything depends upon confidence. The council must at a public meeting justify their action or retract their proceedings; they must either rehabilitate the character of the members of these committees or reconstruct the committees. The sooner the matter is cleared up the better, for the uncertainty which overhangs the question is doing no good to horticulture. The least that can be the

outcome of this unfortunate action of the council will be that its proceedings have been most unbusinesslike, and that they have unintentionally committed an uncourteous and stupid blunder. P.S.—I have forwarded a copy of this letter to the horticultural press.

—The official statements that have been made and the names of the special committee that advised the council in this unfortunate matter only leave matters worse. Everyone wants to know two things: the full text of the special report, and the character of the new policy which seemed to the council incompatible with the retention of Mr. Barron.—D. T. FISH.

**Drying fruit.**—There is now a great glut of Plums, Apples, and other fruit which literally do not pay the cost of gathering. It is continually asked why we do not dry them. Would some correspondent of THE GARDEN give some information how to set about it; the cost of the necessary apparatus, and where it can be got, regard being had to expense, which must not be too prohibitive for small growers?—NORTH COTSWOLD.

**The Crystal Palace fruit show.**—On Thursday, Friday, and Saturday, September 26, 27, and 28, the Royal Horticultural Society's great show of British fruit will be held at the Crystal Palace, and promises to be even a greater success than that held last year. The exhibition will be opened by the Lord Mayor, Sir Joseph Renals, at 12.30 on September 26, when he will be accompanied by the Sheriffs and the Master and Warden of the Worshipful Company of Gardeners. A public luncheon will be held the same day at 1.30 in the Grand Saloon, and will be presided over by Sir Trevor Lawrence, Bart. Lectures will be given each day of the show in the Garden Hall at 3.30 as follows: Sept. 26, "New Fruits of Recent Years," by Mr. G. Buryard; Sept. 27, "Pruning Fruit Trees," by Mr. A. H. Pearson; Sept. 28, prize essay on "The Commercial Aspect of Hardy Fruit Growing." Nurserymen and others are particularly requested to exhibit under the schedule. By direction of the council, exhibits outside the schedule will only receive cards of commendation according to merit. Vegetables other than Tomatoes are not allowed to be shown. With reference to exhibits outside the schedule, exhibitors should bear in mind the new rule adopted at the suggestion of the fruit committee, viz.: All collections of fruit are limited to 100 discs or baskets, and all dishes or baskets must be of distinct varieties of fruit, no duplicates being allowed.

**Names of plants.**—*G. H.*—Alyssum maritimum (dwarf var.).—*S. T. Spear.*—Inula pulcherrima (Fleabane).—*W. Michie.*—Yes; what is grown and used as Tarragon, but not the true Tarragon. Any nurseryman will be able to supply you with the true variety.—*G. Anderson.*—Cosmos bipinnatus albus.—*M. T. Earle.*—The scarlet-berried Elder.—*L. Woodhouse.*—1, Clematis Jackmanni alba; 2, Clematis flammula.—*Nurserymen.*—Conifers: 1, Biota orientalis Zuccariniana; 2, Thuja occidentalis Dicksoni; 3, Retinospora obtusa var.; 4, Biota orientalis filiformis; 5, Biota orientalis var.; 6, Picea nigra Donnetii; 7, Juniperus virginiana; 8, Thuja plicata; 9, Picea pungens glauca; 10, Pinus Balfouriana; 11, Biota orientalis var.—*Isaac Turner.*—Probably Celastrus sp. and hardy.—*Anon.*—Ficoides orientalis.—*Z. Z.*—1, Polygonum cuspidatum; 2, Catalpa bignonioides; 3, Aristolochia Siph.—*S. H. G.*—1, next week; 2, common Polypody; 3, Nepenthes molle; 4, Asplenium viviparum; 5, Nepeta Musini; 6, Agathaea culestis; 7, Fuchsia Mrs. Marshall; 8, Sedum sp.; 9, Rose Gloire de Rosomanes.—*Geo. Anderson.*—Cosmos bipinnatus albus.—*Hon. A. T.*—Eupatorium cannabinum (the Hemp Agrimony).

**Names of fruit.**—*J. R. N.*—Pear Fondante d'Automne.—*Miss George.*—Pears: 1, Williams' Bon Chrétien; 2, Emilie d'Heyst. Apples: 1, Mère de Ménéage; 2, Hawth ruden; 3, Cox's Orange; 4, Ribston; 5, not recognised; 6, Lord Derby.—*J. D.*—Pear Deux Sœurs. Apples: 1, York-hire Beauty; 2, King of the Pippins; 3, Golden Noble; 4, Lord Suffield.—*Scaton F. Taylor.*—Apples: 20, New Hawthornden; 15 and 25, Lord Suffield; 23, Dutch Mignonne; Pears: 28, Beurré Bosc; 19, Beurré Diel.

No. 1245. SATURDAY, September 28, 1895. Vol. XLVIII.

"This is an Art  
Which does mend Nature: change it rather; but  
THE ART ITSELF IS NATURE."—Shakespeare.

## ORCHARD AND FRUIT GARDEN.

### COMMON SWEETWATER GRAPE.

SINCE it has been possible to build vineries so cheaply, Grape culture against open walls has been largely discontinued; but the experience of 1893 and 1895 ought to have the effect of once more bringing into prominence the desirability of clothing sunny house fronts with Grape Vines. It is true many old Vines were badly crippled by the frosts of last winter, but in several instances summer neglect was largely responsible for the winter failure. When the lateral growth is allowed to grow at will, completely smothering the few bunches that show and the main rods generally, pruning—in this case another name for rough trimming—being deferred till late in the season, it is not to be expected that the Vines will be either perfectly hardy or productive. If the same pains were taken with outdoor Vines as are bestowed on those under glass, there would be fewer failures. I hold that the Grape Vine is most suitable for clothing sunny house fronts, more especially in the south of England, and certainly far preferable to either naked walls, badly mildewed Roses, rambling Roses that give but little flower and end up in breaking down wholesale, common Ivy and overgrown Virginian Creepers. During the summer a well-kept Vine proves distinctly ornamental, and in many instances would yield a heavy crop of very acceptable Grapes. The main rods ought to be trained about 3 feet apart, as it is a decided mistake to crowd them in any way. It is also unwise to attempt the growth of extra long rods in one season, as these fail to ripen properly; whereas a length of 6 feet to 8 feet, duly stopped and lateral growth pinched back to the first joint, becomes moderately stout and strong, and ripens sufficiently well to both withstand frosts and produce bunches freely.

As far as my experience goes, it is the common Sweetwater that is the most reliable variety both as regards productiveness and ripening. It is also the least addicted to mildew. As a boy I well remember seeing grand crops of this Grape grown on south fronts of dwelling houses and high garden walls, and in those days tenpence per pound was the price obtained for them without very much difficulty. It is not the fault of our climate that we meet with so few examples of successful culture now-a-days, but rather, as before hinted, the faulty treatment given the Vines. Forty years ago Black Hamburgh would occasionally produce heavy crops of bunches, but the berries, though black, were never remarkable for their good quality any more than they were in 1893 or are likely to be this season. Then, as now, mildew was the cause of many failures with the Black Hamburgh, and it never was suited to open-air culture. Black Cluster or Black Burgundy is a sure cropper, but the bunches are small, dense, and the quality second rate. Early Ascot Frontignan and Early Summer Frontignan are also recommended for open-air culture, but of these I cannot speak from experience, and till I meet with something better shall go on recommending the common Sweetwater or Royal Muscadine, as more properly named.

Not only is this the best in my estimation for open-air culture, but it also deserves a place in the amateur's vineery. No other variety succeeds so well against a back wall, and it is there where it should be grown. For the first two or three years the crops will be heavy and the bunches large, and in later years there will still be plenty of bunches, only, always provided sunshine is not wholly shut out from the Vines, they will be smaller. A narrow space between the laterals of the Vines on the roof will admit sufficient sunshine to those on the walls to ensure ripening of both wood and crops. So well does the common Sweetwater succeed under this treatment, that I have seen better crops of bunches ripening against vineery back walls than are had from the roof, the varieties in the latter case being Black Hamburgh and Foster's Seedling. It cannot be claimed for the common Sweetwater that it is richly flavoured, and as a matter of fact it is this very absence of richness that pleases invalids. It is a very refreshing Grape, and grown under glass is also fairly attractive in appearance, especially when lightly thinned.

W. IGGULDEN.

**A capricious Vine.**—A peculiar freak has occurred on one of the Muscat Vines here. Three years ago a young rod was taken up on each side of one of the Vines (Muscat of Alexandria), and these have carried fruit for the first time this year. On the main rod and on one of the young rods the Grapes set well and are of the normal size and shape, but on the other young rod the bunches set badly, and only one really presentable bunch has been produced, this quite low down on the rod. The berries on this bunch and the few others which set on the other apologies for bunches are very large and round, having, in fact, all the characteristics of Cannon Hall Muscat, the stronger growth, form of leaf and general habit of growth aiding the deception. Had I not been certain to the contrary, I should have concluded that the Muscat of Alexandria had been worked on the Cannon Hall stock, but all the Vines in this house I planted myself and cut down to within a foot of the soil at the first pruning, while the point from which the young rod springs is about 6 feet from the border.—J. C. TALLACK, *Livermere Park*.

**Canker in fruit trees.**—It may interest those who are troubled with this disease in Apple trees to know the result of an experiment made last winter at Gunton with a view to its extermination. A row each of Lord Suffield and Potts' Seedling Apples in bush form were affected with this malady, so much so, indeed, that there was scarcely a clean branch visible in any one of the trees. Soluble paraffin was mixed with dry powdered clay and made of the consistency of paint, being afterwards well rubbed into the affected parts with a rough painter's brush. The result was that all the diseased portion healed up, and at the present time the trees present a very healthy appearance. No doubt canker is often encouraged by the roots being in an unsuitable medium, but some varieties are prone to canker in any soils and when well treated, hence the value of the above remedy.—J. C.

**Early dessert Apples.**—Apples are plentiful this season and, I notice in many places, smaller than usual on account of the heavy crop, and, of course, less valuable. Our best early dessert Apples this season are the older kinds, such as Irish Peach, Yellow Ingestre, and Devonshire Quarrenden, a good trio, but if I were obliged to select only one, I should give the preference to Quarrenden, as this may be had good much longer than the Irish Peach. The last-named (when stored early) soon shrivels, and is then almost valueless. The same remarks apply to most of the other very early kinds, as they are best gathered and eaten direct from the trees. Worcester Pearmain may be a good market fruit, but in my opinion, as regards flavour, it is only second rate, and should not be largely planted

for home consumption. Mr. Gladstone, another very early fruit, has borne well this season, and is most valuable on account of its earliness, and if it had a brisker flavour it would be more appreciated: the flavour is better when the trees are grown in standard form. Duchess of Gloucester or Duchess' Favourite is not grown so much as it deserves. The fruit is of a glowing red and firmer texture than Worcester Pearmain and keeps longer. It is a prolific kind and does well grown as a standard. The newer Lady Sudeley, doubtless one of the handsomest early dessert Apples grown, cannot be termed of first-rate quality, it soon getting soft and flavourless when stored. Red Astrachan, a highly coloured fruit and very early, soon loses flavour when gathered. It cannot be termed profitable if grown in quantity in a private garden. Most of these early fruits lack good flavour, so need not be largely grown. Such old varieties as Irish Peach, Kerry Pippin, and Devonshire Quarrenden are difficult to beat when flavour is considered.—W. S.

**Pear Glou Morceau.**—This Pear is not always reliable, but this season any trees that I have seen are bearing freely; indeed, many are above the average. The same good qualities were noticed in 1893 when we had a hot, dry summer. Heat appears to suit this variety, as every kind of tree, whether on a wall, as a bush or a pyramid, is fruiting. The fruits this season are not so irregular in shape and the skin is much clearer. This is known as a December Pear, but from appearance I do not think the fruit will keep into December; indeed, many of the mid-season and later kinds will be much earlier, and I fear we shall not have many good Pears left for the new year.—G. WYTHES.

**Peach Barrington on a west wall.**—I have never seen any variety crop better than this on a west wall. The fruits are very fine, the colour all one could desire and the flavour splendid. This variety is not subject to mildew and the trees rarely fail to fruit. I am aware it is not considered by some equal in flavour to Noblesse, but I fail to see any objection on that score. Being somewhat late, the fruit is valuable on that account, as it ripens at a season when Peaches are none too plentiful. Two seasons ago, seeing how well this variety did in a poor soil, I planted it largely, and it has given fine crops. It deserves room in all gardens where late Peaches are required.—S. H.

### OUTDOOR FIGS.

SEVERAL correspondents have recently been writing of outdoor Figs, and I have been appealed to to say how it fared with them last February and since. The answer is not very encouraging. It must be admitted that the severe frosts inflicted serious injury on many outdoor Figs in East Anglia and elsewhere. From what I have seen and heard there is comparatively little difference between the protected and unprotected Fig trees. This seems rather paradoxical at first sight, but on reflection and inquiry, the injury to protected Figs to the same or a lower level than to the unprotected is only what might be expected, for the following reasons: First, open-air Figs are seldom sufficiently protected to shut out anything like 30° or more of frost. Secondly, were such excessive protection given, it would so greatly weaken the trees that a less degree of frost would do them far more injury than a greater amount of cold would do the harder unprotected trees. And finally, the greatest injuries inflicted on open-air Figs do not arise from actual freezing in winter, but through chills and changes of temperature in the spring. It was through a careful study for years of these facts on walls and build-protection to outdoor Figs, and I have had some ings that I determined to abolish any and all fine crops on roofs as well as walls and buildings without any protection whatever. Mr. Crawford asks about the East Anglian Figs this summer. Those trees and portions of trees that escaped the killing frosts have ripened, or are ripening

some good crops, but numbers of trees have been cruelly mangled, and coddled and pampered trees have been cut down to the ground. I saw a fine wall in a large garden last week every tree on which had to start afresh from the base. I cannot help thinking that not only is protection to outdoor Figs a mistake, but that the summer pruning advocated by Mr. Crawford and "W. G. C.," and no doubt practiced by many others, is a more serious mistake still, for what do such operations effect for the Fig? Thinning the shoots or wood is said to ripen it. But does it? I boldly say, no. Whatever may be true of the wood of other fruit trees, the thinning of Fig shoots concentrates the vital force meant for the whole into fewer or less shoots. By thus concentrating growing force the strength of the shoots is increased. The stronger the Fig shoots the longer they will and do grow and the later will the wood be in ripening; therefore, the thinning of Fig shoots, so far as it concentrates strength, hinders and cannot foster early and thorough maturity of wood.

The single, double or multiple stopping of Fig shoots in the open air is still more mischievous and antagonistic to the perfect maturity of Fig wood. Through hard treatment at the root and full exposure of the tops we may so crib, cabin and confine growth as to force maturity of fruit and wood within the narrow compass of a season's growth in the open air. But attempt to ripen two or more growths of the Fig in the open air and failure is inevitable. The climate and the semi-tropical character of the Fig forbid the accomplishment of such impossibilities. Under glass with temperature under complete control your correspondents may thin and stop their Fig shoots as they list and gather Figs almost all the year round if so disposed. But there is, so far as I have discovered, only one tolerably sure and certain mode to an annual crop of good Figs out of doors, and that is through a starving *régimen* at the roots and leaving the tops severely alone, only helping them up and over larger, higher, and yet wider areas. Many of the finest trees I have seen throughout East Anglia have been thus roughly treated and they have yielded bushels of Figs for years. Notwithstanding the many additions of late years to our varieties of Figs, I know of none to compare with the old Brunswick and the Brown Turkey for thus roughing it over gable ends, garden walls, or over the roofs of stables, cow sheds and other buildings. In my first situation in East Anglia I was compelled to grow Figs in the open air. I planted in ordinary borders and grew fishing rods. I lifted the rods, cleared out their root-runs, rammed in instead a yard deep of lime rubbish, brickbats, road sand and loam, in which I planted the Figs and they fruited for years. D. T. F.

**Early decay of fruit.**—Have growers who have many varieties of Apples and Pears noticed that this season the nearly ripe fruits of various Pears, especially the large kinds, are decaying badly on the trees and dropping prematurely, many of the fruits being lost? The worst Pears are Pitmaston Duchess, Marie Louise, Bourné Bachelier, and other varieties with a soft skin. Large Apples, such as the Codlins and early varieties, have been bad in this respect, many of the large fruits decaying before the skin changes colour. If this decay is likely to continue when the fruits are stored, I fear there will be heavy losses, as it is the largest fruits which suffer. I am inclined to think the weather of late answerable, as upon close examination the fruits are not injured by birds, but decay commences at the stalk. This may be owing to the fruits being over-charged with moisture, as the trees suffered from drought early in the summer, whereas now there have been heavy rains. W. S.

**Plum Bollo de Septiembre.**—This is, I consider, one of the very best late Plums grown. I am aware it is not the latest, as there are several others, such as Wydale, which hangs till November, and Monarch, a very fine late variety. Bollo

de Septiembre is distinct from those named, being sweeter and a very fine fruit for tarts and preserving when the season is nearly over. It is not always a sure cropper in rich soils, growing very strongly, but I get good crops from standard trees by root-pruning and thinning out useless wood. My trees on a north border never fail to fruit freely. The fruits are large, roundish, skin reddish purple, with a nice bloom, flesh yellow, juicy, sweet, and refreshing. The fruit will hang well into October, and those who may not require to grow it in standard form will find it a profitable variety, given bush culture, if the knife is not used too severely and there is room for the trees to grow freely.—G. W. S.

**Apples in East Anglia.**—The Apple crop generally on ordinary orchard trees in Norfolk is a very poor one, owing to the desolating wind which swept over the county about the middle of May just when the trees were in full flower. Some of the earlier varieties were sufficiently advanced to stand the shock and are bearing fair crops. In several gardens which I visited there is abundance of average-sized fruit on espalier and bush trees, these being lower and more sheltered than the standards. The disastrous effects of these gales ought to teach us the need for ample shelter, a point which even now-a-days is frequently overlooked in the formation of new orchards. As a further proof that the failure of the crop was due to the cutting wind, I may mention that in some instances a partial crop of fruit may be found on the side of the tree opposite to that from which the storm raged.—J. C.

#### INFLUENCE OF SEASONS ON FRUIT.

It will be remembered that during the hot summer of 1893 both Pears and Apples grew to an enormous size. In this district many fruits of the former of such varieties as Glou Morceau, Beurré Diel, Van Mons Leon Leclerc, Gansel's Bergamot, and others weighed considerably over a pound each, while some of the larger kinds of Apples, like Warner's King, Peasgood's Nonsuch, Ecklinville, and Loddington were over 20 czs. Now the rainfall in this part of the country between March 1 and June 22 in 1893 was only a little over an inch, while during the same period of the present year it exceeded 4½ inches. In 1893, between June 22 and September 1, there was a trifle over 5½ inches of rainfall, and between these latter dates of the present year there has been a fall of 6½ inches. By this it will be seen we have had about 4½ inches more of rain between March 1 and September 1 this year than we had in 1893, yet with us the fruit is not nearly so large this season as it was then. How is this great difference to be accounted for? As will be seen from the above, there has during the last three months of the present year been about three-quarters of an inch more rainfall than there was during the same period two years ago. In June, 1893, there was 1.36 inches of rain, while in the same month of the present year there was only .36 inch. In July of both seasons the difference is so slight as to scarcely be worth notice, there being just a trifle over 3.50 inches in both instances. In August, however, of the two years we find a great difference, for during that month in 1893 there was only .73 of an inch, while in the present year there have fallen 2.42 inches. It would appear from this that the rain which fell in June, 1893, was far more beneficial to the fruit crop than that of August, as it kept the sap flowing freely, inducing the fruit to swell, and instead of remaining for some time at a standstill, as was the case this season, it grew away rapidly from the first. From this we may learn a lesson with regard to watering, as it will be seen by the above that in order to have the largest

fruit the trees must be attended to while the fruit is small and the wood sappy, for if neglected at such a time it will be difficult to make up for the loss afterwards, even though the trees are mulched and fed. We have of late experienced some very bright sunshine, such in fact as is seldom known in this country so late in the season. With us an ordinary thermometer suspended to a post in the centre of the garden for three days in succession registered 111°, 103°, and 109°, while in the shade the temperature on the same days was 86°, 81°, and 82°. The bright sunshine has had a serious effect on many kinds of early Apples that were fully exposed and approaching maturity. Some varieties, such as The Queen, Peasgood's Nonsuch, Cox's Pomona, Warner's King, Pott's Seedling, Loddington, and others of a like nature, were so scalded by the action of the sun as to turn brown and become quite soft before evening. I have never seen anything like this before, and shall be curious to know if anyone else has experienced the same thing. Our soil is a poor, stiff loam resting on rock, and though very retentive, it does not seem to have held sufficient moisture to supply the fruit during such weather, though the trees do not seem to have been affected in the least, as the foliage is quite green and healthy. Pears have not grown so well with us as they did in 1893, though some kinds, like Huyshe's Victoria, Fondante d'Automne, Passe Colmar, and Winter Nelis, are far better this year than they were two seasons ago. It seems a great pity that most of our best Pears are fast going out of cultivation, and this on account of large worthless varieties taking their place. It is a pity that such delicious kinds as Seckle, Comte de Lamy, Ne Plus Meuris, Winter Nelis, Jean de Witte, Zephirin Gregoire, Thompson's, Dana's Hovey, Beurré Superfin, Doynenné Defays, Aston Town, and others that do not find favour with judges on the exhibition table do not receive more attention. If Pears are only to be grown for exhibition, then the sooner fruit shows are put an end to, the better will it be both for the gardener and his employer. I wonder how many fruit judges of the present day know what a good Pear really is, or the value of first-class flavoured sorts. Until competent judges are engaged at our large shows or some standard is given for them to work upon the same thing will go on, prizes being awarded for varieties with no better flavour than Turnips, while those which are really first-class are passed over. It is quite time that gardeners protested against this kind of thing and have fruit judged on its merits, otherwise it is useless to grow fruit of good quality.

H. C. PRINSEP.

**Slugworm on Pear trees.**—This pest is more troublesome in many parts of the country this season than usual. I have seen many fine healthy Pear trees almost divested of foliage by its ravages. The great difficulty is reaching them when in the minute caterpillar state, as these are located between the leaves, the latter being quite sealed together by the web. One old fruit grower much troubled with this pest recently told me that when the slug state is reached he soon clears his trees of it by an application of lime and fine sand. The former must be fresh slaked and the two mixed in the proportion of one of lime to two of sand, and dusted freely over the trees at eventide.—J. C.

**Red spider on Vines.**—This insidious pest is doubtless the greatest curse the grape grower has to deal with, and, unless duly checked, terribly speedy in its work of destruction. During the past few summers gardeners who formerly were able to keep it under by fumes arising from

sulphur-coated hot-water pipes have been beaten in their attempts, so persistent have been its attacks, especially in exposed situations and on light well-drained soils. Several noted growers and exhibitors have now taken to what was at one time considered a barbarous practice, viz., peeling off the greater portion of the bark and afterwards well dressing the rods with some insecticide, believing that applying the dressing over the old rough bark was useless, the insects being secreted underneath and out of its reach. Since practising this their Vines have suffered very little from red spider. Mr. Allan, of Gunton, now adopts this plan, using soluble paraffin and clay. The latter is first dried, then powdered and moistened with pure soft water, being afterwards rendered of the consistency of paint by the addition of the paraffin; by this means an overdose of paraffin is avoided. This applied with a painter's brush after peeling keeps the Vines clean throughout the season. Mr. Allan does not think the rough bark so necessary as a protection against sun heat as some people imagine, the foliage of healthy Vines duly protecting the rods. The healthy condition of the Vines at Gunton convinces me of the soundness of the remedy, especially after a dry season like the present, and I intend trying it myself next winter.—J. CRAWFORD.

**Apple Nanny.**—How seldom this Apple is met with in private gardens, yet it is really a first-rate variety, coming into use at the end of September when dessert varieties are scarce. About Havant, and just within the borders of Sussex, this Apple is largely grown. It is a tremendous cropper, the fruit of medium size, greenish yellow, with broken streaks of red on the shaded side, and of a brighter red on the sunny side, streaked with dark crimson. When in condition it is of excellent flavour, but does not long remain so.—E. M.

FRUIT NOTES FROM BUSHILL PARK NURSERIES.

GARDENERS who may happen to be in the neighbourhood of Enfield should, if possible, visit the above nurseries. Pot Vines are grown by the thousand, and Messrs. Low appear to be alive to the fact that planters now-a-days refuse to purchase Vines that have been plunged in bottom-heat. At Bushill the pots are stood on a hard bottom of ashes on each side of long span-roofed houses, ample room being left for the ingress of light and air. A splendid lot of Muscats, as well as ordinary varieties, with strong short jointed canes may be seen, the pots being filled with hard wiry roots that will stand exposure in autumn and winter far better than those grown in hotbeds of tan or leaves. I noticed a batch of canes in 6-inch pots intended for cutting back and growing into fruiting rods next summer. I learnt that some growers prefer these to larger ones for planting in permanent borders. A special feature of this nursery is the Peach and Nectarine trees grown and fruited in pots under glass, this being done in order that planters may have an opportunity of seeing and even tasting the various varieties. Old standard sorts of Peaches, such as Royal George, Stirling Castle, Gros Mignonne, and Belle-garde were represented by healthy specimens carrying fine crops of good-sized highly-coloured fruit. Old Elruge, Stanswick Elruge, Rivers' Orange, Humboldt, about the best of the yellow fleshed section, and Lord Napier were most conspicuous amongst Nectarines, the bright perfectly-finished fruit of the last strengthening my opinion that this fine-flavoured Nectarine is less liable to sunstroke and shrivelling grown in pots and partially shaded by the foliage than on trees trained close to the glass. Chaucer, a variety I never heard of before, appears to be a splendid Nectarine; in fact, so far as size and colour go, I have never seen its equal. The stock of trained Peaches, Nectarines, and Apricots in the open ground is a sight worth seeing. Many hundreds of absolutely faultless trees might be picked out, and in proof that the knife has been judiciously

used, I may mention that the lower branches are as strong, and in some instances even stronger, than the more upright and central ones, which is unfortunately seldom the case in nursery trained trees. The wood of these, although strong, is wonderfully short-jointed, and such as with a fair autumn will ripen well before the lifting time arrives. The same faultless condition is observable in the extensive breadths of Apples, Pears, and Plums; no overgrown specimens are visible, the annual demand being so great that a clearance is always effected. Space will not permit of speaking in detail of the many thousands of forcing subjects grown in pots and of the almost unparalleled quantities of Roses, all in perfect health.

J. C.

NOTES ON APRICOTS.

Mr. Crook (p. 193) gives us some interesting notes about the growing of Apricots. Whether trees require so much water generally is open to question, as one cannot lay down a universal rule guiding this detail of culture. The whole question of supplying the trees with water hinges of course upon the soil of each locality. While a light sandy soil would not grow this fruit at all without the aid of water in abundance, that which is just the opposite in character would require treating otherwise. The late Mr. Wildsmith grew Apricots in quantity at Heckfield, and in doing so he relied much upon a free water supply, not only during the time the fruit was upon the trees, but after it was gathered he used to thoroughly soak the soil next to the wall several times. Now at Wilton Park Mr. Challis grows equally good Apricots upon trees facing the south; he does not depend so much upon the moisture artificially supplied, but rather the reverse. The roots are mainly confined to a border 3 feet wide, the remainder in front being cropped with small-growing vegetables and salads. By trenching the part devoted to vegetables every year, the annual root-pruning the trees receive induces them to make a mass of fibrous roots, which are a great benefit to the trees. Mr. Challis believes in having the surface quite loose to guard against evaporation of moisture from the soil. To assure this, he occasionally forks over the surface 2 inches or 3 inches deep, and adds to it occasionally a top-dressing of burnt earth and old lime rubble. This not only acts as a mulch, but provides the roots with the necessary nutriment required by stone fruit. Natural circumstances as to soil and situation must be taken into consideration before adopting any hard and fast rule. I know an Apricot tree which is over two hundred years old. Within about 60 feet of the tree is a large pond, and no doubt the roots of the Apricot are at the edge of the pond, thus deriving considerable aid from the moisture obtained there.

E. M.

**Melon Golden Perfection.**—I also have a good word to say for this Melon. I have grown it for the last twenty years until the last two seasons, when it got crowded out by so many newer sorts that one was anxious to give a trial to. Golden Perfection is a splendid Melon in every respect as regards freedom in setting and swelling its fruit to a good size and flavour. Rather a longer period is required to ripen its fruit than with many other sorts, which is a point in its favour rather than the reverse, because where several varieties are grown in one house or frame a longer continuance of ripe fruit is the result.—E. M.

**Apple Cox's Orange Pippin.**—I am surprised to hear that this Apple does not succeed at Claremont. It grows wonderfully well here, bearing very heavily most years. One tree—a rather low-grown standard—is really a sight at the present time. This Apple requires very little pruning indeed beyond thinning the shoots to enable the wood to get ripened. Shoots of the current season's growth 18 inches or more long will produce fruit in 1897 in the usual course of events. There are far too much pruning and

spurring in of the young wood of many sorts of Apple trees to obtain the best results.—E. M.

**Apple Keswick Codlin.**—What a pity this Apple is not more favourably looked upon by market men. In some towns they will not have it at any price. The objection to the old Keswick is, that the fruit being so soft, it will not bear handling as often as is required in a retail trade. No Apple has a better appearance on the tree when it is thoroughly ripe, and as to its cropping qualities, they cannot be excelled; no housewife would wish for a better Apple for cooking, I am sure. For private gardens I always advise that a tree or two of this Apple be planted to come in as second early. It should not be closely pruned. Treated more on the extension system it fruits abundantly, and the branches should be well thinned out.—E. M.

KITCHEN GARDEN.

BEET AND CARROT CROPS.

Good breadths of Beet are few and far between. Much of the seed sown failed to germinate till the rains came, or if it did, the plants only existed, as it is very certain very little was seen of them much before August. Where the hoe was not run through the beds and a fresh start made the crops in most instances are very irregular. A portion of the plants or those that came up early and kept growing have developed into monstrosities, or something between a Beet and a Mangold, while the rest are too small to be of much value for cooking. Some growers blame the seedsmen, or rather the strains of seed supplied them, for this breakdown, and if there were only a few isolated instances they might have good grounds for blaming them. As it happens, the same state of affairs prevails in large and small private gardens, in market gardens, cottage gardens, and allotments, and all could not have been supplied with much mixed or badly saved seed. I think we must credit the season of 1895 with the extraordinary behaviour of Beet. The tropical heat of the early part of the summer, followed by soaking rains and then more strong heat, simply made the Beet grow out of all character. Turnip-rooted forms were the first to show signs of becoming far too coarse, and at the present time very few indeed of these roots are fit for use. Those transplanted, however, did not behave quite so badly, and some of these are now no larger than tennis balls. In the Dell's Crimson type we have one noteworthy exception to the rule as far as coarseness is concerned, but, unfortunately, want of robustness in this instance proved somewhat of a drawback, and I have seen beds of it in which a fortnight ago there was scarcely a root large enough for cooking. This class of Beet always pays for rather high culture, that is to say, should have ground only partially exhausted of manure applied for preceding crop, or else a dressing of manure should be dug in deeply by way of preventive of forked roots. Soils not naturally free working ought always to be dug, and in some cases re-dug, long enough in advance of sowing to admit of these breaking down finely, and moderately early sowing, timely thinning out, and a free use of the hoe between the rows ought to do the rest. Beet is an important crop, and should not be relegated to any breadth of ground that happens to be vacant at the time seed must be sown. With only extra large and very small roots to depend upon the question is, what can be done to meet the inevitable demand for Beet? Personally I shall not be in a hurry to hand the coarse roots over to cows or pigs. Some of them are of a

better colour throughout than might be expected, and the attempt should be made to properly cook these, say, after the smaller roots, and which will soon become still smaller unless left in the ground and protected, are used up. If cooked for about four hours they ought to be well softened throughout, and if the colour and flavour are good, they might be cut transversely and then stamped into circles or diamond-shaped pieces. The small roots, if lifted, should be packed in moist sand, but would keep better and probably improve in size if left where they are, protecting from severe frosts directly these are imminent. They may be banked heavily with either ashes, fine soil or leaves.

#### CARROTS.

are sufficiently plentiful and coarse enough to please all who place weight before quality. Strains have been improved in the wrong direction. What a few years ago would have been considered perfect would now be thought too small—at any rate, from an exhibitor's point of view—and a cross between an Intermediate and Long Surrey, that is to say, an overgrown Intermediate, is the result. Saw these large-growing varieties early in April and the chances are there will be found when lifting a great percentage of cracked or split roots and the rest be too large for cooking whole. Every cook and every gardener ought to be well aware that if a Carrot is sliced up prior to being boiled the flavour is spoilt. Too often these mutilated roots are only half cooked, so that they come to the table both hard and tasteless. A Carrot should be boiled whole, and long enough to become quite soft throughout, quartering it if need be after cooking has taken place. If one hour's gentle boiling is not enough, then extend the time another half hour or longer. More often than not half an hour is the time allowed for cooking or rather spoiling Carrots. Gardeners are quite as much to blame as cooks. Instead of having great coarse roots for the table they ought to send in small and comparatively young roots, the larger ones answering well enough for flavouring. Either sow later and thin lightly, or else depend largely upon the stump-rooted forms, Nantes Horn being one of the best for the purpose. It is astonishing what a number of small roots suitable for cooking whole can be had from a row or rows of any variety of Carrot either very lightly thinned or not thinned at all. This has been the experience in many gardens, but in how many instances has it been profited by? There should be several rows only very lightly thinned, the most serviceable roots being those that actually press against each other. Sowing in June and July is also desirable as a means of keeping up a supply of tender young roots. None of these undersized roots should be drawn and stored, unless in anticipation of an extra severe frost, this rendering the ground too hard for drawing, as they keep better, are sweeter and more tender when drawn direct from the open ground. Mulch with straw litter. W. JACOBSEN.

**Large Onions.**—I note most of the prizes at the late show at Chiswick were awarded to huge bulbs with modern names, the older kinds not having the least chance, though I know well which would be the best in five or six months' time, a season when Onions are valuable. I am not finding fault with what may be termed well-grown bulbs, as these are good for serving whole, but with the large Onions which take more than a season to grow. I do think in judging the quality of any vegetable mere size should not be considered. We do not want Onions over 1 lb. in weight or that take nearly twelve months to grow. For show they make their mark, but for use they

are nowhere. I also noticed some of the bulbs looked as if they had been grown in more favourable climates. Although glass is now at most large growers' command, I do think it can be made more useful than for the production of these giant roots that will not keep, and which are certainly not profitable. Judges at shows would not award prizes to many vegetables which only had coarseness to recommend them, and why should this increased size in Onions be encouraged? Why not make a stand at a certain size and encourage good culture, but not that which does not add to quality? I regret to say we are losing sight of one of the chief points—quality, as it will be found after a certain size is obtained there are deterioration and loss. I was in hopes that at Chiswick this point, namely, size before quality, would be considered. This was a simple matter in the single dish class, but more difficult with collections, as, placing the Onions on one side, there was fine quality in a large number of the exhibits. In most of the collections I was glad to see that mere size was a secondary consideration.—CRITIC.

**Pea Holloway Rival.**—Though not one of the new kinds of garden Peas, this should not be overlooked by those who appreciate a sweet-flavoured, large-sized Pea, for I doubt if there are many to excel it in these points together with the vigorous habit and dwarf growth in the haulm. It is good as a midseason kind, but is even better, I believe, as a late sort, and for late gathering, I purpose growing it more largely another season. In a raw state it has been the sweetest Pea I have tasted this year, and though not one of the large exhibition kinds, its yield is better than many of them, the Peas being extra large and the pods filled to the extreme end.—W. S.

**Tomatoes at Warley Place.**—One of the grandest crops of Tomatoes I have seen for many years is growing on a west wall in the new kitchen garden at Warley Place, Essex. The variety is Reading Perfection, and many of the finest fruit would each, I am sure, weigh close on a pound. It was not, however, the size of the individual fruit that struck me so much as the heavy and even crop. Quantities have already been gathered, and there still remain innumerable clusters both in a ripening and semi-green condition. The soil is quite newly turned up, and although not over-rich, apparently just suits the Tomato. The plants were raised early and planted out in good time, which cannot always be done in gardens lacking shelter, which is one of the points in favour of the new kitchen garden at Warley Place.—J. C.

**Cabbage Sutton's Little Gem.**—I have this season grown the above for the first time and am much pleased with it. It may be termed a summer Ellam's, which is, I consider, the best early spring variety, Little Gem being invaluable for summer cutting. For the supply from July to September it is excellent, and without the strong flavour summer Cabbages usually possess. Little Gem is well named, it being a small variety with very compact habit, having few outer leaves. The hearts are inclined to be cone-shaped, and remain good for some time. If sown in April and again in June there will be a long supply of delicate little Cabbages at a season this vegetable is not always good. I have not tried this for early spring cutting. For market it may be considered too small, but for private gardens it is a great gain, as it can be grown in a limited space and soon turns in.—G. WYTHES.

**Good winter Cabbages.**—The Coleworts are mostly grown for early winter supplies, but they are most valuable at the end of the year. From January to March there is room for good Cabbages (varieties that will stand a certain amount of severe weather and which do not split). So far with me none have proved better than St. John's Day and Christmas Drumhead. The former is a choice Cabbage and of the most delicate flavour possible. The plant is of compact growth, taking up little space. The hearts have a flattened or Drumhead shape, but the variety is quite distinct from the ordinary Drumhead type, being smaller,

of a darker green colour, and more delicate flavour. This variety was on trial this season at Chiswick and was given an award of merit. Another, but larger Cabbage well adapted for winter is Christmas Drumhead. This, like St. John's Day, is a very dark-leaved variety, solid, and similar in quality to the above. Those who grow either of the above would prefer them to other vegetables of a stronger nature. There are other advantages. Frost does not injure them, caterpillars rarely infest them, and they can be grown in a limited space. I think them more valuable than Savoys. To get a supply for the first three months of the year I sow in June and July. In cold, late districts it may be necessary to sow in May, and one sowing will suffice. The St. John's Day I sow early in July, having a liking for the small compact heads, large Cabbages not being required. Plant in rows 2 feet apart, the plants being 18 inches apart in the row. Grown thus they follow the Coleworts, and there is no break in the supply of good Cabbages from January to December.—G. WYTHES.

**Potato Windsor Castle.**—In the spring of this year I obtained a peck of seed of this Potato. Wishing to see what I could produce from this, this, I had the tubers cut, placing them in boxes in leaf-soil and standing them in a warm house. When they had rooted out into the boxes, I had them planted with a trowel on some land that had not been dug for more than fifteen months. The season previously it had been cropped with early Potatoes and Brussels Sprouts. Just before the Potatoes were planted I removed the stumps and hoed and cleaned the ground. The crop is a splendid one, there being  $3\frac{1}{2}$  cwt. of Potatoes. Another recommendation to this Potato is that it ripens off early. At the present time (end of September) I have a splendid crop of green stuff on the ground.—J. CROOK.

**Tomato Duke of York.**—This new Tomato will, I think, in a short time be as popular as the well-known Perfection. It sets as freely as one could wish in a moist temperature or in dull weather. Some seeds sent me late this spring have produced very fine plants with a great weight of fruit, and, though late, will be most serviceable, the fruit being of a uniform size. Earlier plants planted out of doors in June are now giving a heavy crop of ripe fruit. Another good point is the habit of the plants. They do not produce such long joints as some of the older kinds and there is less cutting back. It is the heaviest cropper I have grown, and I intend to grow it largely next season. When overfed, it, like most other kinds, produces large fruit, but when well managed I have found it one of the best as regards good shape and size of fruit.—G. WYTHES.

**Celery.**—The Celery crop looks very well indeed this year, but the very fine weather and long-continued drought will probably affect it badly unless extra trouble is taken to water it well before earthing up too much. Even with a change to wet weather too much dependence must not be placed on the rains being sufficient for its needs, and water should be given freely if good quality is desired. The advocates of early earthing are not so numerous as they were some years ago, and this is for the best, as once we get the soil high enough to form a ridge, there is no further chance of effective watering. A little soil put to the plants when they begin to spread is a good thing, but after that the best practice is to add no more until six weeks or so before wanted for use, as this gives plenty of time for blanching. Later on, say from the middle to the end of October, earthing up of the main crop may be pushed forward in good earnest, especially if a large quantity is grown, as we must then take all the advantage of suitable weather; but with small quantities grown for private supply only I would advise leaving the work as late as is consistent with the requirements, being quite convinced that late earthing conduces to hardness, the hearts resisting hard frost all the better for not having been too long in a blanched state.—J. C. TALLACK.

TREES AND SHRUBS.

CEDARS OF LEBANON AT HOME.

We publish this week a carefully done engraving of one of many photographs taken by M. Maurice de Vilmorin this year, when we also had the pleasure of seeing these trees on a mountain in Algeria—Mount Babor—about the time when the Hawthorn opens on the mountains in North Africa as well as in our English hedgerows, and with the snow still in wide wreaths in the hollows of the higher parts of the mountain. A description of the visit, however, has been already published on page 443 of THE GARDEN for June 22, 1895. To this we beg

there is not the same quantity of bloom as at the first flowering. If this has a fault, it lies in the direction of excess, as I have often felt in the presence of magnificent specimens clothing areas of from 200 to 400 square feet we cannot see the beauty of the flowers, nor mark their perfect harmony with the foliage because of their sheer massiveness; hence the more sparse harvest of beauty spread over August and September is thus more welcome and graceful. Seldom has the autumnal harvest of beauty been richer and more plentiful than this year. It is quite true, as noted by "F. W. B.," that the Wistaria is slow in starting. But against this should be placed to its credit that once it does start, no harsh or cruel treatment nor the hardest starvation treatment can prevent it blooming in spring and autumn. Much of the stubbornness at starting arises from the hard régime adopted in a young state. Beautiful as the Wistarias are and deserv-

CHRYSANTHEMUMS.

CHRYSANTHEMUM NOTES.

At the first sign of colour in the buds it is wise to place the plants under cover, or the bad effects of the open air will be noticeable in damaged florets. On the other hand, it is not a good plan to begin housing Chrysanthemums for any other reasons except the above and protection from frosts. I have sometimes put backward sorts under glass for the purpose of hastening their blossoms. This, I am satisfied, it does not do until after a certain period. The night dews and the generally moist atmosphere of the month of September are most conducive to bud-swelling, and there is no means under glass of providing this natural state of things. The

leaves miss it, failing, for a time at least, to do their proper work, and thereby giving a decided check to the upper portion of the plant. By placing plants under glass before the flower-buds have become well set, a soft attenuated growth will be observable, however cool and airy the structure is kept. Frequently, too, such positions as the vinery or Peach house are the only places available; here the leaves have not yet fallen and shade is over-abundant. A better plan to bring on late varieties is to take them from the bulk and stand the plants in the sunniest spot in the garden. Give them ample space so that the wind may help the other elements in ripening up the whole of the plants' growth. To obtain blooms in perfection one likes to see the top leaves and buds well developed and hardened.

Meantime, there is much to do in the way of preparation for the flowering quarters. It is well to be ready, as it sometimes occurs that frost compels the housing to be done in a hurry. Necessary cleaning should be done, and although good Grape

growers will not strip their Vines of leaves for the sake of Chrysanthemums, superfluous growths and leaves may be cleared. There is no harm either in taking away some of the lower leaves from the Chrysanthemum stems; these soon decay when the plants are placed together thickly under glass. At housing time, again, we may prevent the spread of mildew by dusting with flowers of sulphur. It is the undersides of the leaves which are generally most affected.

The arrangement under glass will be carried out according to convenience and individual taste. Some idea of a good home show should of course be thought of, even when the plants are intended to produce blooms for exhibition. Japanese Chrysanthemums, however, should be stood in the warmest quarters. These open their peculiarly-formed blooms more freely in a warm temperature (from 50° to 55°), but a cooler atmosphere is better for the incurved sorts. They reflex their petals in strong heat instead of curling inwards, and thus spoil the formation so desirable. The Japanese varieties, again, will mostly bear the rays of the sun

Cedars of Lebanon in North Africa (Mount Babor, Algeria). Engraved from a photograph by M. Maurice L. de Vilmorin, May 3, 1895.

to refer any reader interested in this noble tree as it grows in a wild state.

WISTARIA SINENSIS.

"F. W. B." (p. 157) refers to the frequent use of Wistarias as crowning ornaments to walls in France. They are also all too seldom used for such purposes in this country. Few things in gardens are more beautiful or satisfying than walls of Peaches, Pears, Figs, and Tea Roses crowned with a canopy of Wistaria sinensis in flower or foliage. Fortunately, the leaves and branchlets are unique in form, colour, and cleanliness. I cannot remember a case of insects on the Wistaria in the open air. The leaves, flowers, and young shoots on healthy plants are also ample for protective purposes, and their character adds greatly to their force and efficiency as protectors against cold on the bare face of walls on still, frosty nights. Thus for a living coping we have few plants that can equal the Wistaria, while none can possibly excel it in beauty.

I am surprised that more is not made of the autumnal blooming of Wistaria sinensis. True,

ing of a place in every garden and on every house, how rare is it to find masses of young plants in robust health in even our best nurseries. Instead of this, a few small plants in pots, with a starved look and in stunted condition, represent the entire stock of this matchless climber. More than most plants, perhaps, when Wistarias get into a low way, they are a long time getting out of it; and hence mainly the slowness of this start.

There is another reason for slow growth at first. Any soil or culture, or rather no culture, is considered good enough for Wistarias. But for vigorous shoots of 10-feet, 20-feet, or 30-feet run to be quickly wreathed with blossom, and continue in health and beauty for a lifetime, the Wistaria prefers a yard deep of light rich loam resting on a dry base, enriched with well-rotted manure or leaf mould, and drenched with sewage or house slops in dry weather.

Of course I shall be told that not a few of the finest specimens of Wistarias that have flowered the most and run the furthest have never had any culture or manure. I know it, and yet who shall say what their deep-boring, far-reaching roots find for themselves. D. T. F.

better than the incurred sorts. Exceptions to this rule may be made in the case of such dark varieties as William Seward and G. W. Childs, as well as the bronzy-coloured Col. W. B. Smith. These sorts readily decay through the sun shining on the florets whilst damp, caused by the condensed moisture of the night. It is well, therefore, to guard against this by putting the sorts named—and, in fact, any which show the least signs of decay—in the more shady parts of the greenhouse. I have already intimated that it is unwise to leave any plants in the open air after the flower-buds show colour, and it is seldom safe to leave any outside after the first week of October unless protected. The appearance of frost varies in most localities, high and dry positions being understood to escape frost more readily than low, damp ones. When first placed under glass, after being accustomed to the outside air, Chrysanthemums appear to stand still in their growth, as it were, for a few days. At this time great care is needed, especially in the matter of supplying water. In the first place, if the weather be fine it is advisable to damp the paths and also among the pots, but to keep the roots on the dry side. To give them the constant supplies they have up to now received out-of-doors would assuredly lead to disastrous results. In a short time, however, tiny roots will be observed at work on the surface of the soil, then more moisture will be required in the pots, the plants having become used to new conditions. The unfolding florets will tell us that it is advisable to throw less water about the houses, and in fact from this time everything should be done to assist a dry atmosphere. The necessary watering should be done early in the day, so that all may be dry by the evening. Give air abundantly at first by keeping doors and ventilators open, but decrease the amount as the flowers develop. I would not entirely close the top ventilators except to keep out fog, and just a little air passing through from the front will keep the conditions favourable to the opening blooms, with fire-heat according to the weather. I do not favour a constant shade, but if possible I would keep the early morning sun away by the use of some temporary material. It is at this time when most of the damping in the blooms takes place. The plants are cold and moist, having passed through long hours of darkness, and the bad effects of sunshine are quick unless the temperature can have been previously warmed and dried by heat and air. Until this takes place the use of shade is apparent. Decayed petals should not be left on the flowers; disease soon spreads, and the insect pests must also be watched. Green-fly is the most troublesome. Guard against the spread of it by fumigating with some tobacco preparation when the plants are first housed. The pest is generally abundant under the leaves and is unnoticed. If destroyed early the blooms will be safe. When once green-fly gains a foothold, as it were, in the many folds of a flower, there is great trouble in getting rid of it without spoiling the blooms.

The use of stimulants should be continued up to the time the flowers are nearly fully open. I would, however, advise caution in the use of sulphate of ammonia. The idea that this powerful salt is the one thing necessary to give "finish" to the flowers is still strong, but by over-doses of it many Chrysanthemums are annually ruined. When sprinkled on the surface it is absolutely dangerous. The better plan is to use it in such liquids as cow manure at the rate of an ounce to four gallons. H. S.

**Chrysanthemum Queen of the Earlies.**—This English raised Japanese Chrysanthemum

is most promising in its appearance as a September and early October flowering variety. The blooms are of large size, having long slightly incurving florets of medium width, making a large and massive bloom. When fully developed the petals are somewhat irregular in form. The colour is ivory white, the centre tinged with primrose, which passes off with age. —E. MOLYNEUX.

**Chrysanthemum Mme. Eulalie Morel.**—For providing cut flowers in quantity at a minimum of cost in labour or for making a display in the open borders when so many of the ordinary occupants have faded, this Chrysanthemum ought to be cultivated. It belongs properly to the Japanese early-flowering section, as it has all the characteristic points about it of this quaintly formed type. The colour is striking, being cerise with a golden suffusion, the reverse golden.—M.

**Chrysanthemum Roi des Precoces.**—This early-flowering variety is the finest of all the dark-coloured sorts for the open border. From the middle of September it will blossom with freedom until the end of October, should it escape frost. In colour it has a specially dark and velvety appearance, harmonising so well with the Mme. Desgrange trio of white, yellow, and primrose. The habit of growth, too, is all that can be desired, as it grows from 2 feet to 3 feet high.—E.

#### NOTES ON CULTURE.

PREPARATIONS will shortly have to be made for housing the plants. The fast unfolding florets of such varieties as Avalanche, Miss Anna Hartshorn, Commandant Blusset, Duchess of York, Col. W. B. Smith, and Louise warn us that the night dews now experienced must prove harmful to the development of these early blossoms. After September 20 those who reside in a low and necessarily damp situation are not secure from an early autumn frost. Where Chrysanthemums are cultivated to produce large blooms, whether for exhibition or otherwise, some plants are sure to be more forward in the development of their blooms than others. It is not possible, of course, to sufficiently retard the plants now opening their blooms to enable the cultivator to employ these in November. Instead of allowing the expanding buds to remain out of doors and be spoilt, I prefer to house the plants the moment the colour of each variety is discernible, so that the blooms may be enjoyed even if this be early in October. If it is not convenient to place the plants under cover for a few days after the first florets burst, strips of brown paper cut 3 inches wide and sufficiently long to allow of one end being tied to the peduncle, bending it over the opening bud arch fashion, securing the opposite end also to the peduncle, will give protection from rain, night dews, and shade during the day. The bulk of plants grown for exhibition will shortly also require placing under cover. Inexperienced growers of Chrysanthemums do not understand at what date to house their plants so as to have them in bloom at any given period. Without some knowledge as to the length of time particular varieties require to develop their flowers it is extremely difficult to have the plants in perfection exactly when wanted. The flower-buds of some varieties require a much longer time to develop after they reach a certain stage than those of others. Circumstances do not sometimes admit of the plants being housed at exactly the time wished. If the tender swelling buds should be injured by an early frost in a damp locality, the blooms cannot develop evenly and well. It is not wise to leave plants out of doors without protection of some kind in any district after October 8. Housing should commence the third week in September, removing the very early plants, as previously stated, and those with late or backward buds.

The Princess Teek varieties will illustrate quite well my meaning. These require much longer to

expand their blooms fully than any others. Take, again, Princess Victoria in the Japanese section; this is naturally a late-flowering variety and needs more time for expansion. Such as the Queen of England family and Mlle. Thérèse Rey in the Japanese section develop rapidly, the former requiring not more than three weeks after the first petals commence to unfold. Where facilities exist for dividing the plants into three batches, say early, medium, and late, for the purpose of housing and after-treatment, so much the better, as each block, as it were, could then have the particular form of treatment required after the plants are placed under cover. From the foregoing, beginners may learn a little of the requirements necessary in Chrysanthemum culture for exhibition, as it is useless to have only a portion of the varieties in perfection at any particular date. The cultivator who manages his plants in such a manner that all are expanding regularly and well has a much better opportunity of winning prizes, or even of obtaining a thoroughly good home display of large, perfectly developed and formed blooms.

All plants before housing should be made quite clean and free from insect pests. The latter are by far the more troublesome to get rid of. It is useless to house the plants affected with mildew, as it is sure to spread under the favourable conditions of a lack of air and additional atmospheric moisture. No plan is so good as thoroughly wetting every leaf on both sides with the lime and sulphur mixture so often recommended in THE GARDEN. The plants should be given as much space as possible when placed under cover, admitting abundance of air to the plants both night and day. Should the weather continue dry and warm after the plants are housed, they should be syringed overhead at least once daily, say about 2 p.m. A more humid atmosphere will thus be obtained, maintaining somewhat nearly similar conditions to those enjoyed by the plants out of doors. Extremes of both drought and moisture in the air, as well as at the roots, are not favourable to successful Chrysanthemum culture.

E. MOLYNEUX.

#### SHORT NOTES.—CHRYSANTHEMUMS.

**Chrysanthemum Montague** belongs to the Japanese section; the peduncles are both erect and stiff, rendering it useful in a cut state. The colour is rich purple-crimson, intensified when opened under glass. It grows fully 4 feet high.—S. P.

**Chrysanthemum Vicomtesse d'Avene** is a desirable September-flowering variety. The habit is dwarf and stout. The blooms, somewhat incurved, of a pink-lilac shade of colour, are freely produced on long stiff stems, and are thus useful for vase decoration.—E. M.

**Chrysanthemum Arthur Crepy** is perhaps the finest yellow-flowered out-of-door Chrysanthemum we have in cultivation. The flowers are borne on stout foot-stalks, the colour primrose-yellow fading to white round the edges. The habit of growth is desirable, being upright.—M.

**Chrysanthemum Duchess of York.**—The present appearance of the plants of this charming Japanese Chrysanthemum betokens some grand blooms, not only in November, but during the month of October. Several buds here are now unfolding their long twisting florets, showing the pleasing soft hue of yellow.—E.

**Tufted Pansy Charm.**—Mr. A. J. Rowberry is perfectly right when he says that this variety received no special recommendation at the Viola conference held at Birmingham August 3, 1894. Nevertheless, the mention of this variety, together with the confirmation of its raiser's remarks by several speakers in the report of the conference, induced one grower at least to grow it this year, and to anticipate a valuable addition to bedding Violas. The result is disappointing. Every word written against it by "H." is richly deserved; he in fact gives it more praise than it deserves when he compares it to such va-

rieties as Mrs. H. Bellamy or Archie Grant. These may have their faults in growth, but I hold they are compact growers compared with Charm, to say nothing about the quantity of flowers we get from these compared with the scanty display made by Charm.—W. BAXTER, *Woking*.

ORCHIDS.

DENDROBIUM CHRYSOTOXUM.

THE accompanying illustration faithfully depicts what is evidently a good variety of this beautiful Orchid, one of the best of the evergreen section. As garden plants there are very few Orchids to

March or April. After the blossoms are over the plants commence to grow from the base of last season's growth, and they should then be potted if this is necessary. The pots need only be large enough to take the plants comfortably. They should be drained about three parts of their depth. Cover the drainage with a film of Sphagnum and press this in evenly all round so that the earthy parts of the compost are not swilled out among the drainage. Good peat fibre and Sphagnum in equal proportions and plenty of rough lumps of charcoal or potsherds will make a good rooting medium, and this must be bedded firmly about the roots in order to keep the plants from swaying. The base of the leading pseudo-bulbs must be

also abundance of sunlight, in the brisk temperature thus formed the pseudo-bulbs almost visibly distending. By the end of July or early in August the season's growth will usually be finished, when more air and less heat will be necessary to harden and ripen this. This is impossible in the house where grown, so the plants must be taken to a cooler, more airy structure, or if such is not at command they may be placed out-of-doors, shading for a time in the middle of the day, but afterwards allowing full exposure to all weather excepting very heavy and long-continued rains. By the end of August or soon after, they must be placed under cover, as the nights are usually very chilly in September. Just enough water must

*Dendrobium chrysotoxum.* From a photograph by Lord Annesley.

beat this, the flowers being remarkably rich in colour, useful either for cutting or the plants for grouping, while its culture does not present any great difficulty. There must, it is true, be a proper system followed with it, and it must be kept to its proper annual routine of growth, but this may be said of any Orchid, or indeed any plant. *D. chrysotoxum* is a native of Moulmein, where so many beautiful species of the genus are found. The pseudo-bulbs are each about 9 inches in length, and the arching graceful spikes are produced from nearly the top of these when two years old, occasionally on the new growth. The blossoms are rich golden yellow, the lip having a deeper tint with occasional streaks of maroon. This is downy and lightly fringed, and the flowers usually open in

kept rather above the level of the rim of the pot, and the compost trimmed off neatly to prevent accumulation of moisture about the base of the stems. Great care will be needed in bedding the compost not to snap off the little shoots, for at this time they are exceedingly brittle. When the plants are returned to the growing quarters these growths must be carefully watched, as a little too much water or bright bursts of sunshine may cause the loss of many of them. Only enough water to keep the moss green will be needed at this time, but the syringe must be often plied about the pots in bright weather to keep up the requisite atmospheric moisture. Plenty of heat being afforded, they will make very rapid progress, and as the roots extend more moisture will be required and

now be given to keep the pseudo-bulbs from shrivelling, and the night temperature must be kept as near 50° as possible all through the winter. This conduces to a long rest and is a most important detail. No great excitement is needed in spring, the spikes generally showing freely in February and soon coming to maturity. The chief insect enemies are red spider and a small white scale, but these are not usually troublesome, and with ordinary vigilance may be kept under. *D. chrysotoxum* has been in cultivation since 1845. R.

**Trichosma suavis.**—This is apparently very erratic in its time of growing and flowering, a plant that bloomed in March having made another flowering growth during the summer, and now

the blossoms are just opening. The only fault with this is there is not enough of it, for the flowers are extremely pretty. They are produced on short racemes from the apex of the stems, and the sepals and petals are narrow and white, the lip being yellow in the centre, marked with lines of brownish crimson. The roots of this plant are large and somewhat fleshy, and the compost should be used in a rough open condition. Three parts of peat to one of Sphagnum Moss will grow it well, and only a thin layer is required over good drainage. A cool, moist atmosphere all the year round and plenty of water at the roots must be given while growing. During winter less is required, but at no time must the plants be quite dry. It is a native of the Khasia Hills, having been introduced in 1840.

### SEASONABLE NOTES ON ORCHIDS.

No better weather could be desired by Orchid lovers than that of the past few weeks, the continued sunshine serving to ripen up the growth in all the houses and to bring on the later plants rapidly. Dendrobiums, Cattleyas, Catasetums, and the like have especially benefited by the fine weather, for these, of all Orchids, delight in abundance of air at this season, and this has been possible without lowering the temperature. Though the days are fine, the nights are getting longer, and fire-heat has now become absolutely necessary, not a harsh dry heat, but the pipes kept nicely warm, and a little chink of air on the top of the house to keep the atmosphere moving. This does away with a good deal of drip, which sometimes gives trouble now. Among the Dendrobiums that have finished growing are *D. aureum*, *crassinode*, *nobile*, *Wardianum*, *Pierardi*, and most of the short-bulbed evergreen kinds. *D. Bensoniæ*, *D. Brymerianum*, and several others are nearly done, while a few of the later kinds are still in full growth, but as these latter do not flower upon the new pseudo-bulbs, this is not of so much consequence. The popularity of *D. Phalopsis* is increasing yearly, and small wonder, for it is a truly magnificent species. Not only are the new growths throwing up from the centre almost before the last leaves are fully developed, but old dry-looking stems from which one would hardly expect flowers are also contributing to the display just now beginning. Deciduous *Calanthes* require careful watering now that the spikes are appearing, and these must not be wetted if it can be avoided, especially *C. vestita*, the flower-spikes of which are very easily injured. *C. oculata gigantea* requires more water than the *Veiteli* and ordinary types of *vestita*, but even here care is necessary. In fact, nearly all Orchids are now requiring diminished supplies, the amount of diminution varying of course with the various kinds. *Saccolabiums* and *Aerides* are as yet showing no signs of going to rest, the great fleshy roots—rambling over large pieces of charcoal, and in some cases leaving their pots or baskets to lay hold of the stage—being as yet quite green at the points. *Angraecum eburneum* is throwing out its stiff-looking spikes that will help presently to brighten up the winter months and last long into the new year. *Cypripedium Charlesworthi*, too, in its varied forms is on the move with me, the beautiful broad dorsal sepal standing out distinctly from the rest of the flower and giving it a very unique appearance. This is certainly a great acquisition, and cannot fail to become popular as its merits become better known. In the *Cattleya* house *C. labiata* will soon be a host in itself, following, as it does, close on the heels of *C. Gaskelliana*. *C. bicolor* is of quite a different

type of beauty to these, but well worth a place on account of its distinctiveness: as also is *C. velutina*, another prettily marked species, the flowers of which have the additional recommendation of being very sweetly scented. A steady temperature must be kept now in this house, excitement at this season being dangerous to the health of the plants. Plenty of water is required as yet by such as *C. Leopoldi*, *C. granulosa* and a few more that root freely at this season, but for the majority less will suffice, those that have flowered upon the current growth especially. It is not yet too late to give new compost to any that may require it, though it would have been better done before this; still, there need be no fear if the plants are not unduly disturbed, and it will be found preferable to keeping them in a close or sour condition all through the winter. In the cool house we have been busy surfacing *Odontoglossums* and repotting any that needed it. The amount of water that these Orchids require soon soddens the best peat, making it an unsuitable holding for the roots, and it is not unusual for plants repotted in spring to want a little attention again in autumn. The slugs are already busy among the advancing spikes, and close watching is necessary. *O. grande* and its allies are especially attractive to these pests, and I always take the precaution to raise the plants upon inverted pots in saucers, first dipping them all and allowing them to remain in the water till any insects that may be lurking in the compost are expelled. *Oncidium macranthum* has finished its growth, and the plants should be stood close to a ventilator kept open day and night in order, if possible, to induce a short rest before the growths start. More care is now needed in damping between the pots not to splash the surface of the compost, or it is very difficult to determine the real state of the roots for moisture. A little of the Sphagnum may also require to be pulled out from around the base of the pseudo-bulbs of small plants, as it is apt to hold moisture to excess. The temperatures as given last month will still be right, but the warm house will not run quite so high by sun-heat, and less shade will be needed in the cool house. Keep a sweet atmosphere by frequently scrubbing the stages, pots, &c., and allow no litter to accumulate about the houses, as, besides having an untidy appearance, this harbours insects of all kinds.

II. R.

**Masdevallia Davisii.**—The distinct colour—a pretty bright orange—of this *Masdevallia* makes it worthy of a place in all collections. In addition to this, it is a free-flowering and easily cultivated species, thriving well in a cool house. The usual treatment as recommended for the showy flowered kinds suits it admirably. The flowers, produced singly on the scapes, are each about 1½ inches across the sepals. It is a native of Peru, and quite an acquisition to the genus. It was introduced in 1875.

**Zygopetalum Gautieri.**—This fine species is now in flower, the elegant racemes being very very attractive at this dull season. These bear about six flowers, the sepals and petals of which are green, with heavy blotches of chocolate-brown. The lip is narrowed near the column, spreading in front, and of a pretty purplish blue, the colour being intensified at the crest and fading to nearly white upon the edge. Somewhat resembling *Z. maxillare*, *Z. Gautieri* is a better grower than this kind, and also bears larger flowers. It thrives in shallow baskets or on rafts with only a little compost about the roots and good drainage, but possibly the best way to grow it is on Tree Fern stems. I recently saw a fine plant flowering freely in this manner. The roots under this mode of treatment have something to lay hold of as they grow; whereas

in baskets or pots the long rhizomes soon out-grow the space provided for them. *Z. Gautieri* is a Brazilian Orchid introduced in 1868, and thrives well in a *Cattleya* house temperature. If given more heat than is here afforded, especially during winter, it is very apt to fall a prey to thrips.—H.

**Cypripedium amandum.**—Though not so showy as some kinds, this is, nevertheless, a pretty and interesting hybrid, of easy culture and very free growing. Its parents are *C. isigne* and *C. venustum*, and it may be described as having flowers fairly intermediate, with foliage inclining more to that of the former parent. The dorsal sepal is light green in ground colour, with stripes of a deeper colour and a few spots near the base. The petals are brown on the upper portion, greenish yellow below, also spotted with purple. The pouch is light green veined with a deeper colour, and much resembles that of *C. venustum*. The present is its flowering season, and it thrives well in an intermediate house.

## FRUIT AND VEGETABLE CROPS.

### MIDLAND.

**Chatsworth, Derby.**—The fruit crops generally in this neighbourhood, considering the very severe winter we have had, are very satisfactory, and but for the late spring frosts there would have been an abundance. Strawberries above the average and very fine. Bush fruits plentiful. Raspberries a failure. Cherries an average crop, but smaller than usual owing to the dryness of the season. Apples and Pears under average. Plums and Damsons scarce.

All kinds of vegetables did well excepting kidney Beans, which were all cut down with the frost and had to be sown again. Potatoes are looking very well; early kinds not so good as usual, but late kinds give promise of an abundant crop, no disease having shown itself at present.—W. CHESTER.

**Gopsall Gardens.**—The year 1895 will long be remembered for hard frosts and prolonged drought. The frost did much damage to many and varied plants. This is most noticeable, where the plants or trees have reached a good age, by branches or limbs dying away. Peaches and Apples have shown this more than usual this season; also Raspberries, Gooseberries, Currants and Morello Cherries. No doubt, also, the dry season following so severe a winter has had much to do with it, and had we had a genial season, things generally would have looked better, although on young vigorous trees and plants the fruit crops are above the average. Peaches and Nectarines are carrying a full crop, although later in ripening than usual. Strawberries above the average in size and quantity on one, two, and three-year old plants. Apricots a failure. Morello Cherries above the average in size and quantity. Gooseberries and Red and Black Currants above the average. Raspberries average. Apples a good crop, and promise well now we have had copious rains, which were much needed. The trees most loaded dropped a good number of fruit during the drought, but a full crop now remains in most parts of the neighbourhood. Pears a good crop. Plums above the average, especially those trees on walls and growing in a good sound loam; on standards a light crop, but fruit good.

The vegetable garden is now looking well, thanks to the welcome rains, and most crops promise well for autumn and winter. In the early part of the season we were much troubled with the Cabbage fly, especially on the Cauliflowers. Peas not so good, having suffered much from thrips; but later varieties—especially *Ne Plus Ultra*—look promising. The early Potatoes are below the average, owing chiefly to the severe check received on June 21, when many Potatoes, with other things, were cut down by frost in this

neighbourhood. Late Potatoes look most promising, as do also most other crops.—J. LEE.

**Orton Longueville, Peterborough.**—The crop of fruit this year is a very fair average. Small fruits, such as Strawberries, Currants and Gooseberries, have been abundant, and aphids and red spider have not been so troublesome this season. Many kinds of Apple trees have good crops, particularly King of the Pippins, Cox's Orange Pippin, Lord Suffield, Warner's King, Striped Beaufin, Baldwin, Keswick Codlin, Alexander, Northern Greening, Brabant Belle-fleur, and a few other kinds. Pears are much below the average, as was to be expected after the heavy crops of 1893 and 1894. A few, however, are bearing well, such as Doyenné d'Été, Orange Bergamot, Vicar of Winkfield, Crassane and Beurré Bosc. Nuts only a partial crop, but Quinces good. Many kinds of Plums on walls are bearing well, but trees in the open much below the average. Apricots are a fair crop; also Peaches and Nectarines; but the crop is not so heavy as in 1894.—A. HARDING.

**Warwick Castle.**—The Apple crop this year is the finest I ever remember: the severe winter and cold spring retarded the blossoms till the most dangerous frosts were over, the result being a remarkable set. Shortly after the young fruits were formed a period of dry weather set in; this caused many to drop, and both trees and remaining crop are all the better for it. The trees are very heavily laden with clean, healthy-looking fruit likely to attain a good size. Pears are also very abundant, early varieties rather small, later ones promise to be of average size. Plums average; the extraordinary crop obtained last year weakened the trees too much to admit of their carrying a heavy one this year; at least such is my opinion, which is confirmed by an extensive market grower in the neighbourhood. This grower's trees were last year caught by a severe frost when in flower; consequently his crop was a failure. This season, however, his trees are loaded with fruit, though such is not the experience of the majority of neighbouring growers. Cherries other than Morellos are not much grown in the district; these latter are a heavy crop. Peaches and Nectarines average. Apricots in many instances a failure. Small fruits extremely abundant and very good. Strawberries exceptionally abundant and good where the soil is somewhat heavy. There is, however, a good deal of light soil in the neighbourhood, and in the gardens where timely waterings could not be given the fruits were small, and many of them failed to swell.

Early Potatoes rather small, but sound and of fine quality. Early Puritan has given us by far the best crop of fine tubers. Late varieties promise to be a fine crop in every way; no trace of disease at present.—H. DUNKIN.

#### SCOTLAND.

**Coltness, Wishaw.**—In reply to your inquiry regarding the condition of the fruit crops in the gardens here and neighbourhood, I have much pleasure in stating that these are both abundant and good this season. Early Strawberries suffered somewhat from drought on dry situations, but the crop on the whole has been good nevertheless. Gooseberries are a more abundant crop this season than for many years past. Red Currants and Raspberries plentiful, as also are Black Currants, but the fruit of these is small owing to the dry summer. Pears and Apples are also bearing well.—J. GRAHAM.

**Terregles Gardens, Dumfries.**—Owing to the severity of the past winter and spring fruit trees were late in flowering in this district, and the weather being favourable there was a good set of all kinds of fruit. In spite of the dry season the crops are generally over the average. Apples are a splendid crop, the fruit large and well coloured. Pears are also a heavy crop and promise to finish well. Plums on wall a good average crop, standards thin, except Victoria, which is good. Cherries average. Strawberries in some

places suffered from the drought, but where watered and well mulched, the crop, especially on young plants, was an enormous one, the fruit large and flavour good. Raspberries, Gooseberries and Currants were heavy crops.

Early vegetables were very unsatisfactory: successional crops are doing well.—ALEX. CHALMERS.

**Urie, Stonehaven.**—Fruit crops here and in the neighbourhood are quite up to the average. Apples a little under the average. Pears an average crop, but small, as the weather in June was too dry for them. Cherries a good crop, but owing to such a quantity of wasps this season we had to pull them too soon. Strawberries an extra fine crop and of excellent quality. Gooseberries above average. Red, White and Black Currants heavy crops. Raspberries are abundant and large this season. Victoria Plum is the only one worth planting.

Vegetables in general have done very well, Peas extra well, but spring-sown Cauliflower has been a failure in most cases owing to clubbing. We escaped the severe winter wonderfully, only a few shrubs having died. The rain came in June just in time to save our crops from being utterly burned up.—A. REID.

**Whittinghame.**—Fruit crops are, as a rule, very good here this season, rather over the average in most cases. Strawberries suffered somewhat from the drought, the early varieties being rather small, but late sorts have been large and abundant. Apricots are with me almost a blank, though this is not generally the case in this district. Outside Peaches are also very scarce. Pears and Plums are under average. Apples a very heavy crop, and clean and healthy looking. Cherries, both sweet and Morello, an abundant crop; so also are Raspberries, Red, White, and Black Currants, and Gooseberries. I have tried Plums here as orchard trees, but without any success; even Victoria refuses to fruit unless upon walls. The sorts I grow are Green Gage, Golden Gage, Kirke's, Jefferson, Washington, Golden Drop, &c. Jefferson and Golden Gage are usually the best flavoured we have. I have not tried any of the newer sorts.

Kitchen garden crops of all kinds are very good this season. Peas extra, Potatoes good, and as yet showing no signs of disease. Field Potatoes never looked better than they do at the present time. We have had abundant rains lately, and crops of all sorts have been greatly benefited thereby. The only crop which shows any deficiency is the Turnip where it had to be re-sown, but, fortunately, this was not very general in this quarter. I am glad to say that there has been comparatively little damage done to shrubs, &c., by the past severe winter, although upon two occasions the temperature fell to zero. Our large Eucalyptus suffered to the extent of losing all its leaves, but they have been again replaced by a most luxuriant growth. One result of the check received has been that a large quantity of young shoots have broken away upon all parts of the old trunk, so that it is now better furnished than ever it was before. Several other varieties of Eucalypti which we had on trial were killed outright, including a plant of *E. coccifera* ten years old. On the other hand, such plants as *Aucuba japonica* were not in the least injured. *Garrya elliptica* (in the open) was very slightly injured. The only shrubs we have seriously injured were some very old plants of *Laurus nobilis*.—JOHN GARRETT.

**Taymount, Broughty Ferry.**—The winter of 1895 will long be remembered for its destructive frosts. Here the thermometer fell 4° below zero on four consecutive nights. I have seldom seen fruit trees so laden with bloom as they were this year, but since then the drought has materially affected fruit trees, and had it not been for the showers we had, the Apple and Pear crops in this district would have been under the average both in size and quantity. They are now gaining in size rapidly, but the crop will be a light one. Peaches and Nectarines are not much grown out of doors in this district. Small fruits of every

description have been abundant and good. Strawberries have not been so fine for years. Vicomtesse H. de Thury is the favourite in this district.

The drought has had a singular effect upon vegetables, but since the rain came they have made quite a rush into growth. Potatoes are good, and up to now show no sign of disease.—ANDREW SMITH.

**Glamis Castle, Glamis.**—Generally speaking, the fruit crops in this district are above the average. Apples, Pears and Plums are very good. Cherries and Gooseberries are somewhat small, owing to the drought in the early part of the season. Strawberries and other small fruits were very fine. The severe frost in winter killed Raspberry canes in some cases to within 1 foot of the ground, and Gooseberry bushes died owing to the continued drought in May and June.—THOMAS WILSON.

**Tynninghame, East Lothian.**—While fruit as a whole is a good crop, small fruits without exception have been above the average, and of these Gooseberries alone have suffered from drought. The intense frost appears to have passed away without leaving any bad effect on out-of-door fruits. Among the larger fruits Plums are undoubtedly the crop of the year. Figs and Apples are also up to the average, while Pears, Peaches and particularly Apricots are very deficient. Since the break up of the drought, fruit has swelled rapidly, and with a good autumn, winter Apples and Pears may be expected to be of extra quality.

With regard to vegetables, the season has been fairly good; the frost, indeed, left little green stuff, all the Broccoli having been killed, with the exception of Sprouting and Carter's Universal, and Spinach late in starting. But what had every appearance of being one of the latest seasons proved instead one of the earliest. Early Cauliflowers and Peas I have never seen so early or finer, and had it not been for a scourge of maggots amongst Cauliflowers, Cabbages and Onions, the season would have been an extra good one. Potatoes are a splendid crop. In the quarters set apart for flowers, many Montbretias, Gladioli, Hyacinthus candicans, Tritomas and Alstroemerias were killed. In some gardens Carnations have failed, and Pentstemons, Calceolarias and other half-hardy subjects were all but destroyed. Bedding plants in general are not so good as usual, though Roses of all sections have been wonderfully fine.—R. P. BROTHERSTON.

**Murthly Castle, Perth.**—The crop of fruit in this district may be considered a good average. Apples are a fair crop both on standards and wall trees. Plums, including such varieties as Kirke's, Jefferson, all the Gages, and Coe's Golden Drop, are heavy crops. Pears fair. Cherries (Morellos) a heavy crop, clean and good. Small fruit, Gooseberries, Red and Black Currants over the average. Strawberries fine, although the earliest suffered from want of moisture. Raspberries a good crop; the canes suffered from the severe frost of last winter.

Vegetables of most sorts are looking well, with the exception of Cauliflowers and Onions. Peas are grand. Potatoes a heavy crop, no disease, but I fear, with so much rain, it will begin to develop soon. Our winter vegetables got severely crippled, scarcely a green thing being left, except Cabbage, which was protected with snow. The summer so far has been marked by extremes of heat and cold.—JAMES LAURIE.

**Balcarres, Fifé.**—The fruit crops in this district are very good. All small fruits are exceptionally good both in quality and quantity. Apples a fairly good crop. Pears fair. Plums very heavy. Peaches good. Cherries very good, particularly Morellos.—EDWARD TATE.

**Larbert House, Stirling.**—The very severe winter we experienced here apparently has had no bad influence on fruit trees and bushes. The Apple crop has not sustained the fine promise of the spring. Bloom was everywhere abundant and gave promise of a full crop, but the long spell of dry east winds, powerful sun, and continued drought brought on a plague of caterpillar, aphids,

&c., that completely did for the crop; some trees, indeed, nearly succumbed entirely, and it was only by repeated syringings with strong solutions of black soap, paraffin, and hellebore that our trees were saved from absolute ruin. Apples on walls are fairly good, and one or two pyramids. Pears on west walls are good. Plums on walls are abundant and above the average. Peaches and Nectarines are all grown under glass and are good. In some places hereabout Peaches, where grown on the open wall, are a fair crop, but a continuation of this damp weather I am afraid will be fatal to ripening. Cherries here have been plentiful. Strawberries have been abundant and good. Blackberries, Red Currants, Raspberries, and Gooseberries have been grand, and everywhere round this district I am assured they have been the same.

Vegetables are now looking well, but in the early part of the season the whole of the Brassica tribe suffered terribly from the drought; indeed, I never remember a season in which clubbing has been so rampant as this.—DAVID AIRDRIE.

**Carron House, Stirlingshire, N.B.**—Fruit crops generally are over average and Apples are likely to be large as well as abundant. On the heavy land in the valley of the Forth vegetation suffered little by drought. Small fruits, Currants and Gooseberries especially, have been a very heavy crop and unusually large in size. Mulching protected them during the dry weather and the rains came in time to complete the crops. Strawberries were plentiful and of good size, but the drought shortened the fruiting period. President was an unusually heavy crop, for it is not surpassed for cropping in this locality. John Ruskin, though not of high flavour, was very abundant and makes a good preserving Strawberry. Aberdeen Favourite as a second early was good, and Duke of Edinburgh was large and showy with a fair crop.

Vegetable crops generally are very luxuriant. Potatoes have been early and of fine quality, but the heavy rains have changed them for the worse, but no disease has yet appeared. The frost (so severe during last winter) did no harm to fruit trees, but destroyed a number of common shrubs, Cupressus Lawsoniana especially. Roses on arches, Hybrid Perpetuals and Ayrshire suffered severely, but dwarfs did not.—M. TEMPLE.

**Darnaway Castle Gardens.**—Fruit crops this year very disappointing. Gooseberries, Black and Red Currants poor and very small. Strawberries an average crop, but of no flavour. Raspberries average. Apricots very thin. Peaches average crop. Plums a heavy crop, much smaller than former years. The following varieties we grow on walls: Early Orleans, Denniston's, Pond's Seedling, Kirke's, Washington, Magnum Bonum (yellow and red), Goliath, Coe's Golden Drop, Denbigh Seedling, Green Gage, Transparent Gage, Victoria. Pears a good average crop, but small. Apples below average and small. All fruits are smaller in the north of Scotland this year, partly owing to the wet summer and want of sun.

Vegetables did fairly well. Both early and late Potatoes are looking well, quality good and free of disease as yet.—D. CUNNINGHAM.

**Dunrobin Castle Gardens, Sutherlandshire.**—The fruit crop here may, on the whole, be classed as average. In the case of Plums, Apples and Pears the crop is somewhat irregular, some trees bearing a heavy crop and others but thinly furnished. The season here has been very different from that experienced in the midland and southern counties of England. Instead of the drought experienced in the south, we have had a rainy and comparatively sunless season. From June 4 to August 16 rain has fallen on forty-seven days out of seventy-three. We had a dry spell early in May, which was very troublesome for the germination of small seeds sown about that time, but, with that exception, 1895 has so far been rainy and dull. In some seasons the case is reversed, but it is rather surprising to find a long-continued drought in the southern portion of the British

Islands while most of the same period the northern portion was suffering from too much rain and dull weather. The last winter did little damage here. Although long continued, the ground was protected most of the time by snow, and being so near the sea, 17° of frost was the most experienced. Small fruits have been abundant and good. Elton Pine (still our best late Strawberry) is at this date (August 17) yielding plentiful gatherings both for dessert and kitchen use.—D. MELVILLE.

**Hopetoun House, Queensferry.**—Apples an average crop, Lord Suffield and Keswick Codlin being the best. Pears and Cherries on walls good. Plums on walls under average, standards (Victoria) very good. Apricots fairly good, fine size. Peaches scarce on open walls, extra fine inside. Nuts very few. Small fruit, as Currants, Gooseberries, Strawberries and Raspberries, abundant. Hardy fruit trees in general were well prepared to stand the severity of last winter, the wood being well ripened last autumn. The blooming season was all that could be desired, but the long spell of drought brought with it an abundant supply of caterpillars and also red spider, and was the means of spoiling a fair set of Apples of all kinds. Apples in particular were sadly crippled until we got the rain in the beginning of July. Since then the trees have assumed a more healthy and vigorous appearance.—JAMES SMITH.

**Cawdor Castle, Nairn, N.B.**—In Nairnshire we have had no such dry season as you have had in England. We had rain almost every day for six weeks. Gooseberries, Raspberries and Currants extra good. Too much rain for Strawberries. Victoria Plums on standards hanging like ropes of Onions and breaking the branches. Peaches and Apricots poor. Apples and Pears fair. The Victoria is the only Plum worth planting here. It is a sure bearer: Orleans bears now and again. For flavour, Green Gage, Jefferson and Golden Drop are the best.—JAMES MAITLAND.

**Lennox Castle, Stirlingshire.**—The fruit crops in the gardens here and neighbourhood are the best I have ever seen. Apples, Pears, Plums, and Cherries are extra good. Strawberries, Raspberries, Gooseberries, Red, White, and Black Currants are also an extra heavy crop. A good many Evergreens suffered. The dry spring has done very little harm to crops in this neighbourhood, but we have had a terrible plague of Onion and Carrot maggot.—J. TINSLEY.

**Alve, Clackmannan.**—The fruit crops are on the whole above the average. Peaches, Nectarines, and Apricots are an average crop. Figs stood the severe winter without protection and are now looking well. Apples an average crop. Pears, Plums, and Cherries are above the average; trees clean and healthy. Small fruits are abundant. Gooseberries a wonderful crop, although lacking in flavour, probably due to so much wet weather lately.—H. McDERMENT.

**The Gardens, Glenormiston, Innerleithen.**—The fruit crop in this neighbourhood is generally good, but it has suffered considerably from the dry weather, the soil in Peeblesshire being rather light on the whole. At Glenormiston we have a heavy soil on a clay subsoil. On that account we have secured good crops—I may say heavy crops, with the exception of Cherries, which are rather light. The Strawberry crop suffered considerably from frost early in June. Still we had a fair crop withal.

Potatoes suffered from the same cause, and I should say are the worst of all the vegetable crops. Early Turnips were attacked by fly to some extent. Other crops are all very good on the whole. As to the severe winter, I have noticed no damage whatever to any of the fruit trees; crops somewhat heavy owing to the long rest, perhaps. Roses of course were cut down to the snow level. All the best Tea Roses stand the winter well, and afford us at least three times the amount of cut blooms that the H.P.'s do. They begin to flower in June, and at this date (Aug. 24) are still crowned with a mass of flowers and buds. In most of the lower lying places shrubs have suffered somewhat from the severe winter, none more so

than the Laurels. Anything in the way of ever greens (tree or shrub) that were newly planted before the severe frosts have almost all perished. Shrub-planting about this part is safest done about October or delayed until spring.—A. DICKSON.

## GARDEN FLORA.

### PLATE 1033.

#### IRIS GERMANICA.

(WITH A COLOURED PLATE OF I. GERMANICA KHARUT.)\*

By the above name the large and comprehensive group of Bearded Irises (*I. barbata*) is generally recognised in our gardens. They are also known under the name of German or Flag Irises; indeed, the commoner kinds are invariably alluded to under the latter name. Of the group as a whole, embracing as it does several well-marked species, together with their numerous varieties, it is impossible to say too much. The ease with which they are managed, their adaptability to all sorts of soils and situations, together with their almost endless variety, commend them to a very large number of those interested in gardening. And not the least of their charms is the indescribable beauty of many of the varieties. Indeed, one of the most extensive growers of these beautiful hardy flowers refers to these Irises as the "Orchids of the flower garden." As a matter of fact, these beautiful and easily grown plants constitute the glory of the hardy plant garden in the early summer, and for a very considerable season contribute a large share of beauty and diversity of colouring of which one seldom tires. Regarded collectively, we find in their blossoms many shades of dark violet and purple, almost every conceivable shade of light and pale blue together with the softest shades of mauve, some exceedingly delicate and almost transparent. Then we have shades of lemon, yellow and golden, together with coppery bronze, and browns in variety, which owe their origin to *I. squalens*, as well as pure whites and primrose, and many more. That any garden worthy the name should be without some at least of these useful flowers is hardly possible, yet I doubt not there are many amateurs and villa gardeners who would gladly grow a few of the more distinct kinds if only space permitted.

Very few hardy plants adapt themselves to so many situations and such varied circumstances as these Flag Irises. They may be arranged in the foreground of shrubberies in large telling groups with advantage and excellent effect if at planting time the shrubs are designedly arranged at wider distances apart than is usual. Such an arrangement will permit of planting large irregular groups in separate masses of colour at intervals throughout the garden, and in positions all too often occupied by the too trim hedge-like outline of a shrubbery bank. In places such as these, proximity to the roots of large trees should be avoided as much as possible. Then again, charming effects may be produced by planting Irises in the wood, especially near to the Grass walks and other openings where they catch the eye. Though seldom seen in such positions, it is surprising how well these Irises succeed on banks and slopes, a fact of which full advantage should be taken, seeing so very few plants are a success in these places.

The kinds that appear best suited to these

\* Drawn for THE GARDEN by H. G. Moon in his garden at St. Albans. Lithographed and printed by Guillaume Severeys.

latter positions are those most closely allied to the germanica type. All of this section grow and flower with as much vigour and freedom as in many prepared borders. Indeed, I have in mind while writing a large railway bank quite near to London which in the latter part of May and onwards in each year is quite gay with the flowers of these Flags. The soil is mainly composed of sand and gravel, and, assisted by the rainfall which drains towards the Irises, they flourish surprisingly. In the herbaceous border of course much will be made of the choicer kinds, while reserving the surplus as well as the more plentiful kinds for the margin of the pond or lake or for wet and marshy spots, in which they appear as much at home as they do in sandy soils. Then again, in convenient positions on the lawn or as forming a belt to other plants, such as Rhododendrons or the like, they make a most agreeable change. Anywhere in fact where space and opportunities permit these accommodating Irises should not be overlooked. In planting such things in the Grass or around the margin of a lake where Grass exists, it will be advisable to loosen the turf somewhat and to remove a portion altogether so as to permit of the due extension of the rhizomes. The soil should also be well loosened to a depth of 12 inches or 18 inches to assist the plants in the start.

In the herbaceous border, or where beds are wholly devoted to the better kinds, the plants well repay for deep digging and a moderately rich soil. In light, loamy or sandy soils they are perhaps most at home, and particularly is this true of the varieties of squalens and variegata. Many kinds grow perfectly on stiff, heavy soils, while the major portion prefer a soil which is neither light nor heavy. In the lighter soils, however, they may be planted or replanted for eight or nine months of the year with impunity, but many kinds will not root afresh in winter-time if planted late in soils that are heavy and cold. While admitting that these Flag Irises may be planted over so lengthened a period with good results, I may be permitted to state emphatically, as a result of experience and observation, that the correct season for planting is the month of April, just prior to the rhizome and its attendant roots pushing forth. I have planted at all times from September to the end of June, but find much the best results from April planting, and give preference to this season for the rarer or more delicate rooters or growers. For example, Victorine and aurea are two kinds finding much favour, but neither is vigorous in constitution, and it is just such as these that need special care and planting at the right time to make them a success. Of course, April planting, if the plants are much divided, means loss of flowers in June, but if it means increased vigour also for the year following, I think there should be no two opinions in the matter. Fortunately, however, the two kinds named are exceptions to the majority in this handsome race of plants.

These few notes would scarcely be complete without some mention of the value of these Flag Irises as cut flowers, and for which they are all beautifully adapted. In fact, during the past few years quite a growing taste has arisen for their flowers, and in season they may be seen in our leading markets in great numbers. For home decoration they are charming, particularly the soft, delicate mauve shades, the pure white, or the bronzes and rich yellows. If required to send to a distance they should be cut while still in the bud, and on being placed in water on arrival at their destination, will gradually unfold their flowers in all their natural freshness and beauty.

The accompanying plate represents one of the true germanica section, Kharput, which is of somewhat recent introduction. It is an excellent kind, equally as early as the type in its flowering. Other early kinds are alba or feren-tina, atropurpurea and Crimson King. The following are some distinct kinds and afford considerable variety: Albicans (syn., Princess of Wales), pure white; L'Innocence, pure white; Darius, yellow; Gracchus, pale yellow; Cordelia, rosy lilac and crimson; Queen of May, full, rose-lilac, fine; Dr. Bernice, bronze and purple; Arnoldi, claret, bronze and rich velvet-purple; Aurea, golden; Mme. Chereau, white, feathered violet, most charming kind; Pallida and Imogene, lovely soft lavender-mauve shades; Spectabilis, deep purple; and Robert Burns, golden and velvety maroon. E. J.

## THE WEEK'S WORK.

### HARDY FRUITS.

**GATHERING FRUIT.**—The most important work at this season is storing and gathering the fruit. In the case of large or soft fruit great care is required in handling. Those who have a good knowledge of varieties know the value of leaving the later kinds till the fruit is thoroughly matured to prevent shrivelling and decay. In no case do I advise premature gathering, but with the season so far advanced it is not advisable to allow soft fruit, such as Warner's King or Lord Suffield, to suffer by ripening on the trees or to drop. Apples with a tender skin may be gone over more frequently, the ripest being stored, first securing large specimens. Those who thinned their fruit a few months ago will now reap the benefit. In placing large fruit in baskets it should not be heaped up, but laid in a single layer with a soft material to rest upon, such as fine hay or dried grass; the latter I like best, being softer. Care should also be taken that the fruit does not press against the sides of the basket. Many of the Apples are this season ripening earlier than usual, and even in late districts there should be no delay in securing what is left of the crop of what may be termed early cooking kinds, such as Hawthornden, Lord Suffield, and Warner's King. The same remarks apply to Pears. With these there is more decay than usual, and wasps are troublesome. Such kinds as Pitmaston Duchess, Marie Louise, and Margaret Marillat are earlier than usual and need to be stored to save the crop, as though protection may be afforded from birds, it is difficult to keep wasps from large pyramid or bush trees. Pears decay so soon that the seasons given for these fruits cannot be relied upon. The cultivator will do well to store in a cool place, relying upon different rooms if possible for late kinds which require less attention, and if space is not available give keeping kinds the coolest and darkest place; indeed many varieties keep well stored in boxes in layers if placed in a cool, dry place. It can readily be seen if the fruit comes from the trees without force, and a true test as to fitness is when the pips are well browned and quite firm. The fruit should be gathered when quite dry, and any speckled or grub-eaten samples should be kept clear of fruit stored for future use.

**STORING FRUIT.**—Of late years the belief has sprung up that an elaborate store is necessary, whereas the reverse is the case. By this remark I do not mean to convey that rough and ready treatment will conduce to long keeping, but that many shifts can be made to store when there is a glut of fruit. A cool room with a thatched roof will be better than a warm heated place with daily fluctuations of temperature. Again, dry cellars make a good store. I always kept my late Pears best in a dry disused ice well, and many kinds of Apples, such as Northern Greening, Striped Beaufin, and Minchal Crab were stored in thick layers on floors in a similar building. Only

those kinds with hard flesh can be stored thus. I have found an airy warm room the worst place to keep Apples, and in no case should the fruits come into contact with straw or hay, no such covering being necessary over shelves or on floors if the fruit is a long-keeping kind. Free ventilation is necessary for early fruits, but draughts should be avoided. I prefer a dark room with sufficient air or ventilation to let the moisture and gases escape. Cleanliness is important, and for late Apples barrels lined with clean paper to exclude air or draughts may be used if the fruits are packed in carefully.

**LATE PLUMS.**—Fruits of late kinds as they ripen should be placed in tissue paper and be laid in shallow boxes or drawers; treated thus they will keep good for weeks and do not lose flavour. For late dessert use Coe's Golden Drop is one of the very best keepers if placed in single layers as advised above, each fruit being twisted in soft paper. Such varieties as Belle de Septembre, Monarch, and Wyedale will keep a long time in a cool place; indeed some seasons I have kept Wyedale well into December. This kind should find a place in all gardens. Damsons are very plentiful, but soon decay if placed in thick layers. To preserve late fruits it is well to place thinly on floors in a cold store, and in gathering take those on the sunny side first. The Cheshire or Shropshire Prune is a fine late variety, and should be gathered last, being an excellent keeper.

**SELECTING NEW FRUIT TREES.**—Now is a suitable time to select new trees. No matter how well a garden is managed there is a certain amount of planting every year. If the trees be planted early there are very few losses by severe weather or by drought in the growing season. By selecting a certain number of trees yearly these can be prepared by growing them one year at home. They may be purchased either as maidens or after one season's growth from the graft. These remarks apply more especially to stone fruits, as by growing as advised they may be lifted the following season much earlier than when first purchased from a nursery. Only those kinds which thrive in the locality should be grown. Any new varieties should be grown sparingly for a time. Quality should be the first consideration in a private garden, not mere size. If both, however, can be secured, so much the better, as appearance goes a long way. Any small bush fruits required should likewise be secured. There is always a demand for these trees very early in the season, and if obtained late the plants are not always so good as one could desire. Gooseberries and Currants are often seen covered with fungus; whereas new trees would give much finer fruits and in quantity. In purchasing these trees always select those with a single stem, as there is less trouble with sucker growths and the fruit is more readily gathered.

**RASPBERRIES.**—Plantations that have been long in one place should be renewed, and in case the canes are much exhausted, it is well to purchase new stock. At this season old quarters need attention in the way of final thinning and removal of useless wood, only leaving what may be termed the bearing wood for next season. From four to six new growths are ample for a stool, leaving the smaller number if the shoots are strong. In many cases it will be found the best canes are at some distance from the old stools, having pushed out in search of new soil and room to develop. These must be retained if there is ample space for them to grow. I am aware stools wide apart look unsightly, and when they get out too far it is well to replant. Raspberries are often allowed to remain too long in one place, change of soil and position being beneficial. In replanting, trench the land and manure freely with decayed animal manure, plant firmly and give plenty of room. Now is a good time to feed plants which have borne freely, unless a good mulch was given earlier. Liquid manure may be given the plants now, as the food will assist in making good fruiting wood for next season.

**STRAWBERRIES.**—The beds recently cleared of runners should now receive attention as early

as possible if required to fruit next season. Plants that have borne a crop will well repay liberal feeding. No time should be lost in cleaning, cutting away any weak runner growths and old leaves, and making the quarters neat for the winter by lightly hoeing between the plants and raking away rubbish. Now is a good time to feed liberally, as the stronger the crowns are, the better will be next season's crop. By manuring now time is saved in the spring, the plants then only requiring some litter to protect the fruits. Young plants if not strong do well placed in a sheltered corner in lines, and transplanted with a ball early in the spring. Plants in pots for spring planting should be plunged in soil or ashes well over the rims of the pots to protect from frost.

G. WYTHES.

#### KITCHEN GARDEN.

**LEEKs.**—These continue to make growth over a long period; therefore feeding where the plants have exhausted the manure which was dug into the trenches may be carried on with a liberal hand. In a dry season like the present liquid manure is not always procurable in sufficient quantities to meet the demand of large kitchen gardens, but a good substitute may be found in fish manure sprinkled freely in the trenches and well washed down to the roots by artificial means. The earliest planted lots, if wanted for use in November or for exhibition, and which received a partial earthing up three weeks or a month ago, may now, after being thoroughly well soaked, receive the final lot of soil. Water the afternoon previous to earthing. Some growers recommend shortening the main leaves somewhat, thinking that thereby more strength is thrown into the stems and heavier roots are obtained. With the exception, however, of reducing their length when transplanting them in the spring, I never practise it, as I think little, if anything, is gained by the practice. Main crop lots not needed for use until December and January may be allowed to grow away for another fortnight before any soil is placed round them, as this process doubtless has a tendency to check growth, and Leeks being very hardy there is no fear of injury from early frosts even though unearthed, as in the case of Celery, which soon suffers if frozen through when in a wet state. The same liberal system of feeding these successional beds of Leeks should be practised for some time yet, as the ground in most gardens is in a dry state in spite of the showers which have fallen of late. Plants growing on the level ground, and which are intended for use in soups and ordinary kitchen work in order to save the more important supplies, should have the soil between the rows stirred occasionally, and always immediately before water is applied, as the loosened soil keeps the water from running in channels and the roots of each individual Leek get their full share of moisture.

**TRIFOLI ONIONS.**—The second sowing of autumn Onions intended to follow those sown at the commencement of August will now need attention. First of all let the seedlings be freely thinned out, making of course an allowance for a probable attack of the Onion maggot, which on hot soils is more troublesome this autumn than usual, owing to an insufficiency of root moisture and a somewhat tardy growth. After hand-weeding and putting the Dutch hoe through the rows, apply a liberal surface-dressing of guano and soot, watering freely afterwards. I have seen good results from an autumn mulch of leaf-mould or old Mushroom manure on sandy porous soils, this not only conserving the moisture, but if sufficiently thick, protecting the bulbs from injury by frost during winter. It also prevents them from swaying to and fro, as they are apt to do in exposed situations in windy weather. After removing the surplus plants, make the remainder firm by pressure from the finger and thumb. Late-sown crops of Spanish Onions are this year much affected by mildew in low-lying situations; therefore extra care is needed in harvesting the bulbs. Remove

them at once if possible to any airy open shed, or, better still, a cool glass house, where they can be frequently turned. If left out in the open garden, mildew and probably a second growth will make great headway.

**SORTING POTATOES.**—In most gardens where Potatoes as they ripen are lifted they are placed in open sheds with a view to their being overhauled on wet days. As, however, wet days are less frequent this season than usual, it will not be wise to neglect sorting for any length of time, as when the tubers lie thickly together and the weather is very warm, overheating engenders a second growth and encourages disease to spread amongst any sorts which may already have become affected. All tubers, whether intended for eating or seed, are much better for being stored in a cool place where abundance of fresh air can reach them. For this reason a north aspect is preferable to any other, a more equal temperature being there preserved, and diseased tubers should be burnt or buried deeply, not given to pigs, as it is stated by acknowledged authorities that manure from piggeries where diseased tubers have been used for feeding, if dug into land intended to be cropped with Potatoes, will induce disease: hence the necessity for care in this matter. The eating portion of the tubers will be better for a covering of dry Oat straw or Bracken, in order to prevent them turning green. Earlier lifted lots must not be forgotten, but examined occasionally for the removal of any odd diseased tubers, the turning itself doing them good by allowing the air to circulate amongst them. Where price is an object, it will be wise on the part of all those who need seed of any new variety to purchase in autumn, instead of waiting till spring, as then the price of good seed is invariably raised. If such sorts as Ringleader, Sharpe's Victor, or any of the first early sorts should emit sprouts, remove them at once, or much of the vitality of the tubers will be drawn out.

**BROWN COS LETTUCE.**—The plants of this good old hardy Lettuce from early August sowings will now be coming on apace, and will, with liberal thinnings and waterings, make strong plants for pricking out under the shade of south and west walls from the first to the third week in October. With this operation in view, the ground should be got in readiness for the young plants, several soakings assisting to consolidate it by that time. If the soil is in fairly good heart, old Mushroom manure forked in in fair quantities will grow Lettuces well, such material producing a growth calculated to stand the winter better than that resulting from the free use of rotten farmyard manure, and feeding in spring can always be resorted to. After turning up the soil to the required depth and incorporating the manure, it should first be well moistened, then well firmed, this being repeated in the course of four or five days.

**LATEST DWARF PEAS.**—Care will now be needed in the case of any rows of Chelsea Gem, William Hurst, or English Wonder, sown for supplying a few dishes after such tall sorts as Ne Plus Ultra are past yielding. The same syringing as advised for these taller sorts a few weeks ago will be necessary with the dwarfs if mildew is to be kept at bay, and as the pods have just well formed, encouragement must be given to the swelling Peas by administering a copious watering once in ten days over a good mulch of rich manure; support the haulm with neat sticks, and thin out if found to be still too thick. Owing to the protracted September drought, Scarlet Runner Beans will still need root moisture where yielding freely.

J. CRAWFORD.

**Violets from cuttings.**—When inspecting the stock of Marie Louise Violets at Blickling recently I was much struck with the single crown character of the plant, duplicates being the exception. On questioning Mr. Ocle, however, he informed me that the plants were raised from cuttings instead of runners, as is most commonly practised, and that finer blooms are the result. I

have heard of Violet growers reducing the crowns by the aid of a sharp knife after the plants from layers were in active growth, but I have never practised it myself, although as a rule I gather better blooms from plants with say three or four crowns and a moderate amount of foliage than from thick bushy ones, and it goes without saying that damping in winter is more easily combated. I knew one good grower who always selected as many of his runners as possible from plants having few crowns, no doubt thinking, as Mr. Ocle does, that the fewer crowns and less foliage the better. —J. C.

## FLOWER GARDEN.

### AMERICAN IRISES.

AMERICAN Irises do not seem to have received the attention from cultivators that they deserve. It is doubtful if there be at this time a complete collection even of the different species in any one garden, while there are no doubt good varieties which have never been cultivated, and probably not even collected for herbariums. Again, there are varieties which have only a local reputation, and which have not been generally distributed. I have found a number of varieties of this kind; some of these have not yet flowered here. Some of our Irises are most difficult to establish, and it will task the skill of an eastern grower to flower some of the west coast species, which resent removal and naturally are at rest during our summer season. We have a trio of beautiful dwarf Irises in *I. cristata*, *I. lacustris* and *I. verna*, of which the first two belong to the crested section, or *Evansia* of the botanist. Of these

*I. CRISTATA* (*I. odorata*, Pers.) is the prettiest and usually most amenable to cultivation. It increases rapidly if the short creeping rhizomes are planted in moist, light rich earth; though, on the contrary, it will grow vigorously on a rockery, where, however, it is likely to be injured during a hard winter. When covered in the spring with its light mauve-coloured flowers nothing could be prettier.

*I. LACUSTRIS* has the habit of *I. cristata*, and purple flowers with a yellow crest. It grows on the shores of the great lakes, where it is very plentiful. It thrives under cultivation in a moist soil, but is rather shy in showing its flowers.

*I. VERNA* is a member of the sub-genus *Pardanthopsis*, of which there are only four species, the others being very rare. It has short, creeping root-stalks, narrow, taller leaves and no crest; its flowers are dark rich purple, with yellow markings. It is a plant not uniformly happy in gardens, but not a difficult subject. Everyone knows the common Flag of our Eastern States,

*I. VERSICOLOR* (*I. picta* and *I. sativa*, Miller), a plant which thrives equally well in brackish, marshy, fresh-water swamps, or perfectly dry ground, and may be depended upon to hold its own under very adverse conditions. I have never seen any variations from the type, but Baker notes varieties *I. virginica* (*I. caurina*, Herb.) and *I. placida* (Spach.) as forms with some distinctions of structure and colouring. I have also noticed in foreign catalogues other names, as *I. versicolor* Kramer. It seems to me useful to note synonyms as warnings against accumulation of plants whose names in catalogues are often so many traps for the unwary. Some dealers even offer the same plants under different names at different prices. Our other common Iris, which is often nearly as thickly sown as Grass in a meadow, is

*I. PRISMATICA* (*I. virginica*, Gray; *I. gracilis*, Bigelow; *I. Boltoniana*, B. and S.). With its narrow leaves, a foot or more high, and purple flowers, this is a species which is graceful in habit and effect. Allied to *I. versicolor*, though a separate species and a distinct garden plant, is

**I. CAROLINIANA**, which was discovered a few years since by W. A. Manda in North Carolina. This has somewhat flexuous leaves, very slightly glaucous, brownish spathe valves and light lavender flowers of fine form. Further south, on the Atlantic coast, is found another beardless Iris,

**I. TRIPETALA** (or *I. tridentata* of Pursh). This is interesting to the botanist, as having smaller standards than any of the narrow-leaved kinds of this section (Apogon). It is an attractive dwarf-growing purple Iris, flowering late in the season. While it is hardy here, it does not seem quite satisfied with our winter climate. After worrying most of the collectors on the coast, I succeeded in securing this from Florida. It is a plant in request among Iris fanciers, and scarcely to be had: we from the dealers, who confound it with *I. Hookeri* (or *I. tripetala* and *I. tridentata* of Hooker), which is a Canadian Iris with the habit of *I. versicolor*. Another southern Iris is

**I. FULVA** (or *I. cuprea*), with flowers distinct in colour from any other species of the family, and of a spreading Merea-like form when open. The form usually in cultivation has flowers of a rather dull coppery brown, but lately *Meehan's Monthly* figured, in a coloured plate, a form with brighter coloration in pinks and browns, so that there are evidently variations of this plant to be found. Beyond the Mississippi to the Rockies we seem to have only one species,

**I. HEXAGONA**, though this is found also in the Southern States as far east as Florida. *I. hexagona* makes wonderful rhizomes, nearly round, 1½ inches in diameter and sometimes 2 feet long. Naturally it requires good lateral root room and good supplies of moisture. No Iris has given me greater pleasure this year than *I. hexagona* var. *La Mance*, which was discovered last season in Benton County, Arkansas, and has been named in honour of Mrs. L. S. La Mance, the discoverer. This is much superior to the type, and has slightly pendulous leaves 1 inch or more wide and 2 feet high. The stems are spreading, leafy, and bear several two to three-flowered spathes. The flowers are large, with standards and falls both spreading and of a rich blue-purple, shading to white. The styles are light green. The plant in flower is very distinct in habit and most effective and striking. Besides the type, I have also an unflowered variety with flowers of a lighter hue. A friend in Florida has sent me a native form of *I. hexagona* with white flowers. This rarity should be a great gain, white Irises being the quintessence of floral beauty. Westward, again, there is said by Coulter to be only one species in the Rocky Mountain basin,

**I. MISSOURIENSIS** (*I. Tolmieana*).—This is a narrow-leaved kind, with light purple flowers, the falls of which are reticulated. The flowers are small, but it is a vigorous species and rather attractive. Westward again we find a number of species and varieties, which, from a gardening point of view, form an interesting group. The list comprises *I. tenax*, *I. tenuis*, *I. macrosiphon* and varieties, *I. Hartwegi*, *I. Douglasiana* and varieties (*I. Beecheyana*, *I. Santa Cruz*, &c.), *I. bracteata*, *I. longipetala* and varieties.

**I. TENAX**, a linear-leaved species from Oregon and northward, offers no difficulty in cultivation here and flowers regularly, without special attention, early in the season. Its rather small light purple flowers are attractive.

**I. TENUIS** I have not been able to secure, and shall be glad if some reader in Oregon would favour me with seed. Judging by its habit, it is probably a plant difficult to establish.

**I. MACROSIPHON** is said to be very handsome and free-flowered, ranging in colour from yellow through the whites and purples. Mr. Purdy has transplanted this successfully to his garden on the Coast Range, but, of course, his climate is not an eastern one, and the plants rest and grow under somewhat normal conditions. Herr Max Leichtlin has lately re-introduced *I. macrosiphon* to cultivation from seed, and we are likely to hear more of it.

**I. HARTWEGI** was first specially brought to my notice a few years ago by an English friend, who is one of the best of amateur gardeners. He had once had it established, but had lost it, much to his regret. There may be others outside of California who have established it, but probably not many. The friend who sent me some plants this spring says: "Remember that they require a dry locality. They never drink a drop of rain from the middle of May till the end of September at the earliest, and they are to be found only on those hillsides where they are drained to perfection; never near a moist or wet spot. I do not recollect having found them on any but dry slopes, and there strong in the sun, and slim and thin if shaded too thickly by Pines, *Pinus ponderosa*." Strong roots and thin roots have mostly gone quickly to the majority in my garden, though at present there are some survivors under cover and dormant, besides seedlings. It will be seen that such plants are likely to cause a gardener some trouble. If we are to grow some of the Californian and many of the Asiatic plants, it will be necessary to arrange a summer drought for parts of the garden. There is also another little matter which bethers a gardener in growing some of the early-flowering plants—our seasons are sometimes so late that the plants do not move until their natural flowering season is over, and this is apparently prejudicial to their perfection.

**I. DOUGLASSIANA** has several varieties, and Mr. Purdy informs me that he has seen some beautiful natural hybrids with some other species. Of these and *I. bracteata* I have had little experience beyond losing them one or more times.

**I. LONGIPETALA** is a species which seemingly requires no special treatment, and has grown here for some years with so little attention that I do not at the moment remember the distinguishing features of its purple flowers.

These notes, which perhaps give a large proportion of negative information, are offered in the hope that observers of our native flora may be induced to notice and collect Irises which may differ from the types, and favour us with notes on the natural habitats of some of the little-known species.—J. N. GERARD, in *Garden and Forest*.

#### NOTES ON HARDY PLANTS.

**Dryas lanata**.—It is certainly hard to distinguish this kind from the common octopetala when not in flower, but in the latter state it is just as true that the most cursory observer would know it as a much finer variety as regards the flowers. Moreover, it has the habit (in the case of strong specimens) of flowering freely in the autumn, and the fact of a fine show of bloom at present has suggested this note.

**Linaria hepaticæfolia**.—This is a pretty little plant with many capabilities. This plant is an instance of that "little and often" care needed by which, and which alone, our rockeries can be kept orderly. I have seen this pretty creeper in one season kill all around it for the space of a yard. This is not the plant's fault, but the gardener's, for we have none too many of its class—creepers with the dense habit close to the surface of the ground.

**Silene quadrifida var. pusilla**.—Nothing has been, and scarcely could have been, more lovely than this humble plant all the present summer. It began in June to produce its myriads of flowers, and they are opening yet. It may be described as a pigmy *S. alpestris*, with the elegance that its divaricate hair-like stems may be imagined to impart. The whole plant does not exceed 4 inches in height when in bloom, and the flowers are of the purest white, a quarter of an inch to half an inch across, with the quadrifid feature constant. Culturally, it is neither a miffy thing nor one that runs away smothering other things and coming up where not wished, as some of its genus do. Given a light soil, sandy, and with a few bits of chalk added, it will stand for

years in one place healthy and happy. Certainly it is one of the best and most winsome of alpine as a decorative plant.

**Rosa Wichuria, or Wichuriana**.—At the present time this is a Rose bush to linger over, and yet it is scarcely a bush because of the peculiar habit of disposing its long stems flat on the ground: these are densely clothed with small shining foliage, among which nestle short branchlets of flowers, resembling the white Japanese Anemone close by. For a big rockery it must be a glorious subject. Its hardiness is beyond all doubt. I have grown it three years, and, as I take it, last winter would be a fair test. It then stood on the top of a bit of rockwork simply protected by a few Holly bushes on the north side. It is practically evergreen, which is no mean feature for a Rose employed as indicated.

**Primula Forbesi**.—Flowering freely as it is now doing in the open air, it is worthy of note: besides, the flowers are numerous and bright, in the way of our native *P. farinosa*, though the foliage is quite different from that species. It is reputed to be tender. I have not tried it yet, but some of my plants will be available for trial in a favourable corner. It is because the plant is such a pronounced gem and very free-flowering in summer out of doors, that, hardy or not hardy, it is worthy of the extra care of lifting it in the autumn. J. WOOD.

Woorville, Kirkstall.

#### TUFTED PANSIES.

ANYONE contemplating employing these for the flower garden next season should now secure stock. Nurserymen who make a speciality of them put in cuttings in July and August. These if placed in a sandy soil in cold frames make very useful plants for placing out in beds or borders for spring and early summer bloom, or one and two-year-old plants may be lifted, divided and planted out in a nursery bed for transplanting in December or January, though these months are fully late because of the danger of disturbance by frost. To furnish a glorious feast of bloom in spring and early summer there is nothing like plants put out in the spring of one year and allowed to stand through the winter to bloom the spring and summer following. Such plants are helped by a good top-dressing of some rich soil in autumn, and as they are thoroughly established and have rooted deeply, they make large tufts and bloom grandly. I had such a plantation this season, and in spite of the severe drought the plants stood the strain bravely, greatly helped by a layer of cow manure a foot below the surface. It is astonishing how strong plants will send down roots deeply into the soil in search of such nutriment. A dozen of most useful varieties will be found in William Niel, a delicate rosy pink variety which has been most persistent in flowering all the season, no matter what the weather has been; Ardwell Gem, still one of the best yellows; Goldfinch, Duchess of Fife, Christiana, a fine white; Blue Gem, Lemon Queen, Countess of Hopetoun, Border Witch, J. B. Riding, for its peculiar reddish tint; Rosea pallida and Blush Queen. By way of making a baker's dozen add Sylvia, white, one of the Violetta section. I may also mention a few of the best new and old kinds I have seen this season in their different sections. I can name, of blotched and shaded flowers, Iona, a beautiful flower, which really marks an epoch, the lower petals being blue-black, each having a white blotch at the edge, the upper petals lavender; Craigie, purplish crimson and delicate lavender; Princess Beatrice and Cottage Maid. Of edged flowers, Duchess of Fife, which has a distinct edging of blue on a primrose ground; Border Witch, delicate soft blue, finely shaded (these two are quite at the head of the section); and Amazon, a variety which finds a great many admirers on account of its broad orange-amber belting to a white centre. The best whites are Countess of Hopetoun, one of the best and most useful still; Christiana, and Sylvia. As a purple

self, Archie Grant heads the section, and as a blue, Blue Gown. The finest yellow is undoubtedly A. J. Rowberry, but being new and likely to be scarce for a year or two, it will be high priced for a time; it has an excellent habit and is very deep in colour. Add to these Lemon Queen, George Lord, deep primrose, W. Niel, *Rosea pallida*, and Blush Queen, blush.

Now is a good time to sow a little newly-gathered ripe seed, taking a box, filling it with a good free soil, scattering the seeds thinly over the surface, adding a slight covering of a fine sandy compost, placing the box in a cold frame, and protecting from heavy rain. By keeping the seedlings in the seed-box all the winter, and planting out in well-prepared ground early in March, such plants will get into fine bloom in May and June, and the raiser will experience a pleasant sensation day by day in watching the seedlings unfold their blossoms. R. D.

**Cactus Dahlias.**—The monster blooms of these we see at exhibitions may be all very well, but for house decoration one cannot do anything with them where tasteful arrangements are required. The flowers of such sorts as Black Prince, Cannell's Favourite, and several others are much too large. In my opinion it will be better for the raisers of these Dahlias to discontinue doing so altogether, because there is always a tendency for the newer kinds to take the place of older ones, and for the garden and the house we shall be better off with what we have than to increase the number of varieties that have only size to recommend them.—J. C. CLARKE.

**Carnations from seed.**—Much of late has been written in THE GARDEN on Carnations, and one or two notes have appeared on raising them from seed. Having tried several packets of seed during the last few years, I should like to point out that this way has many advantages in a situation where it is very difficult to get on with Carnations. For several years I obtained plants from the best sources, using every effort to keep up a stock, but in vain. Some kinds positively refuse to grow at all, Mrs. R. Hole and Ketton Rose being examples. Some years ago I began growing Carnations from seed, and although I cannot keep them clean long, they go on much longer than plants raised from layers. No doubt this arises from the seedlings being more vigorous and better able to ward off the spot. In January, 1893, the president of the Carnation Society sent me a packet of seed of his own saving. I sowed it in March in a box in a frame, and when strong enough the seedlings were pricked out in an open raised border, so that I could place a frame over them to keep off the heavy rains. In this position they wintered grandly. In March these were planted out on a raised border in full sun, where they grew away splendidly, giving us a grand lot of blooms for three months. From this packet of seed many of the flowers surpassed those of kinds sent out under name. As I planted them somewhat thickly, the single kinds were removed as the

flowers opened. I have now layered many of the best growths: some I have layered into pots, intending to keep them in a cold house on a shelf through the winter.—JOHN CROOK.

#### PANCRATIUM ILLYRICUM.

THIS truly lovely species is, strictly speaking, the only member of this noble genus sufficiently hardy to endure our winters in the open ground, and that without protection. And seeing this is the case, it is all the more surprising that so good and choice a subject should be so seldom seen among collections of hardy plants. Even in those gardens where hardy bulbous plants for the most part find a congenial home the above plant is rarely seen, and yet there are few gardens that could not provide a suitable home for it. As may readily be seen by a glance at the charming group in the accompanying illustration, this hardy kind possesses flowers of as equal purity and chaste-

good condition it will assuredly fix itself on the memory. In bulbs of flowering size the foliage on first emerging from the earth is for some time erect, but with the uprising flower stem the leaves often assume an angle of 45° or thereabouts, with the lower ones often quite flat on the soil. In this stage the aspect of the plant is of the most distinct kind. It is an excellent plant for the cool conservatory or the winter garden or such like places. Notwithstanding its complete hardiness, the purity of its flowers is best preserved when given glass protection. The plant usually flowers about midsummer, the flower-spikes attaining to about 18 inches high, each umbel containing from six to a dozen of its large white, fragrant, and handsome blossoms. Large bulbs frequently produce two spikes each, and these give a supply of blossoms for some considerable time.

#### CULTURE.

When grown in the open ground, a position at the base of a west or south-west wall should

*Pancratium illyricum* in Corsica. From a photograph sent by Mrs. Robb.

ness as the more tropical species. This fact alone should tend to make it at once popular with all who desire to possess rare or beautiful flowers, and who have not the requisite heat at command to grow those species for which high temperatures are essential. This beautiful plant is a native of Southern Europe and one of the most distinct of its genus, a fact fully demonstrated in the illustration, which displays its high decorative value in a charmingly natural manner. The broad, ligulate, and distinctly veined leaves closely overlying each other, as well as their generally sturdy and vigorous constitution, are unmistakable characteristics of this species, and when once seen in

be given it. In such a position it would be quite an easy matter to make a narrow border into a special home for this and similar things. For example, this *Pancratium*, together with the *Belladonna* Lilies and some of the hardy *Crinums*, such as *C. Powellii* and *C. longifolium*, all summer-flowering plants for which a similar treatment would suffice, may be brought together, and thus constitute a most pleasing group. One of the most important items is free drainage. This is best secured by removing the original soil fully 2½ feet deep and placing 6 inches of brickbats in the bottom of the border. The soil best suited for this bulb is loam, peat, rather rough leaf-soil and a

liberal addition of sand. A soil that is of a clayey nature should be avoided altogether. When preparing the bed, a good layer of cow manure or well-rotted hotbed manure may be placed in the trench at 15 inches deep, or it may be stirred into the trench with the soil at 12 inches deep. The *Pancretrium* should be planted fully 6 inches or 8 inches deep; the other bulbs named must be planted more deeply, 9 inches to 12 inches at least. The early autumn months are the best for planting, and once well done they may remain for several years; indeed, the great secret of success when well planted is in letting them alone. Unless the surface of the bed is carpeted with evergreen plants, a covering of short litter or cocoa fibre 6 inches thick or a good mulch of short manure may be given by way of making them more secure. With such a covering, however, *Pancretrium maritimum* may be added as a good companion to those already named. With frame culture the latter retains its foliage, while *P. illyricum* is deciduous.

These *Pancretriums*, while somewhat slow in producing offsets, may be raised from seeds comparatively easily, the seedlings attaining to flowering size in from three to five years. In this way a good stock of this handsome hardy bulb may soon be obtained. E. J.

**LILIUM SPECIOSUM AND ITS VARIETIES.**

I must thank "Delta" (p. 205) for directing attention to the white variety *Vestal*, which is at present very little known. Concerning *Melpomene*, reputed to be of American origin, there is no doubt that the form now grown under that name is quite distinct from the transatlantic variety which was raised by the late Mr. Hovey, of Boston, and reported to be a hybrid between *L. speciosum* and *L. auratum*. Mr. Hovey himself sent me a bulb in, I think, 1880, but neither in foliage, flower nor bulb could I detect any trace of *L. auratum*, and the Lily in question turned out to be a good large-flowered form of *rubrum*, certainly not so dark as the *Melpomene* of the present day. There are some beautiful well-marked forms to be found among the coloured varieties sent to this country from Japan either under the name of *rubrum* or that of *Melpomene*. Some of these latter are very richly tinted; indeed, there is a good deal of individual differences to be found among them. Out of a number of imported bulbs that I have flowered this season, the greater part consists of the richly-coloured *Melpomene* and the strong-growing form with somewhat lighter coloured flowers known usually as *rubrum superbum*, but other kinds have cropped up, though only to a limited extent. Two in particular have attracted notice, the first being the very finest of the *roseum* section. A suggestion has been made and is now generally acted upon to classify all those with green stems and flower-stalks under the name of *roseum*, and to regard as *rubrum* those in which the stems are brown or of a reddish tint. That just referred to as the finest of the *roseum* section has all the characteristics of *roseum*, but the flower is far more beautiful than any of the Dutch forms. The blossoms of this are large and the segments reflex in a symmetrical manner, thus forming a grand bloom. The interior of the flower is of a rosy tint disposed in a more regular manner than is usually to be found in those bearing the name of *roseum*, while it is also particularly remarkable as being with one exception the last of the *speciosum* group to unfold its blossoms, being in fact later than *Melpomene*. The exception just referred to is quite a distinct variety, and must be awarded the palm as the latest of all the *L. speciosum*. In this the stem is more or less tinted with chocolate, particularly on the upper part, while the foliage on the lower portion of the stem is narrower than in some of the others, distinctly channelled, sharp-pointed and dark green. On the upper part of the plant, however, the leaves are broader. The flowers are supported on pedicels pushed out almost hori-

zontally from the main stem, a distinctive feature by which when in bud this Lily can be selected from any of the others. The blooms are not particularly large, but of a good shape and deeply coloured, certainly not so dark as those of *Melpomene*, but, like that, with a white margin to the petals. These two last-mentioned varieties are, from the lateness of their flowering, very useful Lilies.

As soon as the flower-stems lengthen and the leaves develop, they can be readily selected from the others. Of these two kinds, however, as a rule, only a few make their appearance among the importations of *rubrum*. Of white varieties, "Delta" does not mention *album novum*, a variety which sometimes crops up among the bulbs of *Kraetzeri*, from which it differs slightly in the foliage, but more so in the flowers, which are somewhat larger and more massive than those of *Kraetzeri* and not quite so regular in outline. A prominent point of difference is to be found in the anthers, which in *Kraetzeri* are chocolate-brown, and in *album novum* clear yellow. H. P.

**FLOWER GARDEN NOTES.**

**FRAMES** that have been occupied by layers of Tree or perpetual-flowering Carnations now potted up or by Pinks that are planted out can at once be utilised for other things. East Lothian Stocks sown in boxes in August will soon be ready to handle, and may be pricked out into these frames 3 inches apart each way. The compost prepared for Pinks and Carnations will do very well for them. Late summer-sown Stocks come so early into flower the following year, are so useful for cutting, and make such a fine display right through the season, as to fully merit any attention bestowed on them. In similar quarters may also be inserted cuttings of *Antirrhinums*, *Pentstemons* and *Phloxes*, either in the ground or in boxes, as may be deemed advisable.

**LATE FLOWERS.**—It is not often that one gets such a capital second display on the *Phloxes*, but after partially taking out the first central flower-spike there was a heavy downpour of rain that thoroughly set the plants on the move again, the development of back spikes and lower growths was rapid, and the season has been at once continuous and well sustained. This practice of prolonging the season by the removal of the first flower-spike, even if necessary at the expense of the flowers, is always advisable in the case of many herbaceous plants, especially where they occupy prominent positions, and it is necessary to carry on the display until the end of the season. One does not always care to sacrifice, we will say, a fine spike of scarlet *Lobelia*, but when by so doing half a score of smaller spikes are quickly developed, the sacrifice is hardly regretted. The result of a proceeding of a somewhat similar nature may also be carried out at the present time in the case of the dwarf clumps of *Chrysanthemum uliginosum*. On the ordinary border plants flowering well at 4 feet are much more serviceable than if they were nearly twice the height, and the sturdy habit prevents the necessity of staking or tying. This *Chrysanthemum* and also such white-flowering *Starworts* as *Aster ptarmicoides*, *Harpur-Crewe* and *Purity* (especially the last-named) will be found very valuable at this season if white flowers are wanted in quantity for harvest festivals or home decoration. If long branches bearing their large spikes of flowers are cut in various lengths and placed in pots of damp soil, they will mix well with almost any kind of foliage, and the special value of the *Starworts* lies in the fact that whilst the long branches can be used for bold grouping, all the side shoots will come in for smaller work such as in window-sills, choir stalls, &c. Apropos of the question of foliage for such work, I may mention that if the supply of house plants is somewhat scanty, substitutes can be found in long shoots of the *Bamboos*, also of the tall *Water Reed* and the *Bulrush*.

**HERBACEOUS BORDERS.**—The quantity of flowers furnished by *Starworts* and perennial *Sunflowers*, to which may be added the late display of *Phloxes*,

is answerable for the fact that September is about the best month on the herbaceous borders, so far, at any rate, as the larger plants are concerned. Note should be taken of the display as a whole at this season to see if any alterations would be advisable—that is, in the different arrangement of clumps to give at once a good variety throughout the borders and a general harmony in the colours. So far as the *Starworts* are concerned, a mistake is not easily made in the blending or contrast of colour. The chief point is to see that the several varieties are well distributed. Again, another point is to note the behaviour of some of the less known and higher class things with the view to change their quarters if the progress has not been satisfactory. It is not altogether that these are superior as border flowers to the best varieties of well-known species, but considerable notice is taken of them, either because their flowers are unique among hardy plants, or there is something in their constitution which renders their cultivation a subject of interest to the plant-lover. *Gentiana acaulis*, *Heuchera sanguinea*, *Dracocephalum grandiflorum* are cases in point. In connection with some things it may be noted that recommendations as to the most serviceable site must not be taken too literally. A dry sunny border, for instance, should not indicate one that is apt to get thoroughly parched up, and whose dry nature is partly attributable to the fact that great clumps of the most rambling and hungry of herbaceous plants have been located there for many years and drawn all the goodness from the border. There are comparatively few among herbaceous plants that do not like a bit of good soil, although other requirements may include a sunny spot and good drainage.

**DAFFODILS.**—The planting of these, whether in small clumps on borders or on a large scale in pleasure grounds, should be pushed forward and completed as soon as possible if not already done. In the short list of good *Daffodils* to be planted in small quantities on borders I omitted to mention the *Gardenia*-flowered *poeticus*, a cheap and at the same time a very useful variety. The different forms of *poeticus*, both single and double, have a preference for a rather stiff soil—at least I found they did not take kindly to the sandy sub-soil in which they were first planted, so they were lifted three years ago and transferred to the front part of a *Vine border*, where for the last two seasons they have given a lot of flower. If there is a batch of *obvallaris* in some warm corner, it will be well to put on a mulching of leaves before the approach of frost; the natural flowering season will be considerably advanced thereby, given an early spell of sharp weather and a break up of the frost in January with little very sharp frost after that date.

**PRESENT WORK.**—Certain work in the flower garden must not be neglected because of the expectation of early frost; we may have the glass so low towards the latter end of the month as to make a clean sweep of most of the flowers, but, on the other hand, sometimes frost is delayed until the end of October, and, with the hope of being thus favourably treated, the removal of seed-pods and dying flowers from *Sweet Peas*, perennial and annual *Sunflowers*, *Calendulas*, *Gaillardias*, and other things may still continue, and all back flower buds now showing will be developed if there is no frost. If a good batch of *Cactus* and *pompon Dahlias* were planted together to furnish flowers for late cutting, a last tie may be given to prevent the breaking of the branches by autumn rains, and at the same time a few tall stakes can be placed at intervals through the border to enable protection to be given easily and quickly if the night is inclined to be frosty. E. BURRELL.

*Claremont.*

**Diseased Begonias.**—A disease has attacked pot *Begonias* of both tuberous and fibrous-rooted sections in this neighbourhood. I have noticed a plant or two here and there in former years, but have attributed it to defective drainage or over-watering in the early stages of growth, and as it

only attacked a few plants and did not affect the bulk of the collection, little notice was taken of it; but this year practically the whole of the pot plants have succumbed for this season at least, and even seedlings raised this year, pricked off into boxes and placed in frames away from the other plants, have not escaped, though they grew well at first. The disease is not confined to the collection here, but seems pretty general throughout the neighbourhood, and in one place where hundreds of plants are usually grown there was not a healthy specimen to be seen a month ago. The loss is distressing, as we depend largely on Begonias to keep up a display of colour right up to the Chrysanthemum season, and have never before failed to do this. So far, none of the plants used for bedding have become affected, and it is to be hoped they will not do so, or we shall have to place less dependence on Begonias for filling the beds with brightness through the season, and in spite of weather changes. The first signs of disease are curling of the leaves and a refusal of the flowers to open properly. This becomes more pronounced and the stems then take on a rusty appearance, the leaves and flowers then dropping, the whole growth getting into a state of stagnation, and finally falling away. Till this year the fibrous-rooted section has escaped, but now all our plants of *B. weltoniensis*, *B. nitida*, and others have gone under. Can any of your readers suggest a remedy or a preventive? For the better behaviour of plants in the open air I have decided for one thing to grow the pot plants in frames another season and treat them to as much fresh air as may be possible, but I should like to hear of something more certain to prevent a recurrence of the disease than this treatment.—**J. C. TALLACK.**

#### CAMPANULA ISOPHYLLA ALBA.

WHEN recently at Mount Stuart, Bute, the residence of the Marquis of Bute, I noticed, among many objects of interest in this magnificent place, that Mr. Heron had planted this *Campanula* on the verge of his plant shelves in his flowering house, where it was doing well and blooming with great freedom. The plants in bloom on the broad stages running round the sides of the house, for it has a central stage, and which consisted of Begonias, Fuchsias, and such like, were standing upon a bed of fine sand and small gravel. All along the verge Mr. Heron had planted this *Campanula* and alternately with it a plant of blue *Lobelia*. Both were doing well, blooming freely, and the effect was excellent. I agree with "E. J." that as a hanging window plant it is excellent, and it can frequently be met with on the costermongers' barrows in the streets, and it is finding its way into many windows. It is the most serious rival the Creeping Jenny has to contend with, as the *Campanula* makes a good town plant. I am desirous of securing the blue-flowered type. I have two very like it in the size of the blossoms and both of a bright pale lilac, but they are unlike it in foliage. One I have received under the name of *C. Barallieri*, but the foliage is quite distinct from that of *isophylla alba*, being darker, more glossy, and the plant is not so continuous in bloom. Then I have what was received under the name of *C. fragilis grandiflora*, which has a trailing habit of growth, is very free and continuous, but the foliage is downy, and in other characteristics it differs, but that all three appear to run much upon the same main lines I am free to admit. The two blue types differ much more from each other than either does from the white. I find the best practice with this *Campanula* is to reduce the balls of roots somewhat in the spring and to repot in some good soil, making it very firm in the pot, then standing the plants on a greenhouse shelf. When they have made a free growth and become pot-bound they flower profusely, and require a good deal of water if the plants are exposed to the sun. I found it perfectly hardy last winter and quite unharmed in a cold house, but plants placed out of doors in a slightly elevated spot suffered severely from the effects of

the winter; but it must be remembered it was exceptionally severe. The plant can be propagated by means of division. **R. D.**

## FERNS.

### SMALL GROWING HYMENOPHYLLUMS.

STRONG-GROWING species of Hymenophyllums are not the only ones deserving the attention of amateurs, for we find among the medium-sized and small-growing kinds some remarkably pretty and interesting plants. Most of these, it may be stated here, succeed best when established on a piece of bare porous sandstone. This is a way adopted most successfully by Mr. Ulbricht, an enthusiastic amateur, of Belmont, Queen's Road, Leytonstone. In every other respect the treatment advocated for strong-growing species applies to medium and small-growing kinds, among which the following are the most distinct and also the best known in collections:—

**H. ASPLENOIDES.**—A charming little Fern native of Mexico and Brazil, where it is found hanging down from mossy rocks and trunks of trees. It is readily distinguished by its peculiar habit of growth, and also by the delicate nature of its narrow, evenly undulated fronds, seldom more than 4 inches long, and of a dark green colour and very shining nature.

**H. BIVALVE.**—The fronds of this distinct species, native of New Zealand, are somewhat broadly triangular, each 4 inches to 6 inches long, 2 inches to 3 inches broad, and have the stalk of their leafy portion only slightly winged above, while that of their divisions is winged throughout.

**H. CHILOENSE.**—A real gem among Hymenophyllums. Its pretty little fronds, seldom more than 2 inches long and 1 inch broad, are triangular, of a dull green colour, with very conspicuous dark veins covering their whole surface. It is a small, pendent tufted species, native of Southern Chili and Chiloe, where it is said to form dense carpets over trees and rocks; it has a great aversion to being watered overhead.

**H. CRUENTUM.**—A most distinct and very interesting species, quite peculiar in its habit of growth and general appearance, inasmuch as its delicately transparent, seaweed-like fronds are simple, broadly spear-shaped, and slightly undulated. They are 3 inches to 5 inches long, 1 inch to 1½ inches broad, and borne on slender naked stalks, and are most interesting through their beautiful venation, their simple and prominent veins reaching from the mid-vein to the margin at regular intervals. The brownish-rosy colour of the old fronds, which remain on the plants for a long time, greatly adds to the beauty of this plant, which is a native of Chili, especially of the province of Valdivia, where it is found growing on trunks of trees.

**H. DICHOTOMUM.**—This is a remarkably pretty dwarf-growing species, which delights in sending its tiny rhizomes through a coating of Moss, covering either a piece of rock or a block of wood, or Tree Fern. It is a native of Chili and Juan Fernandez, and is particularly striking through the beautifully crisped and transparent characters of its finely-divided foliage, by which it can be distinguished at first sight from all other species in cultivation. Its upright-growing little fronds, 4 inches to 6 inches long, inclusive of their stalks, are divided into crisped segments that are sharply toothed or torn at the edges.

**H. MACELANICUM.**—A pretty little species, also known as *H. attenuatum*. It is a native of Chili, Chiloe, and the Organ Mountains, and of a peculiarly rigid, upright habit. It fronds, which are very impatient of water on their surface, are 3 inches to 6 inches long, 2 inches to 3 inches broad, three times divided nearly to the midrib, and borne on upright stalks 2 inches to 4 inches long, margined on each side with an undulated and crisp wing.

**H. MULTIFIDUM.**—This very elegant species, with fronds 2 inches to 6 inches long and 1 inch to 3 inches broad, three times divided nearly to the midrib, with narrow segments, and borne on wiry, naked stalks 2 inches to 4 inches long, is a native of New Zealand and the Pacific Islands.

**H. NEESII.**—A small-growing species, native of Java, Ceylon, Fiji, Borneo, and the Philippine Islands, produces small egg-shaped fronds about 2 inches long, three-quarters of an inch broad, and three times divided nearly to the midrib. These are borne on slightly winged stalks, the wings and leaflets being much crisped.

**H. PECTINATUM.**—No description, however complete, can do justice to the elegant appearance of this beautiful species, native of Chili and Chiloe, which, on account of the essentially distinct character of its foliage, is of great interest. The greyish green colour of its fronds, which measure from 3 inches to 6 inches in length, and are only once divided to the midrib, as well as the beautiful and conspicuous venation of its pinnules, which are restricted to the upper side of the pinnae only, are characters not shared by any other known species.

**H. RARUM.**—A close-growing species, with fronds of a somewhat flaccid nature, 2 inches to 6 inches long, twice divided nearly to the midrib into forked pinnae, showing two or three deeply-cut segments on each side. This species is widely distributed, being found hanging from trees in Chili, Cape Colony, and Mauritius, as well as in Tasmania and New Zealand, where it covers trunks of Tree Ferns with its pendent fronds.

**H. TUNBRIDGEENSE.**—This and the following are the two representatives of the genus found wild in the British Isles. The Tunbridge Wells Filmy Fern, as this species is popularly called, though one of the smallest growing, is also one of the most interesting of the whole genus. It is a compact, elegant little plant, seldom exceeding 3 inches in height and forming dense carpets, often covering large surfaces of rock or stone. We find it first mentioned by Petiver in his "Musei Petiverani Centuria Prima" (published in 1695), under the name of *Darea tunbridgensis minor*, as having been discovered by Mr. Dare, a botanist of the seventeenth century. This is a very cosmopolitan plant, being found in Ceylon, on the Himalayas, in Mauritius, Venezuela, Jamaica, and the Peruvian Andes, also in Madeira and the Azores; while in the British Isles, although it has very nearly, if not quite, disappeared from the vicinity of Tunbridge Wells, it is to this day to be found in Westmoreland, in Ireland, in Wales, and in Scotland, especially in the neighbourhood of Oban.

**H. UNILATERALE**, or, as it is more commonly called, *Wilsoni*, is closely related to *H. tunbridgensense*, yet sufficiently distinct to range as a species. It is altogether of a more rigid habit and its foliage is of a much darker colour, though remarkably transparent, its pinnae being curved and repeatedly divided, but not fan-shaped. Its presence is not limited to the British Isles alone, where it is more widely spread than *tunbridgensense*, for it is also reported from Norway, South Africa, Tasmania, Chiloe, &c.

**H. VALVATUM.**—A very distinct and charming species, native of Nicaragua, Martinique, Guadeloupe and the Andes of Colombia and Peru, where it is found growing on trunks of trees, sometimes covering them entirely. Its drooping fronds, each 4 inches to 6 inches long and 2½ inches broad at the base, are of an exceptionally dark green colour and three times divided nearly to the midrib, with segments on each side of it conspicuously waved. Although not of a hairy nature, this species greatly dislikes water on its delicate and very transparent fronds.

Other species of dimensions similar to the above are known, such as *axillare*, from the West Indies; *Bridgesii*, from Chili and Chiloe; *crispum*, from Tropical America; *denticulatum*, from Java; *falklandicum*, from the Falkland Islands; *gracile*, from Bourbon and Mauritius; *pumilum*, from New South Wales; *sabinæ-*

folium, from Java; Simonsianum, from Sikkim and Khasya; tenellum, from Ceylon; undulatum, from Mexico and Peru, &c., but few of these are in cultivation in this country.

With the exception of *H. scabrum*, all the species above described have smooth foliage, but there exists also a section comprising plants which are very interesting and most beautiful on account of the woolly or hairy nature of their fronds. Most of these are of pendulous habit and grow best on partly decayed wood and on Tree Fern stems; these should never be wetted overhead. The following are the most attractive and best known in cultivation:—

*H. ERUGINOSUM*.—This distinct and well-marked species, native of the island of Tristan d'Acunha, where it is found hanging from rocks and trunks of trees, has pretty fronds each 3 inches to 4 inches long, 1 inch to 2 inches broad, three times divided half way to the midrib, which is winged in its upper part. Their pinne, which at all times are covered with a whitish down, are often much imbricated and the lower ones are frequently fan-shaped. The pubescence on the fronds in a young state is silvery, but with age it assumes a brown or tawny colour.

*H. CILIATUM*.—This species, which is particularly fond of running its slender, thread-like rhizomes into a piece of Tree Fern or of partially decayed wood, is somewhat similar in habit and in general appearance to the better-known chiloense, but is of much larger dimensions. Its fronds, each 2 inches to 6 inches long and 1 inch to 2 inches broad, have the stalk of their leafy portion broadly winged throughout and ciliated, and their pinne and pinnules are hairy throughout, especially along the margin of the fronds. It is also known as *H. Plumieri*, and has a very wide range of habitat, being found in the Eastern Himalayas, in West Tropical Africa, in Mauritius, Madagascar and Bourbon Islands, and common in Tropical America, from Cuba and Mexico to Chili and South Brazil.

*H. ELASTICUM*.—A pretty plant of a woolly nature, closely allied to the better-known hirtellum, and a native of the Seychelles, Mauritius and Bourbon Islands, where it is said to be plentiful.

*H. ENSERTUM*.—A species of medium growth, found on the hills throughout India from the Himalayas southward to Ceylon. Its oblong, spear-shaped fronds, seldom more than 6 inches long and 2 inches broad, have the stalk of their leafy portion winged above and throughout, and more or less densely clothed with deciduous hairs of a rusty brown colour.

*H. HIRSUTUM*.—This distinct and extremely delicate looking species, which succeeds best on a block of wood and in an upright position, is a native of Tropical America, from Cuba to South Brazil. Its pretty fronds, each 2 inches to 6 inches long and 1½ inches broad, only once divided nearly to the midrib, are of a flaccid nature, often pendulous, of a pale colour, and hairy over the surface.

*H. HIRTELLUM*.—A very pretty delicate species with pale green fronds, each 3 inches to 6 inches long, 2 inches to 3 inches broad, three times divided nearly to the midrib, and clothed all over with soft white or tawny hairs, and borne on erect round stalks sometimes 4 inches long and of a woolly nature.

*H. LINEARE*.—This very distinct species, of a particularly hairy nature, is also known as *H. elegans*. Its pendulous and very slender fronds, each 3 inches to 8 inches long and a little more than 1 inch broad, of a flaccid texture, are divided quite to the midrib, their pinne being deeply cut into single or forked linear segments, with margin and surface densely hairy. It is a native of Tropical America from Jamaica and Mexico to Brazil and Peru, and occurs also in Mauritius.

*H. OBTUSUM*.—A small-growing species with spear-shaped fronds, each seldom more than 4 inches long, three times divided nearly to the midrib, and of a particularly woolly nature. It is a native of the Sandwich Islands.

*H. SERICEUM*.—This species, native of Tropical America, from Cuba and Mexico to Peru and Brazil, is undoubtedly one of the most remarkable of the hairy kinds in cultivation. Its splendid fronds, which are exceptionally long and comparatively narrow, being sometimes 2 feet in length and seldom more than 2 inches broad, are once-divided nearly to the midrib and of a pendulous habit. They are produced in such abundance from thin, woolly rhizomes as to quite cover the shady rocks upon which in a natural state this species grows apace, and are rendered very attractive by their pinne, which are sometimes simply notched and sometimes divided more than half way to the midrib, being covered with a tawny and dense silky down, which in its young stage is of a peculiarly light or silvery hue. It thrives best on a piece of sandstone or any other porous stone over which its tiny rhizomes can run freely, without, however, clinging to it, and should be held in an upright position.

S. G.

**Sowing Fern spores.**—The article on page 204, in which some curiosities of Fern raising were dealt with, was of especial interest to me, as the experience of your correspondent was in many respects the same as my own, particularly with regard to the appearance of a crop of seedlings of some kind not previously grown. Aspleniums (that is, the greenhouse and stove kinds) are not mentioned in the article in question, but they may be classed among those that cannot be depended upon to reproduce themselves from spores. Concerning the length of time over which spores retain their vitality, I may mention that I sowed a quantity of spores of *Dicksonia antarctica* taken from a herbarium specimen twenty years old, and they grew as freely as if they had been freshly gathered. Where just one sowing of Ferns is made during the year the spring is the best time for the purpose, but the finest spores can, as a rule, be obtained in the summer and autumn, and if they are then gathered, wrapped up in clean paper, and stored away in a dry suitable place, they will grow as readily when sown in the spring as if they have been just gathered. The soil used for the purpose should be thoroughly baked beforehand in order to destroy all signs of life, otherwise the surface is often quickly overrun with a creeping Moss-like growth which will choke the Ferns. *Pteris tremula* is particularly liable to decay while still in its earlier stages, and to prevent this the growing spores must be pricked off in little clumps.—H. P.

THE MANCHESTER BOTANIC SOCIETY AND ALLOTMENTS.

PERMIT me to bring under the notice of your readers the initiation of a forward movement in relation to this most important subject. Its object may be described as to assist rural effort in connection with the cultivation of the soil. It is well known that during the last few years a very large number of persons have become tenants of small allotments in the neighbourhood of large towns. On the 5th of last month Mr. Gladstone, speaking upon this subject, said: "There never was a period in the history of this country when rural effort in relation to the soil deserved greater support, and those who render help in this direction are public benefactors." The council of this society propose to hold an annual exhibition in the Old Trafford Gardens on a very large scale of the productions grown by the tenants of small holdings, at which prizes will be awarded for the fruits, flowers, vegetables, poultry, cheese, butter, &c. brought forward. Prizes will also be given to the growers of window plants in our large towns. The counties embraced within the sphere of this effort will be Lancashire, Cheshire, and Derbyshire. We are all familiar with the old saying that "the hope of reward sweetens labour," and there can, I think, be no doubt whatever that this special effort will be the means of stimulating the

poorer classes of society in their endeavours to excel in producing flowers, fruits, and vegetables. The council are of opinion that it is the proper and legitimate work of the society they represent to introduce and carry out this project. In order hopefully to inaugurate this important scheme in a comprehensive way, an annual outlay of £200 will be necessary. To meet this expenditure a special fund is being established, and it is hoped that £5000 will be raised for this beneficent purpose. It may be added that a donor of £25 to this fund will become a life member, or be entitled to nominate one. Knowing that the late lamented Prince Consort forty years ago took a lively interest in this subject, I took the liberty of bringing the matter under the notice of Her Most Gracious Majesty the Queen, and had the honour of receiving the following reply:—

Balmoral Castle, September 2, 1895.

Dear Sir,—I am commanded by the Queen to enclose a cheque for £25 as a donation towards the purpose referred to in your letter of August 21.—I am, dear sir, yours faithfully, FLEETWOOD J. EDWARDS.

Since the receipt of this letter, and as the result of several letters I have written to ladies and gentlemen interested in the subject, I am pleased to state that nearly £1000 have been promised. A general appeal will shortly be made to the inhabitants of the districts concerned, together with the list of the donors, and it is hoped that the result will be commensurate with the importance and beneficence of the undertaking.

BRUCE FINDLAY.

Royal Botanic Gardens, Manchester, September 19, 1895.

PUBLIC GARDENS.

TRAFALGAR SQUARE AS A GARDEN.

THIS well-known open space has been called the finest site in Europe, and it most assuredly is the focus-spot of London to-day, and, as such, deserves more attention from a decorative point of view than it at present receives. It is true that a beginning has been made by the adding of a strip of cool, green turf and a few scattered specimens of exotic plants immediately in front of the National Gallery, but the attempts are very half-hearted and quite unworthy of such a magnificent position. What is wanted is more green turf and a few bold groups of Palms, Musas or Bamboos, and some Water Lilies, Reed-mace and other aquatics in the now bare water basins. The main point, after securing green sward, is the bold and simple arrangement of the plants. As a rule, there are two or three times too many flowers and plants used in even the best of our London parks and gardens. There are too many flower-beds, and these are, as a rule, too near together, so that there is no breadth or repose. In several London parks the other day, while admiring the quantity, quality and variety of the exotic plants and flowers therein employed, I was strongly impressed with the absence of the best taste in their arrangement or disposal. There is no good grouping there. Palms, Dragon trees, Bamboos and Bananas are dotted singly and at equal distances on the grass in all directions, here a Palm and there a Banana, so that instead of one seeing a series of separate effects or pictures, the result is constant repetition; you are wearied by seeing the same plants again and again. To simplify and organise this "dot-and-carry-one" system I would suggest that bold groups of Palms, Dragon trees or Tree Ferns, or Bananas and Bamboos, be formed in suitable sheltered positions. By thus making bold groups of one type of plant-form or beauty;

much more than is at first apparent would be gained. Labour and other expenses would be saved in the necessary watering and keeping of these groups as so arranged. The groups would naturally be placed so as to have a background of dark trees or shrubs, and by concentrating or focussing the plants into natural groups, greater breadths of cool, clean sward would be secured. As it is, all our public parks and London gardens possess a rich and healthy profusion of flowers, but in nine cases out of ten half the flowers properly and simply arranged would yield far better results. The Grass also deserves to be fed and kept far better than it is to-day in the parks, and those responsible might with advantage study the College Garden lawns at Oxford or Cambridge.

The great difficulty is that good gardeners are not always, or even often, artists as well, and this artistic feeling is what is especially wanted in our public gardens. It is a question for the authorities answerable for the beauty of our public places whether good and costly materials shall be more than half wasted every year because so ill-arranged. The whole art of artistic grouping is explained in Ruskin's "Elements of Drawing," so that he who runs, even, may read, but excellence in the art itself is proverbially rare. The main thing is to be simple and strong, *i.e.*, make a boldly graduated group of one beautiful thing in a suitable place. A group should be a focus spot—a picture with a good background on which the eye can rest in pleasurable peace. The eye can rest on a broad lawn of cool, well-kept Grass, but these grassy glades are too often dotted over with exotic plants in all our parks, so that the eye simply wanders from one plant to another in bewilderment.

The principle is the same everywhere, but let us remove the reproach that rests upon us with regard to Trafalgar Square. It is the one point in London most deserving of careful and beautiful adornments, and it really ought to be the one place in London for exhibiting the highest garden art in all its perfection. We may never rival, nor would the attempt be wise to imitate, the Oleanders and Pomegranates in tubs, the Orange trees and Myrtles of Southern Europe, but at least it is possible for us to make Trafalgar Square at least during the summer months a place of Palms on cool, velvety turf, with water plants of beauty and variety in the now bald and bare basins. For one person who sees our great parks and public gardens, there are a thousand from all the countries of the world who pass to and fro through this noble square. Let us make of it in reality a place of victory and show that garden art can really triumph over stony death and ugliness.

F. W. BURIDGE.

#### RAILWAY STATION GARDENS.

ONE of the richest and prettiest collections of decorative plants I have seen in a railway station may now be seen at Kingscote, on the London, Brighton, and South Coast Railway. The glass-roofed verandah is literally a greenhouse filled with well-grown flowering plants, such as Pelargoniums, Fuchsias, Petunias, and delicate Ferns, including some pots of Maiden-hair as dark green and as healthy as it is possible to be. A week or two ago the old red Fuchsia fulgens was very handsome, seven or eight plants of it being in full bloom, and the creeping Fuchsia procumbens from Australia is also luxuriant. Plants of Sedum Sieboldi and Campanulas, blue and white, and pendent Ferns fill the corner brackets with their soft flowers and leaves. Tropaeolum tuberosum is very graceful, flowering freely on one or two of the pillars, its vivid orange-scarlet blooms set off by its glaucous foliage.

At one end of the platform over a sunny door a plant of the old Box Thorn, or the Duke of Argyll's Tea Tree, is fruiting freely, its slender stems hanging down laden with fruit nearly as large as Damsons, but of a shining scarlet colour. This plant (*Lycium barbarum*) is one of our most common hardy shrubs, but it is, as a rule, a weedy, unattractive thing, choking up hedges or waste corners with its shoots and leaves. Here at Kingscote, however, the shoots are gracefully rampant and, freely laden with flowers and showy fruits, they form quite an effective addition to the place. Well grown on warm soil and trained in full sunshine on a bit of spare wall, this old shrub may be found far more deserving of culture than is now generally supposed to be the case. Even some of the Kew Garden officials were delighted with this Box Thorn fruit as seen here the other day, and were glad to carry some away for further study. One little fact pointed out to me by Mr. Ward, the stationmaster, was the avidity with which the wasps devoured the ripe fruits of the Lycium, and, judging by their ravages, it is to be hoped they will not extend their attention to the botanically allied fruits of the Tomato, of which there is a very heavily cropped row in the stationmaster's kitchen garden. Celery also is very well grown, and vegetables and fruit trees alike look luxuriant and productive.

Kingscote affords a capital object-lesson for those who believe that gardening might be more generally adopted at railway stations, but of course a great deal, if not almost everything, depends on the individual inclinations of the master in charge. This is shown by the startling variations in decorative treatment adopted at different places. At one station herbaceous plants, at another bedding plants, or, again, Roses and other flowering shrubs are employed, all or any of which are far better than the clinker or shell rockeries, or the cockle shell names of the stations even yet to be seen here and there on nearly all lines.

A good and simple use of the best and most suitable hardy shrubs and herbaceous plants is perhaps as good as anything with which to set off to advantage most station gardens. In some places Ivy, Wistaria, Passiflora, Ampelopsis, Clematis and other good wall climbers are most suitable, root space being limited. On wide warm banks Gorse and Broom, Laburnum, Bladder Senna, Lilac, and Philadelphus may be employed, while the most sheltered and level spots richest in soil may yield the best of Strawberries and early vegetables. I know one station embankment near a signal box in the midlands where an employe planted Strawberries and Whinham's Industry Gooseberries by the hundred, and he now makes a nice little addition to his salary by his thrift and foresight.

One charm about these gardens at or near railway stations is their variety; no two are quite alike, and of course in no two are precisely the same methods of treatment desirable. It is this dissimilarity in soil, shelter, area, aspect, and suitability that makes any gardening organisation so difficult on any railway. Perhaps the best plan would be for each railway company to offer prizes (as some have done) for the best kept plots on their respective lines. The judging of such diversified plots and variable cropping would of course be difficult, but perhaps not much more so than in the case of ordinary allotment gardens in places like Norwich or Nottingham.

Even now, under desultory management, the gardens at many, even if not most, of our railway stations are very beautiful, and photographs and descriptions of the best known examples would doubtless be very acceptable and interesting to all who are fond of the pleasant byways of our garden craft. In any case the station at Kingscote is a good example of the cheerful results attainable under the peculiar structural conditions there available.

F. W. BURIDGE.

The gardens at Versailles.—A friend writing from Paris under date September 23, and who has lately visited these gardens, says: "Yesterday

I was at Versailles to see the *grandes eaux* play. It was my first visit, and the whole place struck me as being false, the keynote being the fountains, which could only play on certain days because there was not water enough otherwise. The enormous expense of keeping up the place struck me too, clipping all those many Yew trees and preventing the alleys of Horse Chestnuts from arching over the paths. The gardens are ugly, the colours of the beds dreadful, and the acres of bare, dusty and unkept gravel walks make the place a literal eyesore. It is tawdry just as a ball room is after a ball, and must have been exceedingly ugly when Louis XIV. lived there, and there was even less shade than there is now. Place for place, both of a wretched kind, Caserta seems far finer: the perspectives are longer, the palace has finer lines, all straight, and the gardens are effective from their huge size, which those of Versailles have not."—B. J.

#### NOTES OF THE WEEK.

**Rose La France** is one of the best of autumn-flowering Roses. I lately saw several standards flowering almost as profusely as one could expect to find them in June in a sunny forecourt garden close to Southampton.—E. M.

**A fine Sunflower.**—Mr. J. Bowler, of Ash Vale, Surrey, has just brought us a Sunflower of great size. The diameter of its seed was 18 inches, whilst the extreme diameter of the flower from tip to tip of the petals was 24 inches. The plant was 11 feet high, and only bore one flower.

**Starworts from Ireland.**—From Newry Mr. T. Smith sends us a gathering of Starworts which are charming in these fine autumn days. Madonna amongst them is the best white we have yet seen, as much superior to A. Purity (also raised at Newry) as that was to all previous white kinds.

**Lilium nepalense.**—We have received from M. L. Van Houtte père, Royal Nurseries, Ghent, under the name of *L. neilgherrense* some very handsome flowers of this beautiful Lily, of which he says there is quite a batch in flower in the open. *Lilium nepalense* was figured in THE GARDEN, January 19, 1889, and *L. neilgherrense*, April 18, 1885.

**Floral decoration of railway stations.**—To encourage the cultivation of flowers at the railway stations on the Midland Railway Company's system, that company offered £200 in prizes among their station-masters, covering nearly 2000 miles of rail. There were upwards of 200 entries for the competition, and the first prize has just been awarded to the station-master at Matlock Bath.

**Chrysanthemums** of the Mme. Deegrange type are now very fine in the Zoological Gardens, doubtless favoured by the fine autumn. The rich yellow G. Wermig we never saw finer than it is here, entirely filling one bed and the plants a perfect mass of bloom. It is much better where there are many beds to devote one or two of them to later flowers, such as this, than to fill them all with summer blooming plants.

**Pentstemon arcticus**.—We have received flowers of this rare and pretty Californian Pentstemon from Mr. James, Woodside, Farnham Royal, Slough. They cluster in threes or more, and their clear rich yellow colour and sweet scent are very precious. It is wiry in growth, with small leaves. Seeds of it were sown last spring and the plants are now in bloom, but we doubt much if they would go through a severe winter unless on a very light soil and in a warm spot.

**Tecoma Smithi**, of which we gave a coloured plate in THE GARDEN of July 13, is again flowering in the No. 4 house at Kew. In this we have a really useful acquisition to the limited list of autumn-flowering greenhouse plants. Plants

little more than a foot in height are crowned with a fine truss of yellow and orange-red flowers. Its origin and treatment generally were alluded to when the plate appeared.

**The Potato harvest.**—In the extensive Potato-growing districts of Lincolnshire and the Fens the work of lifting the tubers has commenced. There is a larger acreage this year than usual, and the crops give promise of good results. Disease has already been noticed amongst some of the delicate varieties, but this does not prevail to any serious extent. Those tubers which have already been lifted are of good size, and free from disease.

**Carrations in Scotland.**—We were pleased when travelling through Scotland to see many beds of splendid Carnations in full bloom. At Carron Lodge, Stonehaven, a town on the sea-coast, near Aberdeen, the plants were in full beauty. One mass consisted of the old Clove, from layers planted this spring, and in another bed the varieties were mixed, none more beautiful, however, than the pure white kind Mrs. Muir.

**Gladiolus brenchleyensis in Scotland.**—This is far more beautiful often in Scotland than in the southern English counties. When walking about Stonehaven a gleam of colour seemed to light up some of the cottages, produced by a line of this Gladiolus in the narrow borders underneath the windows. The corms are never lifted, but each year grow up and blossom in a way that we should like them to do more consistently in England.

**Hydrangea at Saltram, Devon.**—The Earl of Morley sends us photographs of two plants of *Hydrangea paniculata grandiflora* which are growing in an open border there. The panicles are unusually fine, especially in the photo No. 1, measuring in some cases 20 inches to 21 inches in length. The plants are cut down to two or three eyes every spring. They are growing in a moist border, where the *Iris Kämpferi* and *Spiraea palmata* also flourish.

**Cereus triangularis**, which is trained up the rafters in the Cactus house at Kew, now bears several fine blooms and buds, and those who care for these flowers should see it. The buds, nearly 9 inches in length, expand into flowers a foot or more in diameter, yet so refined in colour that there is no suggestion of coarseness. The sepals are sulphur-yellow, the many petals creamy white, whilst the centre of the flower is filled with a graceful mass of slender yellow anthers.

**Aloe africans**, now flowering in the succulent house at Kew, is a striking species. It has a head of spiny leaves on a long stem 4 feet or more in height, and a flower-spike that stands up erect, and so much resembles that of a *Kniphofia*, that, if detached and only the flowering portion was shown, it might easily be mistaken for this last-named plant. The buds are orange-yellow, and open into sulphur-coloured flowers with long exerted anthers of a bright orange-red shade.

**Chenostoma hispidum** and **Hypericum empetrifolium** in one of the houses at Kew, arranged with the bright berry-bearing *Rivina humilis*, make a pretty group. The first named is a dwarf, close-growing plant, with rich, fragrant foliage, the little bushes bearing numerous tiny white flowers. The *Hypericum* (of about the same stature) is covered with spikes of yellow bloom, and the *Rivina*, with its branched heads, gives height and brightness to the group.

**The Dove Orchid** (*Peristeria elata*).—With new and, in some cases, remarkably beautiful hybrid Orchids now appearing so frequently throughout the year, there is a possibility of some good old kinds being forgotten, or at any rate put on one side to make place for one or other of the recent acquisitions. It is to be hoped this will not be the fate of the Dove Orchid, whose form of flower alone shows the aptness of its popular name, and, besides, its flowers come during the late autumn days, which is a quiet time for Orchids generally. We were reminded of the beauty of this old species by seeing a plant

in Messrs. Veitch's nursery at Chelsea carrying two fine spikes, each more than a yard in height and bearing about a score of the bold, handsome ivory white flowers.

**A scented Fern** (*Lastrea fragrans*).—When a scented *Adiantum* was first brought out, not a few were sceptical as to the existence of this unusual trait in a non-flowering plant, above all among Ferns. In the *Adiantum* the scent is rather weak, but in this *Lastrea* it is as powerful and delicate as in the sweetest Rose. It is a tiny plant, its fronds less than 3 inches in length, and a plant with about a dozen of them was growing in a 3-inch pot. It is a native of Jamaica, and consequently not hardy, but may be grown in a cool greenhouse. We noticed this lately in Messrs. Veitch's nursery at Chelsea.

**Verbena venosa.**—This old plant used to figure prominently in summer bedding arrangements a number of years back, but one does not often see it now. It comes in particularly bright during autumn, giving welcome colour when most summer things are on the wane. Mr. Young still uses it in the Zoological Gardens, and its effect was very good there recently in two beds, where it had been planted in association with fine-foliaged plants and the French Marigold. It is also used with good effect on the Victoria Embankment. Such a valuable autumn flower as this should not be lost sight of.

**Crocus speciosus var. Aitchisoni.**—The above named is one of the finest and largest flowered of all the autumnal-blooming Croci, and has bloomed beautifully with me during the past week. Its colour is much lighter in shade than that of the type form, and the flowers are also larger and open better. The petals are most distinctly and beautifully veined. It is as yet, I believe, a rather scarce and comparatively expensive bulb, but as it seeds very freely, the seed-pods coming up with the foliage in the month of March or April, it should soon become more plentiful and easy to obtain.—W. E. GUMBLETON.

**Apple trees in bloom.**—I wish to corroborate what I see published in THE GARDEN in respect to the extraordinary produce of Apples this year. Besides the produce, the weather has been the cause of a very abnormal state of bloom development. Numbers of young trees are now in full flower and some have fruit and bloom together. This feature is very unusual. What is more extraordinary still is that young trees propagated last month by budding have developed bud growth very rapidly and the buds have come into bloom as well.—B. WELLS, *The Fruit Nurseries, Cratley*.

**Lagerstroemia indica.**—The treatment suggested by Mr. J. Lowrie in THE GARDEN of February 10, 1894, appears to have been adopted at Kew, and with success, as there is a large plant of this beautiful Indian tree now flowering profusely in the No. 4 house there. It is planted out in one of the beds and has evidently been hard pruned, which Mr. Lowrie said in the article referred to might induce it to assume a comparatively dwarf habit without loss of bloom. The plant at Kew is most profuse, each of its shoots being terminated by a many-flowered cluster of delightful blossoms which in colour resemble those of the pink Oleander.

**Eucharis amazonica.**—With reference to the illustration of *Eucharis* which appeared in our last week's issue, Mr. W. G. Turbutt sends the following note as to the mode of cultivation: "The *Eucharis* plants were treated by my gardener as follows: Temperature 65° to 70°, soil consisting of rich loam two parts to one part of leaf-mould and manure, adding a little charcoal. Avoid repotting. The plants shown in the group had not been potted for twelve years, but were always surfaced with sheep manure 3 inches deep. After giving them six weeks' rest after flowering (during which time they had a little water), and when they were starting again into growth, they were watered constantly with farmyard manure water, occasionally diluted as the flower-spikes

appeared. They were never allowed to become thoroughly dry after they flowered."

**Cantua dependens** is a pretty plant for a large conservatory or greenhouse. It does best trained up a pillar or, as at Kew, on a trellis where it will get an abundance of light. It is still in bloom in one of the houses at Kew, and this fact indicates its long flowering season, as it usually commences to bloom in the early summer months. The long tubular flowers, disposed in pairs or clusters of three, are of a bright shade of clear rosy carmine at the mouth of the flower, but the tube is of a distinct orange shade. It is a native of the Peruvian Andes and does best in a cool house, but there is little doubt it might be grown in the open air in not a few southern and western gardens if trained on a wall, as, for example, at Offington. A good plate of this plant was given in THE GARDEN of September 12, 1885.

**Some new Caladiums.**—Several of this season's new *Caladiums* were still beautiful with fresh and lovely leaves in a variety of tints when we saw them recently in Messrs. Veitch's nursery at Chelsea. The following were especially worthy of note: *Her Majesty*, which has leaves of an extra light green colour, suffused with a silvery hue and shading to a soft pink with age, old and young leaves alike distinctly attractive in tender and delightful shades. Sir Henry Irving obtained an award of merit early in the season as another welcome variation from the prevailing tint that most predominates among *Caladiums*. Its leaves have a white centre, which fades into light green margined around the edge with a much darker shade of the same colour. *Lady Mosley* is distinct, having bold leaves of a light red colour, the leaf veins standing out being of a much deeper red hue, whilst a narrow well-defined margin of green adds to its colour attractions. Sir Julian Goldsmid has leaves of a deep red colour marbled with white, whilst the margins are well defined by a bronzy green tint. Mrs. C. J. Pierpont Morgan is also noteworthy, with pretty leaves varied in a soft and refined manner.

**Begonia metallica** and **B. echinosepala.**—Some fine specimens of these between 5 feet and 6 feet high constitute a most charming group at the present time in the No. 4 greenhouse at Kew. The plants in question are simply laden with flowers, which in colour are soft pink and white, and therefore most pleasing. In the case of the latter species the papillose sepals are very singular, forming, as it were, a spiny fringe to the flowers. This in the mass has a distinctly pretty effect. Such kinds as these are deserving of far more attention at the hands of gardeners, and being especially suited to the cool conservatory and greenhouse should be in demand. The charming sprays of their flowers in specimen glasses should also meet with approval, and being produced in such numbers would prove most helpful. It is impossible to describe the almost unique effects that may result from a careful use of some of these free-flowering summer and winter-flowering *Begonias*, and particularly is this true for home use. That such plants should be lost sight of is a matter for surprise, as it would be difficult to equal them from a decorative point of view. Of course, it would be easy to get quite small plants, though age with these seems to favour their more free flowering.—E. J.

**Hardy flowers in Regent's Park.**—In looking round to see what colour-beauty was visible from hardy flowers of the present time, we were delighted to find in Regent's Park a picture of present-time flowers that in colour effect was as good as anything we have seen all the year. The best and most artistic of summer bedding is poor and ineffective at the present time, be the weather ever so favourable, as indeed it has been of late, yet it seems absurd to be told in these glorious autumn days that one has come too late to see the flowers at their best. Gardens might always be fresh and gay with a picture that changes with the passing weeks and months. The border in Regent's Park is about as perfect a representation of September flowers as we ever

saw in a public park, and with its sweep of turf in front and mass of shrubs behind forms a picture that must be seen to be appreciated. *Helianthus multiflorus* was to be seen in several good groups, and as a foil to its brightness came the delicate tints of the Starworts, Robert Parker among the tall ones and *Aster acris* in dwarf growth. *Rudbeckia speciosa* and *Sedum spectabile* gave a charming variety, whilst early *Chrysanthemums*, *Zinnias* and the old pot Marigold were additional features of less prominence. Such autumn pictures are all too seldom seen in our parks and public gardens.

**Lycoris aurea.**—This remarkable and handsome bulbous-rooted plant is now in flower in No. 4 greenhouse at Kew. In the rich orange yellow of its large funnel-shaped blossoms there is a distinctness which alone gives value to the plant. The peculiar shade of its flowers is by no means common; indeed, for the nearest approach to it in point of colour one has to refer to the newer forms of the *Montbretias*, and even then we are minus the richness so noticeable in the above plant. Perhaps a more fitting description for this *Lycoris* would be to call it a golden *Amaryllis* of a type midway between *formosissima* and *belladonna*. In the specimens now flowering at Kew the flower-spike, which appears before the leaves, is nearly 2 feet high. Other spikes are in various stages of growth, so that its beautiful flowers may be admired for some little time longer. The bulbs are in pots of about 6 inches across, and to all appearance the plants are easily accommodated. Being a native of China, it may be of doubtful hardiness, unless in warm and favoured districts, where at the foot of a south or south-west wall it may prove, with moderately deep planting, a charming companion to the *Belladonna Lilies*. Where a good stock of bulbs exists it is certainly worth a trial. A coloured plate of this was given in THE GARDEN recently.—E. J.

**Koiphofia hybrida Triumph** (Hort. Leichtlin).—The above-named late blooming form of these fine autumnal ornaments of our gardens is now in flower with me for the first time, and is quite the most beautiful variety I have ever seen. It was raised a few years ago by Herr Max Leichtlin, of Baden-Baden, who has done more for the improvement of these fine plants than any other person. He has done well to name this variety Triumph, as in size, clearness and brilliancy of colour, and form of flower it is as near perfection as may be and leaves nothing to desire. The colour is a clear shade of apricot-orange, with a distinct white marking round the mouth of each flower. As it commences to open in centre of spike and continues to expand upwards and downwards simultaneously, I conclude that *K. comosa* must be one of its parents, as this is a marked characteristic of this very distinct species (which has bloomed with me here this summer for the second time). It differs from *K. Leichtlini*, which commences invariably to open at the top of the spike, and from *K. aloides* and all its numerous progeny, which open from the base of the spike upwards. I also noticed this characteristic in the fine deep orange hybrid *Sirius*, which leads me to the conclusion that in it also the blood of *K. comosa* must predominate. Of all the hybrids known to me Triumph comes nearest to *Lachesis*, also very beautiful and free-blooming, and coming from, I believe, the same garden, but the subject of this note is a great improvement on them all.—W. E. GIMBLETON.

**Amasonia punicea.**—This plant may now be seen flowering freely in Messrs. Veitch's nursery at Chelsea. Gardeners are getting to know of its beauty and great usefulness for giving a welcome colour to plant stoves or warm greenhouses during the latter months of the year—in fact, from now onwards till Christmas. There is nothing to rival it in brilliance but the old *Poinsettia*, and it is so very different from that plant, that those who have need of the one can hardly fail to include both. As hinted above, it will succeed in a warm greenhouse where the temperature does not fall much below 60°, and as regards

cultural treatment, that is much the same as for the *Poinsettia*. It will not, however, stand the somewhat hardy summer treatment that many growers give to the latter. *Amasonia punicea* derives its brightness from red bracts, which, however, are not in a head, as in the *Poinsettia*, but distributed along the stem after the manner of the leaves, of which, in fact, they are miniatures. The spike of these coloured bracts not unfrequently attains to a length of from 15 inches to 18 inches. There were some fully 9 inches in length even thus early upon the plants we saw at Chelsea. These bracts also are not the only colour beauty of the plant, although by far the most persistent, but it has flowers as well of no mean beauty. These, borne from the axil of each bract, are long and tubular like those of a *Gesnera*, but more cylindrical, contracted at the mouth, and of a deep yellow colour. Another valuable point in connection with this plant is the length of time the bracts will remain in good condition.

**Notes from Baden-Baden.**—*Colchicum giganteum*, now at its best, resembles *C. speciosum*, but differs in the larger size, brighter and softer colour, and also the shape of the flowers, the segments being more pointed. In any case it is a superior plant. *Crocus vallicola*, which opened on September 10, is still good; the creamy white striking flowers make the border gay. *Galanthus Olga Regina* seems to be at least three weeks earlier than *G. nivalis octobrensis*; the buds appeared through the soil on September 15, and had we not had such dry weather, they might have pushed even earlier. This hot and dry weather has also caused that loveliest of all *Kniphofias*—*K. Nelsoni*—to show its flower-scapes much earlier than last year. Six to ten came from one root and the plant reaches up to 4 feet. The spikes—very narrow, only 1½ inches thick and about 10 inches long—show brilliant and different shades of scarlet, and the somewhat loose arrangement of the single, rather thin flowers makes it very attractive. The picture is brightened by the grassy, bright green foliage. *Coriaria nepalensis* is in great beauty. It is a suffruticose perennial which in winter dies down to the root-stock; the twigs, which reach 3 feet, are well clothed with pale green, kidney-shaped leaves, and the insignificant flowers appear at the ends of the main twigs. They will soon change into fruits, which hang gracefully down like large Currants, and are of a bright, deep orange-yellow. It likes a shady position. Among the numerous *Solidagos*, *S. Gattereri* must be mentioned. It is of the same colour as the other species, but, owing to a different arrangement of the panicle, has a much lighter, feathery appearance and looks very pleasing.—MAX LEICHTLIN, *Baden-Baden*.

**The weather in West Herts.**—The sixth successive unseasonably warm week, while the last three days—Monday, Tuesday and Wednesday—have been exceptionally hot for the time of year, the highest readings in the shade being respectively 78°, 82° and 79°. Indeed, the maximum shade temperature (82°) on Tuesday was higher than any recorded here in September during the preceding ten years. Previous to this hot spell there occurred two cold nights, when the exposed thermometer showed 2° of frost. Beyond shrivelling a few single *Dahlia* flowers, these frosts did no damage in my garden. The range of temperature throughout the week has been considerable, and on Tuesday last the difference between the lowest night and the highest day readings in the thermometer screen amounted to as much as 37°. The air also has remained during the daytime remarkably dry for September, and on one day the difference between the readings of the dry and wet bulb thermometers reached 14° at 3 o'clock in the afternoon. At this hour the heat has throughout the week been invariably greatest. At 1 foot deep the ground temperature has risen nearly 5° during the last three days and now stands at 62°, or about as high as would be seasonable at the same period in August. The

dews have again been very heavy, but no rain has fallen for nearly three weeks, while the percolation through the heavy soil gauge has ceased altogether, and only a few drops of water are found each morning to have passed through the one containing light soil. During the last five days the sun has shone brightly on an average for over 8½ hours a day.—E. M., *Berkhamsted*.

## OBITUARY.

**Death of Herr Hermann Stenger.**—Herr H. Stenger—who was successively in the service of Messrs. Veitch, at Exeter and Chelsea, Messrs. Henderson, Pine-apple Place, Messrs. Carter, Holborn, and finally represented Messrs. Vilmorin in this country—died suddenly on Monday last at his residence at Dulwich. During the last fifteen years he has been quite incapacitated by paralysis, but, thanks to the generosity of his last employers (whom he served only a few years), he ended his days peacefully and happily.

**Rosa rugosa not fruiting.**—I have for several years had *R. rugosa* and *R. rugosa alba* growing vigorously and blossoming freely, but they rarely set any fruit. I should be very glad to know if any reason can be given for the failure.—A DEVONSHIRE SUBSCRIBER.

**Drying fruit.**—In reply to the query of "North Cotswold" in your issue of September 21, I can inform him that the Waas evaporator, for which Mr. F. E. Clotten, of 65, Euston Road, is agent in England, can be used upon a hot plate and will evaporate Apples or dry Plums satisfactorily; price £3 3s.—J. H. THOROLD.

**Rose Lady Helen Stewart.**—I should be glad to have from those who have tried it their opinion of the *Rose Lady Helen Stewart*. I have found it a pretty and distinct *Rose*, but covered with mildew from the beginning of the season, when there was no trace of it on other *Roses*. I do not think the cause of mildew has received sufficient attention. I am inclined to think that the system of pruning back for autumn blooms, which we have all practised for many years, has a tendency to foster it, as it induces a plentiful growth of young tender shoots, which are the first to be attacked by the disease and are powerless to resist it; in fact, the only remedy seems to be to cut them off. The old summer *Roses* which are not treated in this way are seldom troubled with the pest.—M. E. C.

**Names of plants.**—*Eric James*.—1, *Selaginella divaricata microphylla*; 2, *Microlepia hirta cristata*; 3, *Selaginella Griffithii*; 4, *S. Braunii* (Wilde novum of commerce); 5, *S. sp.*; we cannot identify; 6, *S. erythropus* (umbrosa of commerce).—*Beech Hill, Ilkley*.—*Petunia White Countess of Ellesmere*.—*A. M. Bannerman*.—*Chenopodium epitatum*.—*F. D. Brocklehurst*.—*Clematis graveolens*. See plate in GARDEN, March 24, 1894.—*A. Bowles*.—*Colchicum speciosum*.—*XX*.—1, *Pteris cretica abolineata*; 2, *Pteris cretica*; 3, *Asplenium viviparum*; 4, *Adiantum gracillimum*; 5, *Adiantum concinnum latum*; 6, *Adiantum capillus-Veneris*; 7, *Pteris scaberula*.—*H. Wickham*.—A species of *Phlomis*, but we should like to see flowers.

**Names of fruit.**—*Dr. Legge Paulley*.—Apples: 3, *Fearn's Pippin*; 4, *Blenheim*; 5, *Mère de Ménage*; 1 and 2, next week.—*H. P.*—*Pear Pitmaston Duchess*, Plum rotten.—*J. G. C.*—*Pears*: 2, *Swan's Egg*; 3, *Gansel's Bergamot*; 5, *Pitmaston Duchess*; 6, *Beurré Bose*; 7, *Hessele*; others next week.

"This is an Art  
Which does mend Nature: change it rather; but  
THE ART ITSELF IS NATURE."—Shakespeare.

## ORCHARD AND FRUIT GARDEN.

## PLUMS AND DAMSONS.

THIS year, again, there have been enormous crops of both these fruits, and the usual lament as to prices has been heard on all sides, many growers stating that after paying all expenses nothing has been left for them, and in some cases they have been brought into debt over their consignments. One grower informed me that he sent 4 cwt. of rather small yellow Magnum Bonum Plums to a midland market. The salesman, after paying carriage and deducting his commission, sent the grower two penny stamps as the nett returns for the fruit. Other similar cases could be mentioned where something like the same has been realised for Plums and Damsons in bulk, in consequence of which it is frequently stated that the demand is much below the supply, and that the culture of these stone fruits is overdone. On the face of it many would be disgusted at the very low value but there is another side of the matter, viz.: how far is the grower himself responsible for such unsatisfactory results? First, the fruit is small owing to the heavy crop and inadequate manuring to develop it fully. Secondly, inferior or unsuitable varieties are grown; and thirdly, there is wretched packing. It is astonishing to see the splendid crops of large fruit that Plums and Damsons will bear if heavily manured, but how few give the trees the liberal treatment they ought to do when thus burdened? The answer some would make is that the expense in purchasing fertilisers is too much; but if by expending £5 the grower can make £50, no one can question the wisdom of such an investment. Having had a good deal to do with expenditure and receipts in fruit culture, the above figures represent the average returns made by judicious manuring, and I may further add that Victoria Plums have realised from £18 down to £7 per ton this year, only one consignment falling so low as £7 out of many tons, proving conclusively that it pays to spend a few pounds extra to get full size in fruit in plentiful seasons.

Inferior or unsuitable varieties are another source of dissatisfaction, and in such years as the present are more trouble than they are worth, not paying for gathering and railway carriage, and the sooner such trees are beheaded and grafted with better sorts the greater advantage it will be to the owner. Two varieties that might be worked upon such stocks are Early Prolific and the Czar. Both of these come into use before there is any danger of gluts, and were worth on the average £14 per ton this season. They are excellent market varieties, and the former is a well-known constant bearer that always travels and sells well. Czar is a larger and a little later Plum finding favour in most markets. Victoria still heads the list as a midseason sort, but everyone is planting it, and it is more than possible that it may be overdone in future. Where Pond's Seedling succeeds well, it will pay to work it upon strong, but inferior varieties, as it is later than Victoria, and sells well when that variety is over. Pond's Seedling answers in the west of England, but I have never had it of the size it attains in the north. At the Edinburgh show, September 10 and 11, it was exhibited in grand form by many exhibitors.

Packing is most discredit, and the wonder is that salesmen are able to sell much of the fruit at any price. When in several northern markets last week I saw Plums, Damsons, Apples, &c., put in flats, pots, barrels, and other packages without hay, paper, or any substance to act as a cushion for the fruit; consequently it had travelled badly and looked dear at any price. Plums put in flats and sieves had in many instances rolled about in transit, and where a damaged or decayed fruit was in it had spoiled the sample completely. Damsons were in the same condition, and the salesman who had received them said he could not dispose of them. If the same fruit had been lightly and carefully packed it would have made top prices. The grower himself is entirely to blame in such cases, and until these senders alter their mode of packing we shall continue to hear of wretched prices. Compare the great difference in the Plums now coming from California and Hamburg into our markets. In spite of the longer journey, shipping, and re-shipping, they are far more presentable than much of our produce, although inferior in flavour, and unless we improve in our marketing we shall have more of these foreign consignments to contend against. In Manchester I saw sieves of dark Plums from Germany and other Continental sources selling freely at 2s. 6d. per sieve. W. G. C.

**Apple King of the Pippins.**—How unsuited this Apple appears to be for growing as a standard upon the Crab stock. I have lately seen scores of trees of it, and in no case have I seen a healthy, free-growing tree. Although the trees were bearing heavy crops of highly-coloured fruit, the growth appeared to be stunted and not at all like what one cares to see in a standard. Here in this garden it is the same; the trees as standards make annually very little growth, but bear freely, while the bushes not only crop heavily, but grow freely.—E. M.

**Plum Jefferson.**—I can quite bear out the estimate of "E. M." as to the value of Jefferson Plum. I doubt if a better all-round variety could be named. I commenced picking at the latter part of June from a fine tree growing in our Plum house. For cultivation under glass Jefferson is admirably adapted, the trees fruiting very freely, the fruits individually being of large size and of most luscious flavour. Against an east wall it has been superb, and I have fruits now hanging (September 21) fully ripe on a tree trained against a north wall. Nor is this all, as it has fruited and ripened up grandly—in fact, is one of our heaviest croppers as a standard in the orchard, also as a bush. This is a good record for any Plum. This variety of Plum may have its likes and dislikes like other fruits as to soils, but I never yet met with it other than succeeding well; consequently I feel safe in recommending a trial at least being given.—A. YOUNG.

**The Codlin moth maggot.**—On p. 194 Mr. Groom asks if the above pest is general, and what steps can be taken to prevent its recurrence. In answer to the first query, I hear many complaints in this part (South Herefordshire) as to the havoc wrought by this maggot in the Apple crops, and while so little is done to prevent its increase, I question if the attack will not be worse in the future. In many orchards the infested fruits lie for weeks to rot or be eventually collected for cider making, and while on the ground the larvae have plenty of opportunity to pass from the Apples to more permanent quarters to lodge for the winter and increase and attack future crops. All these fallen fruit should be immediately picked up as they fall, or pigs might be permitted to range many of the orchards, and thus effectually dispose of the embryo enemy. This would only be effectual in standard orchards; where there are dwarf trees or standards with bush trees between, pigs could

not be utilised very well. In those cases where the Apple trees are low it is a very easy matter to most effectually keep the Codlin moth at bay. Out of some 6000 bush trees I think we have not had six Apples infested with the grub in as many years. In spraying for the larvae of the winter moth, prior to and immediately after the blooms setting, with Paris green, 1 oz. to 20 gallons of water, I discovered that the Codlin moth grub never put in an appearance, though the same trees had been severely attacked the previous season, and other orchards not sprayed near had a large proportion of their fruit ruined. This is the sixth year I have employed Paris green, and, as stated, it is a most uncommon occurrence to find an Apple with a grub in it. No doubt there will always be a certain amount of prejudice against the use of Paris green owing to its deadly poisonous nature, but I can assure any readers that with ordinary care no injury will be done to human beings, cattle, or poultry, and the gain in having perfect fruit will not only enhance the value of the same, but also add to the reputation of the grower.—W. G. C.

**Size in fruits.**—One of the effects of the present truly wonderful as well as abnormal season has been the very evident increase in size of both Apples and Pears on ordinary orchard or standard trees in all sorts of soils, but especially on stiff soils. I have seen Hesse, Swan's Egg, Calebasse, Beurré de Capiaumont, Beurré Diel, and similar varieties grown as hardy orchard fruits for market sale in size, colour, and cleanness of skin far superior to what has been grown for many years. This shows the great importance of warmth as well as of comparative atmospheric dryness in helping to produce good orchard Pears. As one result we may find these fruits ripening unusually early; indeed, it seems probable that the bulk of Pears will be ripe a month earlier than would be the case in ordinary seasons. The greater size and finer appearance of the fruit, the Pear crop being generally a moderate one, have proved most beneficial to the market growers, who have been obtaining for these fruits what is to them very satisfactory prices. Apples, too, under similar conditions have shown remarkable advance over what is seen in ordinary seasons in the fruits being of exceptional size and finish. I saw the other day a heavy crop of Ribston Pippin upon an old tree from which for twenty years previously it had hardly been possible to gather a decent sample because of spot or scale, also because of canker. Cox's Orange Pippin has in many places shown exceeding size and fine colour. King of the Pippins and Yellow Ingestre are very large and of superior finish. Lord Suffield and Manks Codlin never have been finer, although these once highly favoured Apples can hardly be sold at 1s. per bushel. Whilst Pears have sold very well, Apples are in such immense quantities, that they find a poor market in spite of their fine appearance. It is a penalty which has to be paid for having too many early ones and a marvellous crop.—A. D.

## PLUMS AGAINST WALLS.

THIS has been an ideal season for Plums, the fruits being both freely produced and well developed. Where a large selection is grown it has been most interesting testing the different varieties, each having a flavour peculiarly its own. The best, however, have been produced against walls. There are certain gardens and districts where good dessert Plums are produced in the open on trees grown as bushes or standards, but these are the exceptions. To produce these special dessert varieties in their best form wall culture is undoubtedly the best. It is astonishing the advantage even a north wall is to Plums, that is when some attempt is made to treat the trees properly, in the matter of a suitable border especially, as herein I think lies the secret. There is the advantage of the season of these fruits being prolonged, which is well worthy of consideration. Green Gage, Kirke's, Jefferson, and Washington are excellent planted against a north wall, so also

is Angelina Burdett. The secret lies in having a raised border sloping from the back to the front, and where a width of 7 feet or 8 feet can be left undisturbed. The roots are therefore encouraged near the surface, which is most essential. The whole surface becomes a perfect network of healthy fibrous roots. Plums, like other fruits, cannot be expected to succeed, even against any aspect, when the surface up to within a couple of feet of the wall is disturbed by annual digging. The soil being loose and rich, the growth becomes gross and unfruitful. A width of at least 6 feet should be devoted to the roots, and then with a judicious system of summer pinching and training, with freedom from insect pests, the production of well-developed fruits is assured. Barrenness is more the outcome of faulty treatment than even climatic influence.

Plums will not succeed on a cold ill-drained soil, but it must not be surmised that I wish to infer that Plums will not succeed on what are termed naturally cold soils, as the soil of this garden is certainly of this description. If there is any doubt about the trees not succeeding well, and this is quickly discerned by the trees fruiting sparsely, also by the fruits cracking and having a rusty appearance, the border should be raised, also drained if necessary. If it is not convenient to work the whole border over, quite large stations should be formed, the soil being taken out to the depth of 20 inches, and when returned have a good addition of wood ashes or burnt garden refuse and old lime rubbish. This may seem a lot of trouble to take, but the results obtained justify the work.

Select trees for planting which have five or six well-balanced shoots. These should be shortened back after the soil has settled down and before growth commences, so as to secure well-furnished trees from the base upwards. A. YOUNG.

**Apple Lane's Prince Albert.**—I note "F. W. B." in his interesting note (p. 221) on back garden Apples includes this in his list, and certainly it is worth more than passing notice, as it grows in any soil or position. I have had it for some years and it has never failed to crop freely, bearing fruits above medium size. For small gardens in bush, pyramid, or cordon form it is the most prolific variety that can be grown. Small trees crop very freely on the Paradise stock.—G. W. S.

**Apple Cox's Pomona.**—The above variety this season is remarkable for its heavy crops. All kinds of trees, and in districts far apart, are bearing heavy crops, the fruit being very highly coloured. I am aware this variety cannot be termed a first-rate fruit, as it so soon loses flavour when stored, and if gathered early becomes mealy and of poor flavour. With care in storing, allowing the fruits to hang on the trees until quite ripe, they are much better in flavour and they keep well into November. Birds and wasps are very fond of these soft-fleshed and highly-coloured fruits, and to preserve the crop, early storing is practised; but it is better to lose a few fruits than spoil the value of the whole crop. The above is doing much better on the Paradise stock than on the Crab, and if allowed a free growth (not cutting hard back), it rarely fails to fruit. Many growers find this a most profitable market fruit for early autumn supplies.—S. H.

**Apple Newtown Pippin.**—I must confess to being astonished that "J. C." should consider the above variety of Apple the best-flavoured sort grown, excelling any of our own productions. As this discussion has arisen from a note of mine some months ago in THE GARDEN, I have taken a good deal of interest in the various remarks made by writers in favour of Newtown Pippin, Cox's Orange and Ribston Pippin, and I must still adhere to my statement that there are no Apples from any part of the globe to equal well-grown and fully ripened fruits of the two last-named varieties. During the past few weeks I have been in the company of some of the best fruit growers in the kingdom, men who, in some in-

stances, have made a special study of Apples and their qualities, and in every case when asked their opinion they emphatically stated that the best Newtown Pippins would not equal our best Cox's Orange or Ribston Pippins in flavour. Again, yesterday I saw one of the leading salesmen and largest importers of Apples, and who always sends me a selection of the choicest imported Apples, and he stated that no foreign Apples would compare favourably with the two British sorts named when grown on suitable land. Many arguments might be brought forward to prove the superiority of our own Apples, but I think it will suffice to state that no Apples from any part of the world realise the price in London as made by choice samples of Cox's Orange Pippin. Though not at liberty to mention names, I have received letters asking for the best Cox's Orange, with an intimation that I might charge my own price for the same; consequently such returns have been received as would appear incredible to those who are not aware of the demand for really the best fruit. As one fruiterer remarked, money is no object with customers who insist on having the best fruit procurable, and it stands to reason that if such buyers found Newtown Pippin equal to Cox's Orange Pippin or the old Ribston they would quickly cease to pay such fancy prices for the latter.—W. G. C.

#### LEAF-SOIL FOR FRUIT TREES.

It is surprising how well tree roots like leaf-soil. Only form a heap 20 yards or more from an Elm tree, and it will not be long before it is fully occupied and practically spoilt by a network of roots. Fruit tree roots are not so hungry and far-reaching as those of forest trees, but they, too, will find their way into heaps of decaying leaves at a considerable distance from their stems. In an old garden I have recently visited, a large Pear tree against a high wall was in a healthier condition than the rest, the fruit being larger and freer of blemish. Eight feet away from the wall there is a sunken pit, to which all the leaves collected in the pleasure grounds are wheeled and left to decay. Each season when the decayed leaves are taken out for the flower garden, potting shed, and such like it is found over-run by Pear tree roots, and it is the food the latter draw from this source that greatly benefits the tree. Acting on my advice, a portion of the many fruit trees in this garden will, in their turn, have a heavy mulching of these half decayed leaves (decaying stable manure might be added with advantage, only it is not forthcoming), and it will not be long before they present an improved appearance. Merely surfacing over the ground to a distance of 6 feet or more from the stems would not meet the case. The roots ought in all such departures to be bared, returning the surface soil on to a dressing 6 inches thick of the decaying vegetable matter. Unless so covered with soil the leaves cease to decay, get dry, blow about, and do little or no good.

One of the best collections of pyramid and bush Apple and Pear trees I have ever seen was then, and is still, kept in a most healthy, heavily productive state by occasional top-dressings of decaying vegetable refuse other than manure. During the autumn and winter a great heap of leaves, sweepings from lawns and walks, road trimmings and vegetable refuse is formed, and this is duly well mixed together and formed into a huge Vegetable Marrow bed. At the end of the season, or soon after frosts destroy the Vegetable Marrows, the heap is turned, all large stones thrown out and sticks, stalks and such like cast on one side. With the aid of the latter a garden smother is formed, and the ashes and burn-bake resulting are then mixed with the larger heap of decaying refuse. In this way enough material is collected to top-

dress about one half of the trees each year, and so well do the latter appreciate this attention that the borders are alive with roots. There is no rank growth of trees promoted, but, on the contrary, the mass of fibres near the surface is just what is wanted to keep them in a healthy, yet most free-bearing condition. A complete failure is rarely, if ever experienced, and it is no fault of the trees if they do not annually produce a heavy crop of fine clean fruit. These top-dressings, besides affording food, act beneficially during the summer, conserving moisture and preventing cracking; also obviating the necessity for lifting and root-pruning. W. I.

**Grape Cannon Hall Muscat.**—How seldom do we see this Grape grown in private gardens really well. From what I have lately seen of it I have come to the conclusion that it requires somewhat heavy soil to grow in. In some localities where the soil approaches sand this Grape is quite a failure. At Mr. P. Kay's Grape-growing establishment at Finchley is to be seen one of the finest examples of culture of this Grape that one can imagine. A span-roofed house 400 feet long and 36 feet wide is planted on both sides with it with the exception of two canes of Black Hamburgh in the centre. These latter are presumably for obtaining pollen to aid in the fertilisation of the Cannon Hall variety, which is a bad setter. No complaint of that sort can be made here, judging from the Grapes which were then hanging upon the Vines. The berries were large, too large perhaps to please some persons. Each Vine was carrying two rods; the close-spur system of pruning is adopted.—E. M.

**Apple Baumann's Red Reinette.**—This is one of the best Apples I have grown in cordon form, and it is worth a note on account of its free-bearing qualities. A few years ago, wanting a fence to hide a portion of the vegetable quarters, I was advised to plant the above, the growths being trained to a few wires. The trees were maidens: some were allowed to make two leads, others one. All have done well, and the fruits being freely exposed, they colour up grandly. I admit the flavour cannot be termed first-rate if the fruits are classed as dessert, but it is not strictly a dessert kind. It is a great bearer with me and is very telling in a collection, its bright crimson colour being remarkable, and when well grown it is above medium size. It makes a fine pyramid and is a useful kind for gardens with restricted space.—S. H. B.

**Apple Margil.**—This old dessert variety is well worth including in new lists where flavour is appreciated, as it partakes largely of the Ribston flavour. I admit it cannot in some soils be termed a heavy cropper, but, on the other hand, it bears regularly and makes a pretty bush or pyramid. When grown as a standard it does not make a large tree, but is a fair cropper in most seasons. This variety is still a favourite in many gardens in spite of so many new introductions, and as it keeps well into the winter it makes a nice dish for dessert, and will often thrive where Ribston fails. For years I grew this variety in espalier form, and as such it is very suitable. It is a neat grower and requires less pruning than many others, doing well on the Paradise stock.—S. H.

**Young Strawberry plants.**—Gardeners who took the hint and planted their young Strawberries on solid ground, prepared some time beforehand, will this autumn prove the superiority of such a root run over loose, freshly-dug ground. The former retains the moisture so much better, besides keeping the roots at home and encouraging the formation of abundance of fresh fibres. Further, those who did not mulch their young beds after planting, especially on light soils, will find that, owing to excessive evaporation, growth is less vigorous than usual. On such soils I would advise mulching even now, not necessarily over the whole area, but for about a foot round each plant. Spent Mushroom manure is the best, as

this is close and does not allow of any escape of moisture. Several copious waterings should follow this operation, and if of liquid manure so much the better. Where this cannot be had, give a liberal sprinkling of artificial manure previous to laying on the mulch. Plants so treated will more than repay the extra labour in the weight and quality of the fruit next summer.—J. C.

### FIGS IN THE OPEN AIR.

TO THE EDITOR OF THE GARDEN.

SIR,—I am exceedingly glad to see that you are taking up the subject of Fig growing. It seems to me somewhat strange how little this popular and delicious fruit is, comparatively speaking, cultivated in England, especially as it is so easily grown. I have about twelve or fourteen trees in my outdoor garden; some of these are grown against walls and some are standards. The late winter was a trying one in the extreme, so much so, that I was reluctantly induced to protect three of them by way of experiment, all of which suffered even to the very roots, but they are now, I am glad to say, vigorously recovering. The others, unprotected in any way, pulled through the winter well and produced excellent crops in nearly every instance, and if I had sold their produce it would have fetched more money than double or treble an equal number of my overburdened Apple or Pear trees. Most of my trees have been planted upwards of twenty years, and those not protected rarely fail whatever may be their situation, either standing alone or against a wall. The former I rarely or ever prune, but the latter I prefer pruning, as the sun ripens the fruit better and quicker. The Brown Turkey I find the most prolific. I apply every other year lime rubble to the roots and occasionally a little ordinary manure. I keep down the tap roots, water liberally with soft rain water and occasionally with soot water. Strong manurial stimulants create wood, but not fruit. Figs, I believe, can be easily and profitably produced and with very little trouble. GWENT.

Newport, Mon.

**Apple Bramley's Seedling.**—Those who planted this variety a few years ago will have good reason to congratulate themselves on so doing. It is a very free-bearing variety in a young state, and will keep well into May given a cool store. This variety was brought into prominent notice at the Apple congress held at Chiswick in 1883. The fruits are very handsome, large, solid, heavy, angular, deep green, with dull red streaks, and of very good cooking quality. When in bloom it is quite distinct from many others, having a large flower of great substance. It is doing very well as a bush on the Paradise stock and is most prolific. It is also doing well as a standard, making a vigorous growth.—G. W.

**Open-air Peaches.**—This will be a record year amongst Peach growers, both as regards the quantity and quality of fruit on open walls. Of course this remark can only apply to places where the trees are well looked after all the year round, for the time has gone when, owing to genial springs and even seasons throughout, good gatherings could be made from semi-neglected Peach walls. This season healthy trees which have been well mulched and freely supplied with water have produced large fruit of extra good colour. This is true even of later sorts, such as Barrington and Late Admirable. In a gentleman's garden near Retford, by no means a good locality for gardening, the Peach trees on walls are a sight worth seeing. This is due to the continuous attention bestowed on them. In spring, as soon as disbudding is completed, almost daily syringing of the foliage is practised, except when the weather is sunless and cold, this being continued right up to the time the fruit begins to colour. This is perhaps too much to expect from gardeners where labour is short, but if spring washings are not frequently done, aphid is sure to get a footing

and ruin the crop, if not the trees. At the place under notice the wood is laid in thinly, the trees well mulched and copiously watered in dry weather with farmyard liquid. Depend upon it, were these simple yet essential cultural details attended to regularly and well, many gardeners might still grow good Peaches on open walls who have abandoned the attempt owing, as they say, to the unsuitable seasons. From various sources I learn that the demand for Peach trees for planting on walls has been far greater during the past two years than for many years previous, which is certainly a hopeful sign.—J. C.

### NOTES OF THE WEEK.

**A note from Scarborough.**—This golden summer weather has made our northern gardens glow with unwonted brilliance. If only a coloured photo were possible! The failures of last year and the damages of last winter are now compensated by this rich harvest of luxuriance and wealth of beauty.—EDWARD H. WOODALL.

**Polygonum orientale** makes an imposing autumn group when grown as well as at Kew, where two beds are quite a feature in the herbaceous grounds. The plants are nearly 10 feet high, well clothed with large deep green leaves and flowering freely. It wants a light, rich, warm soil in order to grow to such great dimensions.

**Chrysanthemum Coquetterie.**—I enclose a bloom of this which has been open about ten days. The plants are about 3 feet high, and the natural time of flowering is October. Crown buds are white with saffron centre and the terminals bluish.—R. OWEN.

\*\* A remarkably fine flower for so early in the season.—Ed.

**Stokesia cyanea** is a beautiful flower of the present time, but not usually seen in good form, as it often gets spoilt by rain in the average autumn. It has large and showy blooms of a pretty blue colour. A good bunch of fine flowers was prominent in Mr. M. Prichard's group at the Crystal Palace fruit show.

**Caryopteris mastacanthus**, favoured by the unusual heat, is flowering well this autumn, and we noticed several pretty bushes of it in full bloom at Coombe Wood. The flowers, small individually, but borne in crowded clusters all along the shoots of the current season's growth, have a distinct and graceful appearance. They are of a pretty shade of lavender-blue.

**Dahlia Watford Beauty.**—This single Dahlia, of which a quantity was shown by Messrs. Cutbush at the Crystal Palace fruit show, is one of the most beautiful kinds we have seen for a long time, distinct, effective and most harmonious in colouring. The flowers are of a bright shade of orange-buff, true old gold colour with a crimson zone at the base of the petals, which imparts a particular richness to the centre of the flower.

**Desmodium penduliflorum** is one of the most conspicuous shrubs now blooming in the Coombe Wood Nurseries. There is an old stool of it and the shoots die back to the ground every year. In spring, young growth starts up vigorously, and by autumn the shoots are 6 feet or more in height. They are loosely supported, and the long racemes of bloom fall over in a most graceful way. The flowers are of a deep rosy purple colour.

**Vernonia fasciculata** is an uncommon autumn-flowering composite now blooming in the herbaceous grounds at Kew. It would be more appreciated if naturalised than growing in a choice bed or border, but we noted it for the deep rich violet-purple tint of its flowers. These are Daisy-like, but double, and borne in crowded heads on the top of shoots that resemble those of the Osier alike in their tall, slender, unbranched

growth and profusion of long, narrow, drooping leaves.

**Flowering hardy Hibiscus.**—I send you a spray of the North American Hibiscus (hybrid, I believe) which is flowering fairly freely this year. It would be a handsome plant if its lower leaves did not begin to turn yellow as the flowers appear. The plant has been in a corner in the kitchen garden for the last five years, and has flowered three times, but never so freely as this year.—W. SHIRLEY, *Fareham*.

**Rudbeckia occidentalis** deserves to be grown along with the best Coneflowers judging from its appearance at Kew, where a fine plant is conspicuous in the Coneflower group. In leafage it is quite distinct from other kinds generally grown, as it has compound leaves made up of two pairs of broad-lobed leaflets and a larger terminal one. The flower has about ten long, broad rich yellow rays and a rounded cone of a greenish shade in the centre.

**Cereus rostratus.**—This showy Mexican plant has been producing its huge yellowish cream blossoms recently in the succulent house at Kew. The flowers were produced quite near the glass, high up on the quaint fleshy stems, and must have been nearly, or quite, 10 inches across at the widest part. The species evidently requires a considerable length of rafters to develop its peculiar growths, and though very showy when in bloom, it can hardly be regarded as free flowering judging by its size.—E. J.

**Single Cactus Dahlias.**—Messrs. Dobbie and Co., of Rothesay, who introduced this class into our gardens, and who have raised many fine varieties, send us a gathering of flowers of these. The old type of single Dahlia was very regular in form, but in the Cactus varieties there is a decided break away from this, which will no doubt cause them to find many admirers. Among those sent there are yet many poor washed-out colours, but we are glad to see that rich and pleasing self-coloured varieties are being raised.

**The Italian Pimpernel** (*Anagallis Monelli*).—There are several forms of the Italian Pimpernel with distinctly coloured flowers, and all are hardy annuals, well worth attention in the garden. They would make pretty edgings if sown in a sunny spot, as they trail about in the same way as our native kind. At Gunnersbury House Mr. Hudson has sown a line in front of one of the borders, and the variety is a very fine one, with large flowers of a deep self Gentian-blue colour, very rich in sunshine when many flowers are open.

**Perpetual Pinks.**—It is a great gain to have the Pink season extended into the latest days of autumn, for one can hardly become tired of the refined colour and delicious fragrance of this flower. The variety Ernest Ladhams is now becoming well known. At the Crystal Palace show Mr. Ladhams showed this kind and seedlings from it of the same perpetual character, making altogether a display of Pinks that suggested early June days rather than the close of September. The flowers were as fresh and fragrant as in early summer days.

**Kniphofia caulescens.**—This handsome and distinct species is well grown by Mr. Latham at the Birmingham Botanic Gardens. By its characteristic boldness generally, as also on account of its spreading leaves, the species is well suited for isolated positions, and being perfectly hardy may be planted in high and dry positions in the rock garden where few plants thrive. But in these it must not be shut off from a good depth of soil for its roots. Under Mr. Latham's care it receives a position quite sheltered from keen and cold winds, as these inflict greater injury than severe or prolonged frost. South or south-west positions suit it admirably, and in both positions it was unharmed during last winter, the plants receiving no protection whatever.—E. J.

**Dahlia Mrs. Francis Fell.**—The objection that is raised to the majority of the Cactus-flowered Dahlias—that they hide their flowers among the shoots—is a reasonable one, and a fault

that raisers should seek to eliminate in new kinds. It is most essential to do so if these Dahlias are to become popular as garden flowers. The variety under notice is a new kind that is free from the drawbacks above mentioned, judging from a plant we lately saw with Mr. Hudson at Gunnersbury House. The upper portion was a mass of flowers, thrown out well from the shoots. The flowers are pure white and of the finest Cactus form.

**Acidantha bicolor** has again been flowering freely in a frame at Kew, and, although not quite hardy enough for open-air growth, is a graceful and beautiful plant that many will like to grow. In habit and appearance it is intermediate between an *Ixia* and a *Gladiolus*. The flowers are thinly arranged on the spike and decidedly pendulous. They consist of six equal pointed segments of a creamy white colour, whilst at the base of each is a triangular blotch of violet-purple, which gives a decidedly rich effect. A coloured plate of this plant was given in THE GARDEN for May 18 of this year.

**Genista tinctoria elata**.—The common Dyer's Weed is a nuisance in poor pasture fields, as cattle will not eat it nor mowing kill it. Its presence plainly indicates poverty of soil, and we have seen it charming in sheets of yellow upon poor stony banks where little else would grow. The variety under notice is merely a tall growing form, but its value as a garden plant is greater in consequence of its extra stature, and it is also one of the latest flowering representatives of the Broom family. Mr. Prichard showed shoots of it a yard or more long, and covered with rich yellow flowers, at the Crystal Palace show, and we have seen the plant very beautiful in the rock garden at Kew this season.

**Acer rufinerve** is a beautiful Maple growing in the Coombe Wood Nurseries. It has the peculiar and pretty bark variegation so characteristic of the Pennsylvanian Maple, even more pronounced than in this species, whilst it is a much better tree, as it grows faster. The bark of the stem and of the mature branches is deep green striped with white, and that of the young growing shoots is silvery white, covered with a glaucous bloom. The leaves are long, slightly three lobed, and turn rich yellow in autumn. Such a pretty tree as this ought to be frequently seen, and with the added beauty of its bark variegation it would prove attractive the whole year round.

**Abies brachyphylla** is one of the most promising of the newer conifers, and, judging from the fine breadths of it we lately saw in the Coombe Wood Nurseries, a hardy and handsome kind that planters would do well to try. Messrs. Veitch consider it a better tree than Nordmann's Silver Fir, and the present state of a large break of this kind beside that of *A. brachyphylla* points to the same conclusion. In habit of growth *A. brachyphylla* may be described as intermediate between Nordmann's Fir and *A. Pinsapo*. The leaves are deep green above, but beautifully glaucous on their under sides. The fine shoots of the current season's growth show it to be a strong and rapid growing tree, whilst it is quite distinct from other kinds of *Abies* grown in gardens.

**Autumn Roses**.—Mr. Orpen, of West Bergholt, sends us a charming collection of Tea Roses from the open air, showing how well they flower in his district this fine year. Amongst them not the least beautiful are some Roses with a single tendency, and also a particularly splendid one which Mr. Orpen considers the same as Bardou Job, and as to which he makes the following remarks: "Mr. F. Cant, who gave me the buds from which I raised my plants, considers it distinct from Bardou Job, and showed it at the Crystal Palace as a new variety in 1894, but the judges did not consider it distinct. I am not sufficiently acquainted with Bardou Job to form an opinion, but I know this I send you is one of the grandest garden Roses I have ever seen; the

foliage is very fine and large and the plants are always in flower. The growth is very strong; some made this season is over 6 feet high."

**Citrus triptera**.—The past winter has not diminished the size nor in any way injured the fine plant of this hardy Orange growing in Messrs. Veitch's nursery at Coombe Wood, and it is now bearing many fine fruits. It is a remarkable and beautiful shrub, worthy of a place in the choicest collection. Its leaves are trifoliate, of a light green and almost persistent; the bark of the shoots, too, is of a deep green colour, and the flowers are produced singly along the shoots, the bark of which makes an admirable foil, as the leaves are but thinly borne. The shoots are also armed with formidable stout spines, some of them nearly 2 inches long. The specimen at Coombe Wood is about 7 feet high, with a dense pyramidal habit. A coloured plate of this *Citrus* and a woodcut showing its fruits were given in THE GARDEN for September 22, 1894.

**A fence of Dahlias**.—It is not often that one sees Dahlias used to make a fence or screen, but at Gunnersbury House they have been used by Mr. Hudson with splendid effect, and nothing could be finer in these glorious autumn days than this fence of Dahlias. On the carriage front of the house an iron and wire fence with a Grass verge in front of it divides a piece of grass land from the carriage drive. A border of soil little more than a foot in width suffices for the Dahlias, which are tied to the fence and revel in their open quarters with abundance of sun and air. Their limited root-run conduces to profuse flowering, and they make a fine display, as only the best of the Cactus and decorative kinds have been planted. It is possible from this fence to cut daily supplies of flowers without in the least diminishing the beauty of the display, whilst it suggests another way of autumn gardening. Much more should be done with autumn flowers. In not a few places of late all that we could see of flowers were the remnants of the summer months.

**Two beautiful weeping trees** that ought to be freely planted are *Pyrus salicifolia pendula* and *P. prunifolia pendula*, of both of which we lately saw beautiful examples in the Waltham Cross Nurseries, and although young specimens, they were distinctly beautiful. The Willow-leaved Weeping Pear, as we may fittingly style *P. salicifolia pendula*, is different from any of the large numbers of pretty Crabs, as it has long leaves like those of the Willow, and they are of a silvery white colour. The weeping habit is very pronounced, and to get the fullest beauty from the tree it should be worked on a stem 8 feet or 9 feet in height at least. Its fruits are Pear-shaped and yellow when ripe. *P. prunifolia pendula* more resembles the ordinary Crabs in leafage, but is very pendulous in growth, and would also be seen to the best advantage on a high stem. Its fruits are like those of the Siberian Crab, and take on when ripe a bright colour, rich red on the sunny side.

**Magnolia Watsoni and M. parviflora**.—These have already proved to be sterling additions to the hardy flowering Magnolias, but we were surprised to see a number of fine blooms of *M. Watsoni* shown by Messrs. Veitch at the Crystal Palace fruit show. Plants of this species and of *M. parviflora* as well are now flowering in Messrs. Veitch's nursery at Coombe Wood, and it was from these plants that the blooms shown were cut. Probably this present blooming may be but a freak, wholly or in part caused by the unusual autumn heat. As is well known, these deciduous Magnolias flower in spring upon wood of the previous season's growth, but the plants now flowering at Coombe Wood have produced blooms at the end of the current season's shoots. If they do this naturally in other years it will greatly add to their value, but of course as yet we have no proof that they will do so. All who can grow Magnolias should add these two to their collections, for they are both very beautiful. The flowers of

*M. Watsoni* are the larger of the two, but those of *M. parviflora* are not so small as the name would suggest, whilst they are of a purer white than these of *M. Watsoni*.

**Kniphofia Nelsoni**.—I cannot at all agree with Herr Max Leichtlin's description of the above-named plant on page 252 of your last issue as the loveliest of all *Kniphofias*, nor can I understand for a moment how such a consummate judge of the relative merits of these plants (as he undoubtedly is) could commit himself to any such expression of opinion. I have now thirteen spikes of this miniature variety (or species, as it most probably is) either in full flower or coming on. These are produced by nine plants in their second year from seed received direct from its introducer—Mr. Nelson—so it is decidedly quick to mature itself and most free-blooming, as one of my seedlings bloomed last year in the first year of its existence. With these two points in its favour duly noted its merits end in my opinion, as its colour is dull, its flowers small and thinly produced on the spike, and in beauty, to my mind, it cannot for a moment be compared to the brilliant little *K. Macowani*, to which it comes nearest in appearance and habit of growth, though smaller in every way and with much narrower grass-like foliage, which quite disappears in the winter. Herr Max Leichtlin says "the plant reaches up to 4 feet;" whereas my highest spike is just 22 inches, or less than half as high. Then the dimensions of the spike are not more than half those mentioned in THE GARDEN. I consider it to be a rather pretty little botanical curiosity and nothing more.—W. E. GUMBLETON.

#### THE BOG GARDEN.

TO THE EDITOR OF THE GARDEN.

SIR,—Seeing in your number of August 10 that suggestions are invited by those who have made and succeeded in a bog garden, I am tempted to offer you my experience. Four years ago, having finished a rather large fernery, formed in a somewhat circular shape, with a picturesque-looking log hut at the further end, it occurred to me that the large piece of grass in the centre might be partly made into a bog garden. I began by excavating the soil, and made an oblong basin 30 feet by 20 feet and 4 feet deep. This was cemented with Portland cement, a plug being left at the bottom to allow the water to escape when required. I then built a second wall inside the basin about 4 feet to 5 feet from the edge of the basin, leaving occasional holes in it for the water to pass through. I then filled up the space between the two walls with a mixture of peat, earth, and some soil procured from a neighbouring marsh. The basin is filled by means of water from a well about 50 yards from the fernery. It is pumped up into a small zinc cistern, at the bottom of which a 2½-inch lead pipe is fixed. This pipe passes below the surface and communicates with the inner basin. The water escapes into the peat placed between the two walls and forms the bog. The bog is surrounded by a narrow gravel walk, on the outside of which an alpine garden is made of blocks of sandstone. The basin once filled and the bog saturated, there is no difficulty in keeping it supplied. In the centre basin I have Nymphaeas of different sorts, *N. odorata rosea*, *N. Marliacea*, *N. pygmaea*, and *N. Chromatella*. In the bog I grow different kinds of *Cypripediums*, *Pinguicula*, *Sarracenias*, *Trilliums*, *Fritillaria*, *Iris Kämpferi*, *Acorus*, *Osmunda*, and many Gentians, *G. Pneumonanthe*, *G. verna*, &c., that love the drier edges of a bog. The ground, fortunately, slopes towards the bog, and has to be approached by rough steps through the rock garden, and the effect on entering through the outer fernery is very pleasing. I think the close vicinity of the water and bog suits the alpine. I have been very successful in the culture of alpine, and lost very few rare ones through last year's severe winter.

Woodbastwick Hall, Norwich. M. M. C. C.

## CASTLEWELLAN, CO. DOWN.

It is not easy to do justice to Castlewellan, the seat of Lord Annesley, with the camera, beautiful and true as photographs may be, since the pictures on tree and lake, on the cloud-swept mountain-side and lawn, and on the sunlit sea are so evanescent and varied, and above all so rich and sombre, or so fairy-like and tender in tone, that the best of landscape artists even might fail in telling even half the tale.

Castlewellan is a place of diversified surface, set in amongst the mountains behind Rosstrevor, and it is the home of perhaps the richest and rarest collection of exotic trees and shrubs in Northern Ireland. This much will, indeed, have already been realised by all careful readers or students of THE GARDEN who will have noticed the many illustrations from the

Islands, as seen under the best circumstances of sunshine, lace-like mist and deep-toned shadow from the best points of view.

One of the illustrations shows the modern mansion at Castlewellan erected some half century or so ago near the site of an older country residence, the site or ground plan of which is still marked out by dwarf hedges. It was in the park lying in front of this old residential site that the noble Daffodil, now known as the Countess of Annesley, was found a few years ago naturalised by the thousand, and it is from the park mainly that the bulbs of this variety have been distributed. How, when, why, or whence it came to Castlewellan is one of the many plant mysteries that lie enshrouded in a hazy past. It is not at all an easy matter to give any definite notion of the extent and

30 feet or so high, as shown in the engraving. Nowhere else except perhaps at Elvaston Castle, in Derbyshire, have I seen the Weeping Ash trees so fine and bold as here. Castlewellan is essentially a tree and shrub garden. There are flowers in plenty in the conservatories and choice Orchids, Palms, Ferns, Pitcher Plants, and dainty Nymphaeas also, but it is the more permanent phases of garden art that are followed with zest at this remarkable place, and it is a style that best emphasises the vast proportions and subtle grandeur of the surrounding scenery.

To speak of the rare and well-grown conifers to be seen here would require a volume, and the nursery of young trees and shrubs alone in the sheltered enclosed gardens would require a catalogue to itself; indeed, it really has one, as those who have the privilege of seeing a copy

Castlewellan, Co. Down. From a photograph by Lord Annesley.

place that have been published from time to time. Even the town of Castlewellan is remarkable, and from elevated points in its vicinity the most varied and delightful views are obtainable. To the east lies the bay of Dundrum, with its rich and fertile valley running down to Downpatrick, while to the northward lie the rugged and picturesque hills encircling Slieve Croob and the woods of Castlewellan demesne itself, with Slieve Donard in the distance, while to the south are all the tops or summits of the great range of the Mourne Mountains that really spring from their ocean bed, just as Mercury is fabled to have sprung full fledged from the head of Minerva. Height after height, rising and falling in all their variety and grandeur—an alpine scene not easily equalled in the British

variety of surface to be met with at Castlewellan. Woods, deer parks and Fern-clad hills lie around one in all directions except where there are glimpses of the sea. The red deer raise their heads above the Brake Fern and stare down at you from the slopes of purple Heather, and there are golden pheasants from Japan with their Colchican cousins free and happy in the woods. On the lake and ponds everywhere there is bird life, and, as I have said, the grounds are enriched with hardy trees and shrubs from nearly all temperate regions. The Monkey Puzzles or Araucarias from Chili (shown in the engraving, p. 268) are especially healthy, dense, green, and handsome as their lower branches sweep the lawns, and there are enormous specimens of the

of the red book of Castlewellan will remember. There are rare Water Lilies, other aquatics in the ponds, and graceful Bamboos along their margins or in the conservatory near to the house. It is about a year ago since two friends and myself made a professional pilgrimage to Castlewellan from Newry, a drive of sixteen miles or so *via* Hilltown, over the mountain roads and through the Flax fields. Nothing could have well exceeded our pleasure at the noble and varied views or our satisfaction at seeing such a rich collection of plants well placed in the open air. Arundo conspicua by the pools waved its plumes in the sunny breeze; Parrotia persica and the Virginian and Japanese Vines shone with glowing colour everywhere or hung their empurpled banners on the outer walls, clambering vigorously along wall tops

here, and there was that noblest of all wild Vines of Japan, *Vitis Coignetiae*, its great leaves 10 inches or more across and glowing in all shades of bronze, purple and gold. It is a great pleasure to some of us to know that this Vine is established in many Irish gardens, thanks to the owner of Castlewellan. At Narrow-water Park, near Newry, it spreads just now many feet over a high wall and over a Portugal Laurel, its long shoots wreathed with gigantic foliage. One or two of its largest leaves actually measured 11 inches in length by quite as much broad, and were just changing from rich green to shades of bronze and purple; indeed, its leaves as grown there were fully as fine as those brought direct from the woods of Japan by Mr. J. H. Veitch, of Chelsea, and Mr. W. Goldring, of Kew, some few years ago. While speaking of this gigantic, highly-coloured and ornamental Vine, I should like to say that I have often wondered how, when, and by what lucky chance it years ago came to England and was planted at the base of the Scotch Firs, over whose branches it now clammers and dangles in royal wreaths at the Knaphill Nursery of Messrs. Waterer. It would be very interesting to hear Mr. Waterer's history of this plant as it now exists with him. As this Vine is likely to play a very important part in gardens for years to come, I may be the more readily excused for pointing out that it may be increased in several ways, viz.:

1. By layers from plants already established, a slow but sure method if intelligently performed.
2. By seeds imported direct from Japan, where it climbs to the tops of the trees in thin woods and fruits very freely.
3. By grafting dormant cuttings or scions on to cuttings or rooted eyes of the true Grape Vine in the early part of the year.

Rich as Castlewellan is in autumn-time, when leaves are crimson and brown and russet or gold everywhere, it is perhaps in the spring-time when it looks its best. To see its deep green woods jewelled with Anemones and Bluebells, and bursting buds and young leaflets unfolding everywhere is to feel and to know something of the very poetry of the garden. The Rhododendrons alone are in themselves suggestive of royal splendour, as they glint here and there among the trees beside the wood walks and drives, or rise in bold clumps and informal masses from the mossy lawns. But after all one must see the place in order to appreciate its many-sided and ever-varying charms.

F. W. BURBIDGE.

## KITCHEN GARDEN.

### GOOD SALADS.

Not only are salads liked during the summer, but they are valuable at all seasons. Of late years there appears to me to be a larger demand for salad, and though it is difficult to provide such after a severe winter if we rely upon outdoor supplies, there are now more opportunities for providing supplies by those who have cases for Peaches or other fruits, and much may be done with ordinary movable frames, damp being even a worse enemy than frost. Lettuces are grown so quickly and of such good quality, that there is less difficulty in having a good supply all the year round. I admit by attention to sowing, Lettuce can be produced with little trouble from April to October. My notes will refer more fully to winter and spring supplies. To get Lettuces in quantity during the winter one must rely upon glass, and, as previously stated, only protection is required for winter

supplies. As good Lettuce may be had from the open ground well into November, it is the mid-winter supplies which must be provided for. The plants must not be too large, as if fully grown they damp badly and the frost soon injures them, so that even here it is necessary to sow frequently to get suitable material. Many fail with salads by sowing in too large quantities and at too long intervals. A little and often is the best way to get fresh material. For winter, three sowings—one in July, another in August and a third early in September—will give good plants. The July sowing will provide Lettuces well into the month of November, though it may be necessary to cover from early frosts with lights or mats. The August sowing should be a liberal one. The plants can be lifted early in October with a ball, and may be housed in frames or cool Peach cases. These will give the supply after the open-air plants are cut. I place much importance upon the September sowing on a dry sloping border, as these plants will be valuable early in the spring, at a season the Endive is over and salads are scarce. I admit there are losses, but these must be met. Should the plants be killed, no time must be lost in sowing in heat in January, pricking out into a frame on a warm bed. Good plants may be had at the end of March if an early Cabbage variety, such as Golden Queen or Early Paris Market, is sown. To preserve for early spring cutting it is advisable to plant out in October in front of a glasshouse or under a warm wall. To preserve them in severe winters I have placed dry leaves between them. Of course, if glass can be spared it is much better, but in mild winters, plants sown thinly on a well-drained border often live in the seed-beds. These, lifted carefully and planted on a warm bed, soon turn in.

Endive is, next to Lettuce, the most important, and as this can be had good well into the spring, there need be no lack of material for the salad bowl. For mid-winter and early spring supplies the Batavian Round-leaved is much superior to others, having large solid hearts and more hardy. Doubtless the Green Curled is more showy, and may be had in quantity well into autumn, but for keeping it is not suitable. I recently saw a very fine strain of Batavian growing in the R. H. Society's gardens at Chiswick, the leaves being equal to the best Cos Lettuce. To get a long succession, much the same culture is required as for Lettuce—three sowings, June, July, and August. Blanched heads are readily affected by frost, so that the plants must be covered for blanching in the quantities required. Mustard and Cress in variety are so readily grown they need not be noted. Beetroot, a valuable addition, should be small and bright coloured. Tomatoes are now grown nearly all the year round; the small kinds are valuable adjuncts to the salad bowl. Many other aids may be introduced for winter salads. Chicory is good, also Dandelion for spring salads. Water Cress may be used more freely. I have grown this in pots for early use. It grows well in a frame, kept moist. Corn Salad sown specially for winter supplies is useful when Lettuce or Endive is scarce. Sown in June it will give a good supply early in the year.

G. WYTHES.

**A good autumn Pea.**—The value of *Ne Plus Ultra* for autumn supplies is known by most growers who require late Peas. In certain localities it is difficult to keep up a good autumn supply, as the old favourites fail, being badly attacked by insects and mildew. For two seasons I have depended upon *Autocrat* for late supplies. In our soil, where most late varieties fail, a good autumn variety is a great gain. As *Autocrat* is

a splendid cropper, I shall grow it in preference to the older *Ne Plus Ultra*, the newer variety being more prolific, dwarfier, and doing well in adverse seasons. It is of very robust habit, much branched, and only 4 feet high. I am much in favour of branched varieties, as they usually produce in pairs, yield longer, and withstand drought better. *Autocrat* is a blue wrinkled marrow with a large pod, deep green, of nice shape, similar to *Ne Plus Ultra* in colour, but broader. The quality is first-rate. At this date (September 20) I have a very good crop and of excellent quality. Last season it was also good, the plants producing well into October.—S. H.

**Tomato Ham Green.**—This variety is much in favour at Hatchford, Mr. Theobald growing it to the exclusion of all others both indoors and in the open air. Heavy crops were ripening on open walls, and I counted clusters with nine large fruits, all big enough for a good market sample. This Tomato is much liked by market growers, and no one can err in planting it largely either for private use or for profit.—J. C. B.

**Cardiff Castle Cucumber.**—This is a wonderfully prolific Cucumber. Mr. A. Pettigrew, Cardiff Castle, obtained it from a cross between *Telegraph* and *Hedsor Winter Prolific*, the latter a small and very handsome variety sent out many years ago from the Royal Nursery, Slough. While of good length, Cardiff Castle is very handsome. A brace of highly-developed fruits would take a good deal of beating on the exhibition table.—R. D.

**Spinach for late spring.**—Those who have had failures with Spinach sown in the ordinary way, that is in July or August, would do well to sow now. Though there is no produce during the winter, there will be a grand supply in March and later when green vegetables are scarce. Spinach sown late does not get killed by frost, and though slugs may be troublesome they are readily got rid of by dusting the plants with lime, foot, and dry wood ashes in equal proportions. In light soil I find it advisable to roll the soil both before and after sowing. Sow thinly and do not thin till early spring, when the plants may be cut out for use as soon as large enough. From this late sowing during the past four winters I have never been without a good supply of Spinach at a season it is required. There is no need to sow on sheltered borders. The best variety for this purpose I have found to be the Round-leaved *Victoria* or *Viroflay*, which produces very fine leaves in the spring and does not run till well into May, when spring-sown Spinach will be producing freely.—S. H.

**A good Cucumber.**—I recently saw a very fine lot of *Rochford's Market Cucumber*, a variety not much grown in private gardens. This variety is likely to become a standard kind, as the quality is so good. This combined with its wonderful cropping will place it in the front rank. It is not a large, coarse kind, but of a useful size, the fruit rich green with prominent spines. It is somewhat like *Telegraph*, but even more prolific than that well-known kind. Last winter I tried it for winter forcing by the side of several well-known kinds, and was highly pleased with it. As a market variety it needs no commendation, its value being well known.—G. W. S.

**Savoy Earliest of All.**—This is a valuable addition where early Savoys are required, as the produce is particularly delicate and tender when cooked. The variety named is a very compact grower, the heads being conical, the lower leaves resting on the soil. It is a very good vegetable to follow early or midseason Potatoes. I grew it this season, and am so pleased with it, that in future I intend to grow it more largely, doing away with the *Green Curled*. For gardens of limited space where vegetables in quantity and of good quality are required this *Savoy* will be found valuable.—S. M.

**Yellow Turnips in winter.**—These are not much grown in the southern parts of the kingdom, but when there is a great scarcity of vegetables, such as was experienced last March and

April, the yellow-fleshed Turnips sown late will give a supply of good sweet roots. For standing the winter I consider the yellow Turnips invaluable, as if not required for their roots the tops give a wealth of greens at a season green vegetables are none too plentiful. These kinds are specially adapted for heavy clay soils or exposed positions. Among the few Turnips that withstood the severe frost last winter were the Petrowski, or Yellow Finland, Golden Ball, and Orange Jelly. The first named is flatter, and I do not think equals the Golden Ball in quality, but is specially good for sowing for winter greens, using the roots of the last named for storing or table use. It is surprising what severe weather yellow Turnips will stand without being injured. As regards flavour in the winter they are a long way before the white section, being solid when the white kinds are soft, pithy, and flavourless. For some years I depended upon Orange Jelly for the supplies from January to April. Of late I have grown Golden Ball, a very handsome root

being very free cropping and of superior quality, coming into bearing in a shorter time than the older varieties, this making it specially valuable. The pods, long, straight, of fair breadth, and very fleshy, are rich green, resembling in appearance those of some of the best types of dwarf Beans.—S. H. B.

**Pickling Cabbage.**—Dwarf Blood Red is of very compact growth, very solid, and of remarkably quick growth, colour deep blood-red. The value of this variety is that the plants from spring sowings are superior in colour to those requiring a longer time to grow. Sown in March and planted out in good land early in May there will be fine heads by the early autumn. There is less coarse rib or white portion of stalk in this variety, so that there is a greater portion fit for use. The colour when prepared is all one can desire.—G. WYTHES.

**A record weight in Onions.**—On the occasion of Mr. Henry Deverill's recent Onion show

fluence of a very erratic season, not only have very much grown out, but also become very ungainly. Indeed, I have rarely seen the larger tubers more so. In a season when any quantity of fairly good varieties can be purchased at so low a price as 50s. per ton, it is very clear that a crop much composed of these ungainly tubers must be sold at even a lower price than that, say 1s. per bushel, and that is far below a paying price for other than a wonderful crop. I feel that we have too many of this long type of Potato and that it is time raisers gave them up as breeders, keeping more to the rounder section of varieties, as these have all showed good character and have turned out, so far as I have seen of some seventy varieties in diverse soils, an excellent sample. We have occasional seasons when the long-tubered varieties are of very good form, but they are seasons when growth is constant from beginning to end. Both this season and in 1893 we had weather that gave severe checks to Potatoes, and the ungainliness now so common was then seen also. Beyond this ugliness there is, consequent upon the second growth or elongation which ensues when rains follow after a long spell of drought in the summer, much undue size which is at once objectionable. Then where second growth ensues, the first grown portion of the tubers is essentially different from that of the later growth, and cooking is in such case very unsatisfactory.—A. D.

## TREES AND SHRUBS.

### DAPHNIPHYLLUMS.

ALTHOUGH this genus has for some years been represented in a few gardens and nurseries, the fact that mention of it is altogether omitted in even the latest and most popular horticultural dictionaries is sufficient evidence of how little the Daphniphyllums are known in gardens generally. There are, however, besides more tropical species, at least two which may be included amongst the most valuable of hardy evergreens. The genus comprises some twelve or fifteen species, natives for the most part of Asia, their distribution on that continent extending from China, Japan and the Himalayas in the north, to Java and other Malayan islands in the south. One species—*D. africanum*—is found in West Tropical Africa, where it was discovered by Gustav Mann in 1862. They are all evergreen shrubs or trees belonging to the Euphorbia family, and the flowers of none of them have any pretensions to beauty. The same character of leaf runs through the genus—large and firm in texture, one Malayan species (*D. laurinum*) having them 1 foot long and 4½ inches wide.

*D. GLAUDESCENS* (the species represented in the engraving) is the best known of all the Daphniphyllums in cultivation. It is widely spread over Northern Asia, and although all the plants in this country have in all probability been brought from Japan, it exists also in a wild state in China, Corea, Hong Kong, &c. Richard Oldham, the Kew collector, saw it in Japan growing to a height of 30 feet, but in this country it has not yet got beyond a shrubby state. The largest specimens are from 6 feet to 8 feet high and form spreading, rounded bushes, wider than they are high. The leaves, each 4 inches to 8 inches long, are of lanceolate shape, pointed, and of a dark green colour above, paler beneath, and more or less glaucous. There appear to be two varieties in cultivation, one of which has the petioles and young wood of a red colour, whilst in the other they are green. The flowers, borne on short axillary racemes in the autumn, are small and inconspicuous; the fruit is black and about the size of a large Pea. Messrs. Veitch obtained a first-class certificate for this shrub in June, 1888.

*D. JEZOENSE.*—This name does not appear in the "Index Kewensis," but it has been given to

*Daphniphyllum glaucescens.* From a photograph by Lord Annesley.

similar to the Snowball as regards shape and quick growth, and really a delicious winter vegetable. To get good roots and a long supply I usually make two sowings, one in August, another in September, the former for the midwinter supply, the latter for greens or late roots to last till the new roots are fit for use. In storing give as cool a place as possible, choosing medium-sized roots not larger than a cricket ball.—G. WYTHES.

**Potato Boston Q. Q.**—I cannot agree with the remarks of "W. S." ament this Potato. Having given it a good trial, I am compelled to abandon it, owing to its ugly deep eyes and, moreover, its bad cooking quality in our soil, which is not favourable for some kinds of Potatoes, being heavy and somewhat retentive of moisture.—E. M.

**Runner Bean Prize-winner.**—At the recent show held in the Royal Horticultural Society's Gardens at Chiswick I noted most of the leading collections of vegetables contained the above variety. It is a distinct advance on older kinds,

at Banbury, Mr. J. Bowerman, The Gardens, Hackwood Park, Basingstoke, won the gold medal with six bulbs of Ailsa Craig Onion weighing 17½ lbs. The heaviest of the six weighed 3 lbs. 1 oz., and the next largest was only half an ounce lighter. Mr. Bowerman said that when lifted the largest weighed 3 lbs. 6 oz., but it had lost 5 oz. in drying off. The six Onions were almost perfect specimens of high-class cultivation, very solid and weighty, and admirably finished. Ailsa Craig is a very handsome Onion, of globular shape with pale greenish straw-coloured skin. Of the flat Onions, Anglo-Spanish is the finest, twelve very finely finished bulbs from Mr. N. Kneller, Malshanger Park, Basingstoke, weighing 21½ lbs. Time was when it was thought to be a great feat in Onion-growing to have twelve Banbury Onions weighing 15 lbs.—R. D.

**Long round Potatoes.**—In lifting both these descriptions of Potatoes this year I have not been surprised to find that many of the long or commonly called kidney forms, under the in-

a plant which is dwarfer than the preceding. The only species native of the island of Yezo (Japan) is *D. humile*, which was first discovered in 1861, and again by Mr. Maries nearly twenty years later. This is probably the plant now grown in England as *D. jezoense*. It is quite distinct from *D. glaucescens*, being a much dwarfer plant and having leaves 2 inches to 3 inches long and proportionately broader than those of the larger species; they are vividly glaucous beneath. Professor Sargent says that *D. humile* is a common undershrub in the forests of deciduous trees in Yezo. A plant grown as *D. jezoense* at Kew is 4 feet 6 inches through and 18 inches high. The species will prove useful in positions where evergreen shrubs that will keep dwarf without the severe pruning that Laurels and Rhododendrons need are required.

Both these plants are quite hurdy in the neighbourhood of London when once they have become fairly established. When young, however, they are liable to be cut back by hard frosts, especially when they are not protected by snow. A little protection should therefore be given for the first few seasons. Bracken or Fir branches laid over them are as good as anything. When they get older and more woody they seem quite impervious to frost except where here and there a late autumn growth has its succulent unripened wood destroyed. They will thrive in any fairly rich garden soil that is not too heavy and wet. Both these species are likely to remain rare for some time unless a large importation of good seed can be obtained. I have propagated them from cuttings put in about July or August, but they are slow and uncertain in rooting. Layering probably would prove a surer method. W. J. B.

**The Mountain Ash.**—What a glorious display this berry-bearing tree is making this autumn. It matters not what county one travels through, the brilliant berries of the Mountain Ash meet his eye. This tree ought to be used more freely in pleasure-ground planting, for, independent of its beauty in autumn, its general character is highly ornamental. Unfortunately, in dry seasons like the present the brilliant berries soon fall a prey to birds. Amongst country folk a rich display of Mountain Ash berries fosters the belief that there is a hard winter in view. Personally, however, I do not attach any weight to this idea, as generally by November every berry is gone. I have sometimes wondered if there were several varieties of this Ash, as on some trees the berries when ripe have a much darker, richer colour, but this is perhaps due to soil and situation.—J. C.

## FRUIT AND VEGETABLE CROPS.

### SCOTLAND.

**Brahan Castle, Dingwall, Ross.**—Fruit crops are very good all round this quarter this year, but the dry weather did not affect us here in Ross. Apples very good. Pears above average. Plums heavy crop. Apricots good average, and all small fruits very good. The great drawback with orchard Plums in the north is the autumn frosts, which completely spoil them just when ripening. Jefferson I find both for appearance and flavour is the best dessert Plum, and Victoria for kitchen use.—Geo. SIMPSON.

**Ardoe House, Aberdeen.**—The fruit crops in this district have been good. Early Strawberries were rather small owing to the continued dry weather; later ones are a heavy crop, also Gooseberries, Currants and Raspberries. Apples are thin. Plums a fair crop. Cherries good. Peaches are a good crop on walls with a little protection, but not much grown in this district. The crops all suffered very much in the early part

of the season, but since the rain came vegetation has improved greatly and crops are turning out well.

Potatoes are an excellent crop and of fine quality; no appearance of disease. Early Cauliflowers have been a failure all round here with canker. The past winter was a very severe one, many things being killed outright. Shrubs have suffered the most. Common Laurels have been killed to the ground. Barberries, Cedars, &c., have all suffered more or less. Roses on walls were sadly destroyed, but those in beds did not suffer so much owing to their being covered with a good depth of snow during the hard weather.—JOHN HAY.

**Drumlanrig Gardens.**—All small fruits such as Currants, Gooseberries and Raspberries are in great abundance and fine in quality. Strawberries, owing to the drought in the early part of the season, were smaller than usual, but of fine quality. Plums, Cherries and Apples are plentiful.

Potatoes (as they always are in dry, warm summers) are healthy and good. Most vegetable crops, owing to the dry weather, were checked and retarded, but with the recent heavy rains they are now making rapid progress.—D. THOMSON.

**Brechin Castle, Forfar.**—The fruit crops here are very fair taken as a whole. Apples are an average crop, but Pears are under the average. Plums are not a heavy crop; those bearing best are Victoria, Kirke's, Rivers' Early and Orleans. Cherries are a fair crop and small fruit of all kinds plentiful. Strawberries have done well, the rain just coming in time to save the crop. Wasps are quite a pest this season, attacking all ripe fruits.

Vegetables have mostly done very well. Early Peas were very good, but later sowings are not promising so well, filling slowly with this wet weather. Early Cauliflowers buttoned a good deal during the drought, but later sorts are doing well. The maggot has been very bad on Onions this season, but Carrots, on the other hand, are very healthy. Potatoes are an excellent crop, although the quality is not first-rate. Disease has not begun to show yet.—W. McDOWALL.

**Carberry Tower, Musselburgh.**—The fruit crops in this district with a few exceptions are this season very good. Apples and Pears rather thin, although the trees looked well when in bloom. Plums fair generally, Victoria extra fine. Cherries, both Morello and sweet, enormous crops. Strawberries were a good crop, the fruit fine and of good flavour, and lasting longer than usual. Gooseberries, Red and Black Currants very plentiful. Raspberries scarce, having suffered much from severe frost last winter.—D. KIDD.

**Dochfour Gardens.**—All small fruits, Strawberries, Raspberries, Currants, Gooseberries, &c., excellent crops, but inferior in flavour. Apples, Pears, Plums and Cherries only about one-fourth of general crop. Wall fruit thin, but of good quality and large size.

Vegetables splendid crops, especially Peas, Potatoes, Cauliflowers, Beans and indeed all green crops.—R. STEWART.

**Arbuthnot, Fordoun, N.B.**—The small fruits here, including Strawberries, Raspberries, Gooseberries, and Currants of all kinds, have been an extra heavy crop, also of extra size and quality—in fact I have never seen a heavier crop nor larger fruit of Currants. Apples on standards a failure, only a very few here and there. Pears on walls I never saw worse; as standards, Pears do not do here at all. An average crop of Apples on wall trees.

Potatoes are a very good crop, of large size and of excellent quality. Peas have done remarkably well this season. Potatoes and Peas seem to have enjoyed the very dry and hot weather we had in May and June. We have had abundance of rain now.—J. M. GAINES.

**Eyvie Castle, Eyvie.**—We had a very severe winter, and during the month of January we registered 51.9° of frost: the mercury came down to 8° be-

low zero on the 9th, 11th, and 25th of the month, and during the twenty eight days in February we registered 59.8° and coming down to 18° below zero, or 50° of frost, on the 11th and 13th of the month, which did enormous damage to the fruit trees and shrubs. The majority of the fruit-buds got nipped, and the crop this year is but very light. Small fruit, such as Currants, Gooseberries, and Strawberries, are a good average.

Potato crops are good and very promising.—SIMON CAMPBELL.

**Broxmouth Park, Dunbar.**—We have a heavy crop of all sorts of fruit this year, assisted no doubt by the scarcity of last season. Our most reliable kinds of Apples, and which are bearing well, are Keswick Codlin, Lord Suffield, Stirling Castle, Warner's King, Hawthornden, Golden Spire, Ringer, Golden Noble, Blenheim Orange, Cox's Orange, King of Pippins, Worcester Pearmain. Pears are an average crop, also Apricots, although not equal to last year. Plums are good on young trees on walls of Victoria, Jefferson, Kirke's, and Green Gage, and I believe from orchards Victoria might be grown in this locality to some advantage. Morello Cherries are looking well and are a nice crop. Small fruits are in great abundance. Strawberries suffered for a time from the want of rain. Raspberries are plentiful and fine, and extra large upon Superlative. Gooseberries are breaking down the bushes. Red and White Currants are very fine, but Black Currants are not so large as usual.—WM. MCKELVIE.

### WALES.

**Cardiff Castle.**—The past severe winter damaged a great many trees and shrubs in this district. In the pleasure grounds here dozens of large Cupressus macrocarpa from 50 feet to 70 feet high were all killed by the severity of the frost, and the younger trees of the same species suffered equally; not a single plant in the most favourable position escaped. Several of the finer varieties of conifers which were previously considered hardy succumbed to the cold blast. Some of the Vines trained on the castle wall here—twenty six years old and 40 feet high—were killed to within a few feet of the ground, while those in the open vineyards were not injured in the least. The Raspberry canes growing in open quarters in the garden here were killed to the ground. Tea and other Roses were badly injured, and in some cases killed outright. Vegetables of all kinds were badly cut up and the Broccoli all destroyed, with the exception of Veitch's Model. The small rainfall of the present year (11.84 inches to the end of June) and the long-continued drought in May and June were very trying to vegetable and fruit crops of all kinds, but since the heavy rainfall in July they have improved wonderfully. The fruit crops, more especially Apples and Pears, are the best we have had for several years. The weather proved favourable for them during the flowering season and almost every bloom set, but owing to the enormous set and the long-continued drought that followed, a great many dropped after they had grown to the size of pigeon's eggs, much to the relief of the over-burdened trees. Of Apples, the following varieties have had to be propped up to keep the branches from being broken down under the great weight of fruit: Lord Suffield, Lord Grosvenor, Cox's Orange Pippin, Ecklinville, Worcestershire Pearmain, Peasgood's Nonsuch, Alfriston, Gloria Mundi, Irish Peach, and several others. Wellington, Blenheim Orange, Lane's Prince Albert, and, indeed, most of the varieties here are bearing excellent crops of fine clean fruit. The crops of Pears, both on wall and pyramidal trees, are exceptionally good, and the following varieties, trained as pyramids in the open quarters of the garden, have had to be propped up with long Larch poles and roped all round to save them from being broken down: Pitmastou Duchess, Jargonelle, Williams' Bon Chrétien, Vicar of Winkfield, Baurré Base, Baurré d'Amanli, Baurré Diel, Marie Louise, Thompson's and many others. Of

Plums growing in the open trees is an average crop. The best are on bush trees of Victoria, Kirke's, Bryanston Gage, Coe's Golden Drop, and Transparent Gage.—A. PETTIGREW.

**The Hendre, Monmouth.**—With the exception of Apricots, all kinds of fruit trees blossomed freely this season. Pears and Plums, however, received injury from frost, and it was noticeable that the trees on east walls, and consequently exposed to the sun's influence early in the morning, suffered most. In ordinary orchards Apples and Pears are plentiful, although the crops are partial. In our fruit garden, which was planted with pyramid trees in Nov., 1893, the crops are good. Of Apples the best are Baumann's Red Reinette, Cellini, Frogmore Prolific, Gascoigne's Seedling, Grenadier, Lane's Prince Albert, Seaton House, Sandringham, Schoolmaster, The Queen, Tyler's Kernel, Warner's King, Brownlee's Russet, Cox's Orange Pippin, King of the Pippins, and Worcester Pearmain; of Pears, Catillac, Conseiller de la Cour, Doyenné du Comice, Durondeau, Louise Bonne of Jersey, Pitmaston Duchess, Souvenir du Congrès, and Beurré Fouquieray. Of Cherries, May Duke, Late Duke, and Morello; and of Plums, Coe's Golden Drop, Transparent Gage, Jefferson, Kirke's and Victoria are all very good. Strawberries, Raspberries, Gooseberries, and Currants are excellent in every way; the crops abundant and individual fruits remarkably fine. The winter moth has been troublesome in some orchards where no means were adopted to check it; black fly had to be kept under upon Cherries; caterpillar upon Gooseberries, and honeydew upon Currants. Plums have, however, remained perfectly clean. The late rain has caused an increase in the size of Apples and Pears, and improved the appearance of the foliage of all fruit trees. No injury to fruit trees accruing from the late severe winter has been observed. Apricot trees are in perfect health, as are young Peach trees which were planted last autumn.—THOMAS COOMBER.

**Crosswood Park, Cardigan.**—The fruit crop in this neighbourhood is above the average, especially Apples. The trees are loaded everywhere. Currants and Gooseberries were very plentiful, also Raspberries. Strawberries suffered very much from the long-continued drought; although they had a splendid show of blossom, it did not come to perfection and the crop was a short one, although the flavour was very good. Pears do not appear to have suffered from the hard winter; they are carrying a good crop. They began to drop with the drought, but since the plentiful rains they have improved wonderfully. The Apples had begun to drop before the rain, but are now swelling fast and will be a very heavy crop. Cherries were much above the average, especially on the walls, and of excellent flavour. Peaches and Nectarines are about an average, but the flavour is never very good in this district. Apricots are below the average, and seem to have suffered most from the hard winter, very little blossom showing. Plums are a heavy crop both in the open and on the walls.—R. C. WILLIAMS.

**Picton Castle, Haverfordwest.**—The fruit and vegetable crops in this neighbourhood are amongst the best we have had for some years, in spite of the severe winter and the dry season we have had. Fruits crops generally have been and are good, particularly Apples, Cherries, Peaches, Nectarines and small fruits, the only exception being Raspberries, the canes of which were injured by the severe winter. Strawberries were a most abundant crop and particularly good. Pears are slightly under average, as also are Plums, which are not grown very extensively in this neighbourhood.

Vegetable crops are also very satisfactory in our heavy deep soil, the dry season having been rather favourable than otherwise. Potatoes are yielding a very heavy crop and no disease has appeared. Onions and Peas are also good.—J. DUMBLE.

**Mostyn Hall, Mostyn.**—We have had fine crops here. Plums are an exceptionally fine

crop. All wall trees are cleaner here than I have seen them for the past few years, which, I think, is due greatly to not getting such easterly winds in the spring as we generally do. A great deal of fruit was beginning to fall through the drought, and perhaps it is as well it did. The rains we have had recently have greatly helped the fruit, and I expect Apples, Pears and Plums will be very fine.—J. BARNARD.

**Llannerch Park, St. Asaph.**—The fruit season here this year is exceptionally good, Strawberries especially. Apples are good. Pears not so plentiful as last year. All bush and stone fruit above the average. The past winter killed several plants and shrubs that have not been hurt before. A dry, hot summer suits fruit trees here well, as the soil is very stiff with a clay bottom.—J. YOUNG.

**Penrhos Gardens, Holyhead.**—Anglesey is not a fruit-growing county, but in various parts where shelter is obtained very good crops of fruit are produced. Apples this year are much above the average. The most abundant bearers are Beauty of Bath, Ecklinville, Lord Suffield, Warner's King, Duchess of Oldenburg, Devonshire Quarrenden, Sturmer Pippin, Peasgood's Non-such, Dutch Mignonne, Worcester Pearmain, Lane's Prince Albert, Bramley's Seedling and Frogmore Prolific. Pears are under the average except some of the most prolific kinds such as Beurré Giffard, Souvenir du Congrès, Beurré d'Amanlis, Marie Louise, Doyenné du Comice and Winter Nellis. Cherries a very good crop, especially Morellos. Strawberries produced very good crops and fine; these were mulched early and withstood the drought remarkably well. Gooseberries, Raspberries and Currants are abundant. The Plum crop here on walls is much under the average. The two first to ripen are Early Prolific and The Czar. Kirke's, Jefferson and also Victoria are bearing very fair crops. Victoria is the most certain bearer.—F. W. EVERETT.

**Vaynor Park, Montgomeryshire.**—The fruit crop here is a very good one, more especially Plums, Apricots, Peaches and Nectarines. These are plentiful and promise to be excellent in quality. Cherries and Strawberries are a most abundant crop. Raspberries are a fair average crop. Gooseberries and Currants are a good average crop. Pears are below the average. Apples are plentiful, but fruit small. The Walnut trees are bearing heavy crops. Filberts and Nuts are thin. I find all kinds of Plums do well here. Some of the trees were planted about seventy years ago. I have known them fifty years, and I may say if there are Plums anywhere, there is always plenty here.—R. H. SMITH.

**Glanfôn Gardens, Taibach.**—The Apple crops without exception are unusually good. Pears, both on standards and walls, are very fine and good. Indoors the yield from Peaches and Nectarines has been very heavy, the fruit being remarkably fine and well flavoured. The outdoor trees are heavily laden, while the trees are healthy where water could be supplied to them during the drought experienced in the early part of the season. Plums are not grown as standards or pyramids in this district, but the wall trees bear very heavy crops. The Cherry crops on walls and standards are very good. Currants were unusually fine, while the bushes were remarkably clean and healthy. The Strawberry crop was excellent, surpassing the yield of any previous year. The fruit was exceptionally fine. Laxton's Noble and Vicomtesse Héricart de Thury stood the drought well, and were among my best. The Gooseberry trees suffered badly from the severe winter, and the crop was quite a failure.—HENRY MORRIS.

**The Gardens, Slebech Park, Haverfordwest.**—Apples are a most abundant crop, all varieties alike; the fruit is clean and of a good size. The weather during the blooming period was dry. Pears are a very thin crop. We have had very heavy crops the past two seasons, and the trees appear to be to a certain extent exhausted. Josephine de Malines I find to be the most continuous bearing variety in this district.

We have also on some of the trees fair crops of Marie Louise. Cherries were a very good crop, especially the Morello. The Cherry is not much grown in this district, as it seldom succeeds. Peaches and Nectarines are almost unknown as outdoor fruit in this district; only an isolated tree here and there partially succeeds. Apricots the same; nobody plants them outdoors, but, like Peaches, good crops of them are produced under glass in this county. Small fruits were a very good crop with the exception of Gooseberries, which were in many gardens almost a failure. Strawberries a splendid crop of good clean fruit, but seen over owing to the drought.—GEO. GRIFFIN.

**Bodnant Gardens, Eglwysbach, Denbighshire.**—I am pleased to be able to report most favourably on the fruit crops in this neighbourhood. Apples are an excellent crop; I have had to thin them considerably. The same may be said of Plums, with the exception of a small black variety, which is grown rather extensively in this district. Pears on walls and sheltered positions are a fair crop; others not so favoured are very poor. Apricots a moderate crop. Peaches and Nectarines I do not grow in the open air, but within a few miles (on the coast) they are grown with success, and are this season bearing well. Morello Cherries very good. Strawberries set well and early pickings were very fine, but later gatherings were small owing to the drought. Gooseberries, Currants, and Raspberries all bore excellent crops of fine fruit. Walnuts and Filberts are rather light. The crops with the exception of Strawberries do not appear to have suffered from the drought in May and June.—J. SAUNDERSON.

#### IRELAND.

**Fota Island.**—The fruit crop in this neighbourhood is quite up to the average. Strawberries, Gooseberries and Currants abundant, but in consequence of the drought in the early part of summer the Strawberry season was a short one; many plants died from the want of rain. The popular variety of this county (M. MacMahon) suffered most. Apples abundant, but fruit rather smaller than usual in consequence of heavy crop. Cox's Orange Pippin, Kerry Pippin, Mr. Gladstone, Blenheim Orange (the first season we have had a crop of the last named for twenty years), Bramley's Seedling, Bismarck, Lord Grosvenor, Tom Putt, Lane's Prince Albert, Loddington Seedling, Tower of Glamis, The Queen (very fine), Warner's King, Annie Elizabeth, and Small's Admirable are amongst our best. Pears an average crop, but all early kinds poor in quality; Marie Louise, Glou Moreau, Beurré Diel, and Beurré d'Amanlis small. After the spell of dry, tropical weather in June, two months of cold, sunless, wet weather followed, which caused the Pears to crack and spot. Apricots failed to ripen. Peaches and Nectarines heavy crop of fine fruit, but lacking in sugar. Plums a good crop; many rotted unripe on the trees. Morello Cherries an excellent crop.—W. O.

**Glenstal, Limerick.**—The present year will be remembered as a year of plenty in these gardens. Fruit with but few exceptions is considerably above the average. Taking them in the order of ripening, Strawberries were an enormous crop, the berries exceptionally large, and, thanks to the glorious sunshine, of which we seldom get a fair share, the flavour was first-class. Black, Red, and White Currants were a very heavy crop. It would appear, however, that a moist season suits the Black varieties, but as the berries were smaller than usual, and, moreover, ripened prematurely, the drought did not affect the Red and White varieties. The same may be said of Raspberries, which were and still are good, while the canes made this season are remarkably fine. Gooseberries are without doubt the heaviest crop I have ever seen; they, however, are a light crop throughout the district generally. Pears on walls are a first-rate crop, but pyramid trees have a light crop with the exception of Williams' Bon

Chrétien, which is always a certain cropper here as a pyramid. All young Apple trees are heavily laden with very fine samples of fruit. Some old standard trees cast a good many fruit a few weeks since, but there is still a good crop left. I have recently visited several gardens in Limerick, Clare, Tipperary, and the same remarks are applicable in all cases, save in that of Apples on standard trees: these are all bearing heavy crops everywhere. I have never, however, seen a heavier crop of good Apples than I saw in a large orchard at Dolla, Nenagh, Co. Tipperary: the trees were both large and old. Apricots and Figs are very light crops. Peaches, on the contrary, are carrying very heavy crops; the fruits, too, individually are larger than usual. Plums are a very light crop on standard trees; in fact, they are never good under that system of culture. Victoria on walls is annually a certain cropper; though only second-rate in flavour, it is a most useful cooking Plum. Green Gage and Magnum Bonum are very lightly cropped; in fact, no Plum I have tried in our mossy soil is satisfactory but the Victoria. I do not consider this a good soil for Plums owing to a deficiency of lime in the soil, that being most essential to ensure success during the stoning period. I have not tried any of the new Plums owing to the unsatisfactory results from the old varieties. Morello Cherries were a very good crop, but the sweet varieties were a poor crop. Taken all round, it will be seen the fruit crop is a good one. Nuts, I may add, are slightly under average. The result of the past severe winter is in every way satisfactory, while the drought has done but little harm in gardens.

Onions are a very fine crop; so are Peas, French and Runner Beans. Turnips are excellent on north border, but Spinach has bolted very quickly during the wet weather. Beetroot came up indifferently during the dry weather; there is, however, sufficient for a crop, and it is doing well now. Some of the early Celery, though regularly watered, has bolted; the main crop is most promising; the same may be said of winter greens, &c. Potatoes, the staple crop of Ireland, are an excellent crop, and, what is of greater importance, of first-rate quality; in fact, some could not possibly be beaten, notably old Ashleaf, Cottage's Red, and Reading Ruby.—R. WELLS.

**Clontarf Castle, Co. Dublin.**—The fruit crop here is most abundant, and I may say the same for all this district. Apples, Pears, Plums and all small fruits, particularly Raspberries, often a doubtful crop here, are good. The fruit will hardly be so large as two years ago, but if we get a few weeks of hot sun to finish it off for keeping, we will in this district have no reason to complain of the crop of this year.—J. DORAN.

**Grantstown, Tipperary.**—The Plum trees are laden with very fine fruit. The Apples are very satisfactory here and in surrounding gardens. If the fine weather we are having continues, the flavour and keeping properties will be greatly improved. Pears are fairly plentiful; Williams' Bon Chrétien is rather light. Peaches are excellent and remarkable for their good flavour and high colour; Cherries good and well flavoured. The bush fruit on the whole is very good.

Vegetables are very fair with the exception of Peas, which were very poor.—H. KELLY.

**Castle Bellingham, Louth.**—The fruit this year in this locality is only a medium crop. Black Currants not up to usual average; the same may be said of Pear and Apple crops. I believe that the heavy frosts at the time these were in bloom had much to do in producing the above results. We do not grow any of the new kinds of Plums about here, but I am sure that a more extensive cultivation of the Plum in this country would greatly add to the value of garden produce. The soil in this neighbourhood is a gravelly loam, and, except in very dry seasons, fruit trees of all kinds do very well. Even in ordinarily dry seasons I find it difficult to obtain good crops of Strawberries. This year I paid particular attention to watering the beds, and so obtained a good crop.

Potatoes appear to be everywhere an abundant crop and of good size, and no disease so far. They are excellent in this garden, but I have heard complaints in other directions of them being more soapy than they have been for some years.—E. DORMAN.

**Mitchelston Castle, Cork.**—Small fruit was much above average both in quantity and quality. Strawberries were exceptionally fine. Pears and Apples are over average. Plums also are very fine, though a little deficient in flavour on account of so much rain. A dry or moderately dry summer is best suited for fruit here, as the soil generally is a deep retentive loam on the blue limestone. In a wet season Pears and Plums crack and the flavour of all fruit is deficient.—R. WILSON.

**Antrim Castle, Antrim.**—Apples, Pears, Plums and Cherries are all very good here. The Plum crop is also good. Gooseberries, Raspberries, Red and Black Currants and Strawberries have all been good; the last rather small, owing no doubt to the very dry time after the fruit was set. Grapes, Peaches, Nectarines, Melons, Cucumbers, Tomatoes, &c., inside are all good.

Vegetable crops on the whole are looking remarkably well, with the exception of Potatoes, which were all cut down to the ground by the frost on June 13; consequently the crop is not so good as it probably would otherwise have been. I have seen no disease yet.—FRANCIS ALLEN.

**Castlewellan.**—Apples, Cherries and Plums are under the average. Small fruits very abundant. Gooseberries, Currants and Raspberries very fine. Strawberries plentiful, but small; owing to the long drought they were soon over. The following varieties of Pears on south and west walls are over the average and the fruit very fine: Pitmaston Duchess, Marie Louise, Emile d'Heyst, Fertility, Gansel's Bergamot, Jargonelle, Louise Bonne of Jersey, Magnate, Autumn Bergamot, Beurré Capiaumont, Beurré Giffard, Beurré Superfin, Clapp's Favourite, Conseiller de la Cour, Marie Benoist, Doyenné du Comice, Duchesse d'Angoulême, Williams' Bon Chrétien, Beurré Bachelier, Beurré d'Amanlis and Beurré d'Arenberg.—THOS. RYAN.

**Bossborough, Kilkenny.**—We have a very fine crop of Apples, the best for some years, and all the orchards around us have splendid crops. The fruit is of a very good colour, thanks to the fine weather. Pears a very light crop. Peaches under glass very good. Morello Cherries a very fine crop. Currants, both Black and Red, and Raspberries very fine crops. Gooseberries extra good, Whinham's Industry and Warrington being the best.—WILLIAM CLARKE.

**Curraghmore, Co. Waterford.**—Taking everything into consideration, our fruit and vegetable crops this year are very good. We did not suffer much from last winter; only once the thermometer registered 28° of frost, and fortunately we had a downfall of snow the day before. The dry spring kept everything back. We also had a few late frosts, but not so bad as in Scotland and England, our last being May 22 and only 2°—Apples not being forward enough. We have a very heavy crop, Keswick, Hollandbury and Annie Elizabeth being our best crops, whilst Ribston, Cox's Orange and Hawthornden are very good. Pears are fair. Plums average. Peaches very good inside and out. Apricots poor. Cherries average. Small fruits were extra good. Strawberries I never had better in flavour, size and quantity.—THOS. SINGLETON.

**Belvedere House, Mullingar, Westmeath.**—The first two months of this year will long be remembered for the severity of the weather and the amount of damage done to trees, shrubs, and vegetables; even the Furze, Laurel, and evergreen Oak suffered severely, and in a damp situation one large tree of the last was killed. A fine specimen *Chamaerops humilis*, 17 feet high, which I was afraid had been killed, I am glad to say is growing strongly from the crown. Its roots were protected by Bracken. Tender shrubs planted in a western aspect suffered much less than in any other position. All the

Brassica family suffered severely. Of Broccoli, Dickson's Late May, Veitch's Model, and Leamington suffered the least. The Victoria Improved Round Spinach also stood well. We registered 27° of frost on the night of February 5, 2 feet from the ground. Considering the very dry spring, crops are doing very well, the rains coming in time to swell up the fruits, and the trees are making good growth; altogether the fruit crop is over the average, excepting the Pear, which is almost a failure.

Early Potatoes turned out well and of good quality; late ones look very promising and there are no signs of disease.—JAMES BAYLISS.

## GARDEN FLORA.

### PLATE 1034.

#### CYMBIDIUM EBURNEO-LOWIANUM.

(WITH A COLOURED PLATE.\*)

No hybrid Orchid of recent years has created so great an amount of interest as this charming variety. It is in every way distinct from both of its parents, yet has a certain amount of resemblance to each. Taking into consideration the two noble species to which it owes its origin, it would indeed be a surprise if the offspring were not itself also of equal excellence. As *Cymbidium eburneo-Lowianum* becomes more plentiful it will most assuredly be greatly sought after by Orchid lovers who are in search of the best kinds in each respective genus. A goodly number of plants has already been distributed, and no inconsiderable quantity has flowered with the raisers, Messrs J. Veitch and Sons, at Chelsea. When first described in 1889, the year in which a first-class certificate was awarded to it as a new and noteworthy plant, the spike from which the description was written bore three flowers, but it was then predicted that with greater strength there would be an increase. This has proved to be a fact, for this spring six flowers in one instance were counted, whilst in several cases the spikes have borne as many as five. There has also been an advance in point of size, as I have noted several on the plants exhibited of late that were much larger than those of either of the parents. This was especially so in the case of the fine plant in the possession of Mr. F. Hardy (see *THE GARDEN* for March 16 last, p. 190), which was specially noted at the time. I look to see a greater increase still in point of numbers, although it may not be possible to approach that of *C. Lowianum*, the seed parent of the hybrid in question. It is the finest hybrid *Cymbidium* yet raised, as well as one of the finest of all hybrid Orchids. The pseudobulbs and leaves are intermediate between those of the two parents (approaching more nearly in form and contour those of *C. Lowianum*), with the yellowish striations at the base of the latter characteristic of *C. Lowianum*. The racemes are longer than in *C. eburneo*, and bear from four to six or more flowers. The flowers have nearly the same shape as those of *C. Lowianum*, but are much larger. The sepals and petals are similar and sub-equal, light nankeen-yellow; the petals and lateral sepals spreading, the dorsal sepal bent forward; the lip is nearly, as in *C. Lowianum*, ivory white on the inner side, with a V-shaped red-crimson blotch on the reflexed front lobe, the lamellæ of the disc bright yellow. The column

\* Drawn by H. G. Moon for *THE GARDEN* in the garden of Baron Edmond de Rothschild, Armanvillers, near Paris, February 15, 1894. Lithographed and printed by Guillaume Severyna.

EPHEDRA MONSIEURII

is ivory white with some red spots at the base near the front.

By the courtesy of Mr. Veitch I was shown what in this instance is of especial interest, viz, the result of making *C. eburneum* the seed parent instead of *C. Lowianum*, as hitherto alluded to. The progeny resulting from this cross has approached more nearly to *C. eburneum*, inasmuch as there is a tendency to yield two flowers only to the spike, as in that species; there is also a slightly less amount of the nautic-yellow, whilst the inner part of the column is dotted with minute spots throughout; the foliage also is shorter, thus again inclining more towards the same species. The size of the flowers is, however, retained, as in the opposite cross, so also is the general outline. The treatment under which the parents thrive will also suit the offspring. The growth in both crosses is all that one could desire, that of the former being nearly as intermediate as possible, whilst in the latter it is somewhat shorter, the plants being of graceful habit. The disposition to either make back breaks or duplicates is also much in its favour. *C. eburneum*, it should be noted, was introduced fifty years ago from the East Indies (a wide range), whereas *C. Lowianum* comes from Burmah, having been sent over in 1877.

#### ORCHIS.

**Howth Castle, near Dublin.**—Howth Castle is one of the most beautiful places in Ireland, with its ancient garden containing unique Beech hedges of gigantic height, its Rhododendrons among the rocks and Brake Fern, and its magnificent views over the Irish Sea. The Gloire de Dijon Roses here are as big as tea saucers, and hedges of Lavender and Rosemary, Sweet Brier, and beds of Mignonette make the place as sweet as Rose gardens in Cashmere. To see the common Honey-suckle growing up the trees to a height of 50 feet or 60 feet here and wreathed with flowers is a sight rarely to be equalled, and the whole place is a paradise of wild flowers.

## THE WEEK'S WORK.

### FRUIT HOUSES.

**EARLY VINES IN POTS.**—These should now be in the open if required to force early, and any pruning required should be no longer delayed. The canes should be tied up to a fence or wall to get thoroughly matured, and as they require less moisture for a time till the leaves fall, it is well to protect from heavy rainfall. With such favourable weather as we are now experiencing, the Vines should not be allowed to suffer from the want of the necessary moisture. In securing to the wall it is well to take care that the canes do not get twisted by strong winds, as they soon suffer if the bark is injured. It is well to let the leaves drop off naturally, and if pruned as advised above, that is, the lateral growths cut back, the remaining leaves will soon fall. In standing the plants in exposed quarters it is well to protect the roots from full sunshine by partially plunging them, or placing boards or litter to shade them. When the Vines are introduced into their fruiting quarters, if hot water is the heating agency, a

good thickness of turf over bricks should be placed on the pipes, and as a strong heat at the start is not necessary, I have found fresh leaves one of the best materials for plunging. If manure alone supplies the heat, great care must be taken that it is a steady heat, and here again a liberal mixture of leaves with the manure will be beneficial. Young Vines need more heat at this season, so that 55° by night is none too high, allowing 10° higher by day and a free rise by sun heat, syringing several times daily to assist in breaking the buds. A genial bottom heat will likewise be necessary, but excess must be guarded against, and if a liberal portion of leaves is used, this being added to as required, there will be no fear of scorching the tender roots.

**EARLY PERMANENT VINES.**—In many gardens small houses of permanent Vines are now forced instead of pot Vines, and though the work advised above for pot plants is applicable here in certain details, it is necessary to vary the practice as regards ripening and exposure. Old Vines, if

Flower of *Cymbidium Lowianum*.

they have been forced regularly, are more readily ripened than young canes, and in no case do I advise pruning till the sap is flowing downward or when the growth has ceased. It may be necessary to shorten the growths, and by so doing time will be gained, as it allows more light to reach the canes and the final pruning may be done much earlier. It is a good plan to shorten lateral growths quite one half at this date, and terminal growths may be reduced likewise if well matured, as I find it checks bleeding by so doing. Vines required to produce ripe Grapes in April should have been prepared by shortening back, and must now be pruned to the required bud and prepared for the work, thoroughly cleansing the rods, as should insect pests have been troublesome now is the time to wage war against them and prevent future attacks. The rods should have the rough bark removed after pruning is complete. I do not advise scraping, which is sometimes practised. Merely remove useless or loose bark, and rely upon thorough cleansing by scrubbing the rods with a strong solution of soapy water, painting afterwards when dry. I am aware even this scrubbing and painting are not sufficient to remove mealy bug, but it will remove so many that it is an easy matter to get rid of any left if the Vines are carefully looked over daily when the bunches are forming and after thinning. I have seen so many Vines injured by applying strong solutions of paraffin and tar in large quantities, that it is well to rely upon milder methods. I admit tar in suitable proportions is very beneficial in destroying bug, and have used it to advantage. A good mixture for painting

Vines is sulphur, lime, and tobacco water, with a liberal portion of Gishurst compound mixed in tepid water, the whole to form a thick paint. This should be well rubbed into the bark, all crevices being stopped with the solution. After cleansing and painting, preparation must be made for starting. The surface soil if poor should be removed, new material, such as good loam with a liberal portion of bone-meal being added, and in the case of old Vines some fertiliser also given, previously removing the surface soil. It is well to see that the border is thoroughly moist, as with the favourable autumn weather we have experienced borders have got much drier than usual. Though the surface is moist it is well to soak thoroughly before starting the canes. At this season the roots may be given a good soaking with rain water from the tanks. Much the same routine is required as advised for early pot Vines. After closing the house for a short time it will well repay the cultivator to give warmth by covering the border with warm litter with which a liberal portion of fresh leaves has been mixed. I am aware the roots will be some time before they start at this season, but the warmth greatly assists the Vines to break freely, maintains a moist temperature, and saves much syringing. I do not advise forcing Vines for very early produce where the roots are outside. If possible it is well to force small houses, which can be better managed, as later on when the Vines require more warmth much may be done in severe weather by covering the glass on the outside to retain warmth.

**WORN-OUT VINES.**—Vines that have become unprofitable by overcropping, age, or other causes may be made to answer a double purpose if forced now, and thus provide early Grapes and make room for new Vines. Of course to force, say, early next month they should have been given a good rest if possible, but it cannot always be done, and the means at hand must be employed. Only a short rest may be given. In such cases prune back, and in doing this work it will be necessary to cut to the best bud, not pruning hard, as there is no need to study effect, the Vines being destroyed as soon as the crop is cleared. Every chance should be taken to get all the fruit possible, and of course it will not be necessary to clean the Vines so particularly as if they were permanent. If there is no bug or other pest, the barking and painting over may be omitted. A good dressing of Gishurst would be sufficient, and top-dressings may be given later on if necessary. These Vines will need a little extra heat at the start should the weather be dull and moist. Much may be done to forward the crop by placing manure on the surface, and in case of outside borders a liberal covering of manure and fresh leaves will be of great benefit. It is well to cover over freely after the warm material is placed on the border with long straw or boards to throw off heavy rains and snow. The crop obtained in this way will allow the house to be planted next May with young Vines. To save time at the planting season it will be well to do the necessary repairs to the house as soon as the Vines are pruned and to get the soil ready for the new Vines. The compost will be in better condition if the turf is cut now and stacked for the purpose. I like to place layers of horse manure between the layers of turf if the loam is poor. It is then in nice condition for planting and in much better condition for the roots than when large quantities of fresh manure are used at planting.

**LATE VINES.**—The most important work with late Vines will be preserving the fruit. To get bunches of the best quality all through the winter, it will be necessary to give some warmth to raise the night temperature and dry up excessive moisture; a very little fire-heat will arrest decay. It often happens that vineries are used to shelter Chrysanthemums, and with continued supplies of moisture to the plants the Grapes are injured. I would in such cases advise cutting the crop and bottling the same, as the fruit will keep much better in a cut state if the bottles are housed in a regular dry temperature and charcoal used freely in the water. After cutting, a thorough soaking

of water should be given to the portion of borders not covered by plants, as though there are regular supplies to the Chrysanthemums, a portion of the border near the base of the canes does not get moisture and the roots suffer. In the case of Grapes required to hang till the beginning of the year and late in colouring, every means should be taken to assist them. Here fire-heat will be necessary daily, and if the lateral growth is at all thick it should be thinned so as to freely expose the fruit and a genial warmth maintained. Ripe fruit will need to be frequently gone over with the scissors and bad berries removed, as one diseased berry soon affects those surrounding it. Large kinds of Grapes, such as Gros Colman, also need attention as the season advances. In their case it is well to go over large bunches, removing berries badly placed or much wedged against each other if required to hang till new Grapes are ripe. In the preservation of ripe fruits always whenever practicable admit air with a free circulation of warmth, and keep the house as free as possible from damp, giving a little air on the top ventilators at night as long as there is plenty of healthy leaves and the weather favourable. Should water at the roots be necessary to prevent shrivelling, select a bright day so that the moisture can dry up before nightfall.

G. WYTHES.

### KITCHEN GARDEN.

**LATE SUMMER VEGETABLES.**—Where due attention in the way of watering and feeding has been given, the latest supplies of Vegetable Marrows, French Beans, and June sown Peas will now be invaluable. A sudden and complete change, however, in the weather may be looked for at any time, as even with the tropical day-heat we have experienced during the past week or so the thermometer has descended to a low figure on several nights, frost having actually been recorded. Such being the case, he who would preserve the two first-named vegetables must be up and doing. Although it takes but little frost to render these quite useless, it is surprising how much frost a thin covering of canvas will resist. Leave it off as late in the evening as possible, the dews tending much to recoup the foliage after the distressing effects of a sunny day. I have seen better crops of Ne Plus Ultra and Criterion this autumn than I have met with for years, but the best gatherings were being made from rows which have been well supplied with moisture at the roots and were well syringed just as the blooms were formed with the lime and sulphur mixture so often recommended in these columns. Walker's Perpetual Bearer is gradually finding more favour as a late Pea, and certainly its general quality, combined with its mildew-resisting powers, warrants it. In large establishments where the demand for French Beans is constant, a sowing, or, better still, an indoor-raised batch, transplanted into a cold frame at the end of July will now be in a bearing condition, and will be sufficiently protected by night by simply drawing on the lights, covering with double garden mats by the middle or third week in October. Over-watering with these late batches must be strenuously guarded against, as stem-rotting, owing to a fall in the night temperature, will probably occur. Avoid dribblets administered often, rather allowing the soil to become fairly dry, and then giving a thorough drenching with diluted farmyard liquid, choosing a fine sunny day. The value of this yield will be seen by its filling a blank which always occurs between the destruction of the latest open-air lots by frost and the supply from the first pot-grown plants indoors. The early part of November affording a none too varied assortment of choice vegetables, those who sowed a row or two of Scarlet Runners at the end of June, and, instead of supporting the growth by stakes in the ordinary manner, allowed the haulm to a height of 2 feet, and then pinched out the leads as advised, will not only have found that so grown better autumn gatherings are obtained, parching sun and drying winds being excluded

With a minimum amount of labour, a rough framework may be built over one row at least.

**FORWARDING SEAKALE.**—In a season notorious for a minimum amount of rainfall, the probability is that extra plantings of Seakale intended for introducing into heat at the beginning of November will, especially where occupying sloping south or west borders, be sufficiently advanced towards maturity as to need no aid to the same. On clay soils on the level, however, crown ripening may be hastened by thrusting the spade right down to the lowest thongs and severing them. Extra robust plants may also have a portion of the strongest leaves reduced with a knife.

**WATERING WINTER SPINACH.**—In all my experience I never knew winter Spinach suffer so much from drought on light soils; even on land which had been cleared of other crops for weeks before sowing the seed watering has had to be resorted to. This is the only way of saving this important crop from destruction and supporting the weakened growth until rain comes. I use roses on the pots and water late in the afternoon. In seasons like these the benefit of making an extra sowing is seen, as seldom do two batches growing in different situations suffer similarly. I have again sown a few rows of the summer variety, having proved its frost-resisting powers last winter, and it certainly eats more juicy and refreshing. Be diligent in the frequent use of soot, or soot and wood ashes, stirring it in with a Dutch hoe previous to watering, as in gardens liable to the wireworm it and a dry root-run will speedily ruin the crop. Nitrate of soda is good for Spinach beds in dry weather, promoting a certain amount of moisture in the soil, but care must be exercised in its use.

**PREPARING PEA PITS.**—It is bad policy to postpone the preparation of pits and deep, cold frames where sowings of Peas are to be made in November and December until that particular date, as one is never certain what the weather may then be, and if snowy or frosty, the soil is worked to a disadvantage, resulting oftentimes in wholesale rotting of the seed. I always grow Chelsea Gem or some other early dwarf variety in cold pits, and like to get the soil ready by the middle of October. The plan I adopt is to take out trenches annually and to replace with quite fresh rich soil, first of all treading in a good quantity of farmyard manure. The soil in which Pines and Tomatoes in pots have been grown is quite suitable, as it contains much rich food, the result of artificial feeding throughout the summer. If a little quite new loam can be added and the compost after being duly mixed thrown in in a semi dry state, no rotting will be apprehended, and the Peas after sowing can be exposed to a good rain or two to secure perfect germination. This system is far preferable to merely digging the soil and adding manure in the orthodox way.

**PICKING OUT CABBAGES.**—After the required area has been planted with plants from the second sowing of the earlier varieties of spring Cabbage those that are left in the seed beds may well be pricked out closely on well-prepared firm ground in sheltered nooks or corners to stand the winter, as should the weather prove mild these are often of more value in spring than the ones wintered in frames, being stockier and more hardy, and going away better when transplanted. Cauliflowers may be treated in the same way, and dry leaves or branches thrown over the plants during sharp weather. Sometimes the latter will survive the winter if planted under walls similarly to Lettuce. The present is a trying time for freshly planted Cabbages on open quarters. Our soil was so dry that drills were drawn out the day before planting and filled with water, the plants being well watered again. Evening sprinklings with rosed watering-pots are also necessary to assist the plants to lift up their heads after such extreme heat. The same remarks apply to fresh planted batches of Endive. Established beds of the later salads, not having much longer to remain in the open ground, should be encouraged by liberal

supplies of liquid manure; the moisture will also secure a good ball at lifting time.

**PREPARING BEAN SOIL.**—The sooner a large heap of good soil is prepared for use in forcing early pot and box Beans the better, as it can then be stored away in some convenient corner where it will not become too dry, and can be covered with boards or thick Bracken should much wet set in. A small percentage of fresh horse manure and some approved artificial manure should be added to the soil. Those who force in shallow wooden boxes—a good old plan—should on wet days see to the repairing of the same, adding new ones if required. Everything will then be in readiness for a start at the end of October. Those who contemplate Bean forcing for the first time and are not acquainted with the best varieties for the purpose, will find Sutton's Dwarf Forcing, O'born's and Sion House useful kinds. J. CRAWFORD.

## STOVE AND GREENHOUSE.

### BEGONIA DISEASE.

I REGRET to see, from Mr. J. C. Tallack's communication in THE GARDEN for September 28, that his Begonias have been attacked with a disease of a terribly destructive character. The disease, or whatever it is, I find, extends to places wide apart. The early part of last August was the first time I became acquainted with it, when a friend of mine brought me some affected Begonia leaves from a garden nearly 100 miles away. I was quite unacquainted with the disease, but I could see at once that the leaves were affected with something very destructive. When placed under the microscope I could not find the slightest trace of insect life, nor did the injured parts of the leaves indicate that the disease was the result of insect agency. I can only describe the injury as a form of canker, which appears to attack the underside of the leaves first, and my friend tells me it eventually reaches the stem, and then the plants collapse. Whatever it is there is no doubt that it is a serious matter, as the gardener who brought me the affected leaves told me that in the neighbourhood of Gloucester it had proved to be infectious, as it had attacked the Vines in one house in which some affected Begonia plants were growing. So far as I know, it does not appear to have reached the plants that were growing in the open air, only those grown in warm houses. When the diseased leaves, to which I have referred, reached me, I naturally examined my own stock very carefully, and amongst some seedlings about four months old I found sufficient evidence to show that the plants were not free from the same enemy. I found five plants affected in the same way. These I instantly pulled up and threw away, and I have not seen any further signs of it since. Seeing that only plants growing under glass have suffered, it is very clear that cultural conditions have something to do with it. Some cultivators use too much manure for their Begonias and they use it too fresh. The best stimulant in this way that I can find is Moss litter after it has done duty in the stable and afterwards lain in a heap for three or four months. After being treated in this way and used in moderate quantities the roots of Begonias revel in it.—J. C. CLARKE.

\* \* The disease referred to is, we think, caused by thrips. It is not uncommon, though not perhaps so frequently noticed as this year, which has been so dry and favourable to insect pests.—ED.

**Brugmansia flore-plenc.**—In the conservatory at Rackheath Park, near Norwich, the resi-

dence of Sir Edward Stracy, is a very fine specimen in standard form of this fine old greenhouse plant. It has attained to a great height and covers a large area, this being the result of a rich larder and liberal feeding. When I saw it at the beginning of September it was covered with bloom, and presented a very novel appearance. Camellias also do wonderfully well in the same structure, this also being attributed to the extra room they enjoy. In many conservatories the borders for Camellia roots are far too limited in size; hence, being free-rooting plants, they soon fill them to overcrowding, rendering it next to impossible to support growth even by liberal feeding. It is well when the borders can be enlarged as the trees increase in size, as nothing resents a sour mass of soil more than Camellias.—J. C.

**Eucalyptus citriodora.**—Scented-leaved plants are grateful to nearly everyone, and among them is the old Lemon-scented Verbena (*Aloysia citriodora*), to whose perfume that of the *Eucalyptus* in question bears a great resemblance. It is a less vigorous grower than many other species of *Eucalyptus*, and if allowed to grow away without stopping it forms a thin-growing subject bare of leaves at the base. To obviate this as far as possible the young seedlings should be stopped freely during their earlier stages in order to assure a bushy habit of growth. In the case of plants that have been allowed to run up thin they may be cut back hard in the spring, and as they generally break out well, one has not long to wait for an ample crop of leaves. These leaves are oblong-lanceolate in shape and covered with glandular hairs, from which the perfume is emitted. This *Eucalyptus*, in common with most members of the genus, produces two totally different kinds of leaves, and it is only the young and juvenile foliage that is scented, the mature leaves being smooth and nearly scentless. However, as a rule this species will attain the dimensions of a good sized plant before any adult leaves make their appearance.—T.

**Sarracenia flowers, scent of.**—The curious, but beautiful flowers of *Sarracenia flava* are well shown on the coloured plate in THE GARDEN, September 14, and in the accompanying article attention is directed to the ornamental features possessed by the blossoms of some other species. One item, however, I did not see noticed, and that is the great difference that exists among the various forms with regard to the odour of the flowers. For instance, the deep red blossoms of *S. rubra* emit a delicious Violet like perfume, which during sunshine is especially pronounced. *S. flava* has when in flower quite a disagreeable smell, while *S. Drummondii* and *S. purpurea* are almost scentless. From a flowering point of view alone the *Sarracenia*s certainly merit attention, as when in full bloom they are very attractive and remain fresh a considerable time. Taken in conjunction, too, with their singular pitchers, they form quite a unique feature in the greenhouse. *Sarracenia*s seem to be a little more popular now than was the case two or three years ago, though some fifteen years since or thereabouts there was a fair demand for them, and some of the principal nurserymen made quite a feature of the best forms.—H. P.

**Lilium sulphureum.**—This Indian Lily, which was at first known as *L. Wallichianum superbum*, is just now beautifully in flower, and forms a very attractive feature in the greenhouse. Its long tube-shaped blossoms are almost white, tinged more or less on the outside with purple, while the interior of the flower is heavily shaded with deep primrose. This Lily is unlike most of the other Indian species, as it succeeds under cultivation in this country, and does not deteriorate in the same way as *L. nepalense* and *L. neilgherrense*. It is frequently very late in starting into growth, but when once the stem makes its appearance it grows away rapidly. If grown in pots for the embellishment of the greenhouse it will be found a good plan to plunge the plants out of doors during the summer till the flower-buds are well developed,

otherwise if kept altogether under glass they run up tall and weak. Apart from its magnificent blossoms, this Lily is also remarkable from the vast numbers of leaves produced by a single plant, and more particularly by bulbils being borne in the axils of the leaves on the upper part of the stem, as in the case of *L. bulbiferum* and the Tiger Lilies. Up to the introduction of this species the peculiarity in question was unknown in the Eulirion or tube-flowered group. The bulbs of *L. sulphureum* are large and mahogany coloured. Small bulbs of this species are very difficult to distinguish from those of *L. nepalense*.—H. P.

**The Tree Carnation.**—Mr. A. Hemsley's article is full of interest, and opens up the question as to the origin of the Tree Carnation. The works published on the culture of this flower give little or no information on this point. I once put the question to Mr. E. S. Dodwell, and his opinion coincided with my own in attributing the Tree Carnation to the selection of one of those stems the ordinary summer blooming types are apt to put forth, namely, a shoot which, instead of throwing up a flowering stem, lengthens considerably and is covered all the way up with small side shoots. One of these grown on flowered during the winter, and cuttings taken from such a plant laid the foundation of the tree section, and it is only natural a propagated plant should transmit this peculiarity. The treatment adopted, *i.e.*, the time when the cuttings are struck and the placing of the plants under glass, will determine the season of blooming. Last spring when I was visiting the Royal Nursery, Slough, I saw in one of the houses there was a very fine lot of two year-old plants of Germania of most vigorous growth and throwing up a number of flower stems; the forwardest buds were already expanding. Mr. Harry Turner said that such plants produced much finer blooms than yearling ones, and I could see that it was so. One very satisfactory feature about the present race of Tree Carnations is the reduction in the height of the plants which prevailed thirty years ago. Improved methods of cultivation have had something to do with this.—R. D.

#### CARNATIONS FOR WINTER BLOOMING.

MR. WEGUELIN'S remarks on p. 218 respecting these are somewhat misleading, inasmuch as they infer that the ordinary border varieties can be made to bloom throughout the winter. Mr. W. says, "Carnations, if properly understood, can be had in flower all the year round," and then adds that he exhibited a stand of plants at the Plymouth Chrysanthemum show in November. These plants I saw, but in no sense could they be considered "winter blooming." The varieties were simply border ones, but their blooming, or running for bloom, was more the result of chance than design or culture. Out of a large collection of border sorts it is in most seasons possible to pick out a dozen or so plants showing buds early in the autumn, and these, if potted up, will bloom for a few weeks, but can hardly be termed winter-blooming varieties, and something different is required by our large growers who grow enormous quantities of bloom throughout the winter. Very few can have any idea of the extent Carnations are grown to supply Covent Garden with blooms during winter. I know of one grower who has a stock of eleven thousand plants in one variety only.

The Americans undoubtedly grow Carnations extensively. I hear one firm has a stock of seven thousand large plants of a novelty, and the whole will be propagated from throughout the winter, and the number of plants which will be produced will seem almost incredible. The American growers are not successful with our most popular varieties, but their mode of culture has a great deal to do with their non-success. They strike cuttings in spring, and the plants are put out in the open fields, where they make good growth. In September they are lifted and benched, that is

planted out in beds or shelves in the greenhouse. The American standard of excellence is different from ours. Here we prefer varieties with round and smooth edged petals; in America preference is given to blooms with a rough or serrated edge. The famous Uriah Pike is at a discount in America for the following reasons: the colour is too dark, it is not free-flowering enough, and has smooth-edged petals.

Mr. Weguelin gives a list of varieties he has just received from America for trial. Many of them have been grown in this country for some years, and are vastly inferior to our English varieties. I will describe a few as I have found them. Lizzie McGowan, white, very free-flowering, but thin and of poor form; plant, a weak grower. Daybreak, delicate pink, irregular in form, one of the best. Bouton d'Or, pale yellow, striped purple, good large bloom, but a very slow grower. Buttercup can hardly be considered a perpetual, being more of the border type, not free-flowering either in this country or America. Wm. Scott, pink, also very much fringed, utterly useless to the "up-to-date" grower. Uncle John, white, is larger and fuller than Lizzie McGowan, but not a clear white. W. J. GODFREY.

Exmouth.

**Rooting Poinsettias.**—It is often difficult to procure Poinsettias sufficiently dwarf for use in ornamental baskets and vases for drawing-room decoration unless struck very late, and then a satisfactory growth is often lacking. A capital plan of securing dwarf plants is adopted at Blickling. It consists in making an incision half-way through the stem, just below a joint, and mousing the wound over. If done in August the plants callus over by the end of September, and if then detached and placed in small pots and plunged in a brisk bottom-heat they very quickly root and come in most useful where dwarf plants are in request. I may add that when the tops are taken off and potted the Moss is allowed to remain on.—J. C.

**Propagating variegated Yuccas.**—The variegated Yuccas, such as *Y. aloifolia variegata*, *Y. quadricolor*, and *Y. filamentosa variegata*, are, in the shape of small plants, very ornamental in the greenhouse, and in some places they are always grown for this purpose. Neat plants in pots from 6 inches to 9 inches in diameter are, as a rule, the most useful; hence it is necessary to propagate a few occasionally in order to keep up the stock, as some may grow too large for the purpose. A limited number can be obtained without injuring the stock plants in any way if the following directions are carried out. In the case of plants in small pots it will be often noticed, at this time of the year especially, that there is a tendency for the ball of soil to be lifted out of the pot. An examination will reveal the fact that this is caused by very stout sucker-like growths, which contain at the apex an embryo plant, and if allowed to remain undisturbed it would finally reach the surface and push forth leaves. To obtain these suckers the ball of earth should be turned out of the pot, when the sucker-like growths will be found at the outside of the ball, and in nearly every case with a sharp knife they can be readily separated at a length of 3 inches or 4 inches. This is sufficiently long to leave in most instances some fibrous roots attached to the suckers, which should be potted in small pots, using for the purpose a soil composed principally of sandy loam. The growing point of the sucker should be placed in the centre of the pot and at such a depth that the upper portion is just covered with the soil. Then if the pots are plunged in a gentle bottom heat they will soon push forth leaves and form neat little plants. Of course, where large plants are given up to propagating purposes the crown may be taken off and struck, and the young shoots produced from various parts of the stem after the removal of the top may, when large enough, be similarly treated, but by the first-mentioned method no disfigurement of the stock plants is necessary. Dracenas of various kinds, more par-

ticularly the well-known *Dracena* or *Cordyline australis*, may also be propagated by means of the stout sucker-like growths, or toes, as they are popularly called.—T.

**Datura cornucopæa fl.-pl.**—This fine new species seems to require more warmth than the older herbaceous kinds. Grown here in pots under glass with *D. chlorantha*, *D. Huberiana* and *D. meteloides*, and given the same treatment, it opened its flowers very tardily, while the others bloomed freely enough; in fact, I believe but for the bright, sunny season they would not have opened at all. I hope it may prove perennial wintered in an intermediate house like *D. chlorantha* and *D. meteloides*. The advantage of wintering them is that they flower more freely and become finer specimens. I regret I did not plant out one or two, for with good soil and the abundance of sunshine which we have enjoyed it would have made more vigorous growth and very likely behaved differently. All the *Daturas*, including the *Brugmansias*, are great favourites of mine, and I can never have too many of them. Many years ago (perhaps forty) I grew several other annual kinds, all more or less attractive. Amongst them were *D. carthaginensis*, *D. ferox*, *D. quercifolia*, *D. Tatula*, *D. humata*, *D. levis*. Seed of none of these is now obtainable. *D. gigantea*, seed of which I received from Africa, is a very robust annual species, growing in rich soil to the height of 5 feet or 6 feet, with black stems and a much-branched, spreading head, but the flowers are small—not larger than those of *Datura stramonium*, of two shades of blue. Like *D. stramonium*, it will generally sow itself, and, like it too, its seeds retain their vitality a long time in the ground. A bed deeply dug here this year yielded quite a colony of plants, yet none had been growing there for three or four years. It is a distinct plant and worth its room. I have often tried to cross the *Daturas*, but have never once succeeded. I hope the known, but un-introduced, species will soon be amongst us, or it will be too late for us aged gardeners and their ardent admirers to make their acquaintance. All the herbaceous *Daturas* should be sown as early as possible to obtain the best results, and nothing suits them better than a brisk manure hot-bed in which to push them on.—J. M., *Charmouth, Dorset*.

## ORCHIDS.

### MILTONIAS.

SEVERAL of the species belonging to this genus are among the finest of our autumn-flowering Orchids, and cannot be well dispensed with in collections whatever their size. They are natives of various parts of the American continent and the majority of the species are of easy culture. All are pseudo-bulbous epiphytes, some growing in clusters, others at varying distances apart upon creeping rhizomes, and the majority are free-blooming, handsome-flowered Orchids. The genus was named by Lindley in honour of Viscount Milton. The majority are easily propagated by division of the pseudo-bulbs. Several of the best kinds are remarkable for the pale green colour of the pseudo-bulbs and leaves, especially *M. spectabilis*. This is sometimes looked upon by amateurs as indication of ill-health and supposed remedial measures taken, but as it is natural to them no special treatment is needed or will have any effect upon this. *Miltonias* like a very free and open root-run, and as a rule not too much of it. An abundant supply of water is needed, especially while growing freely, and on this account good drainage kept free is one of the first considerations. Some do best in pots, others in shallow pans or on rafts, but these will be best described below. They all without exception like a good clear light, but none of them will stand direct sunshine, so that a little shading is

necessary in hot weather. But the growth must be ripened, or else it is useless to expect flowers of good quality or in sufficient numbers to make them worth growing.

*M. ANCEPS* is a very old species, having been brought from Brazil in 1851. It has always been an uncommon plant, and was for a time supposed to have been lost to cultivation. In habit it resembles a small-growing form of *M. spectabilis*, the flowers also being similar in shape to those of this fine Orchid. The sepals and petals are of varying shades of green, with markings of reddish purple, while the lip is white with a few red spots. The best way to grow this kind is on a raft very lightly dressed with peat fibre and Sphagnum, giving it a light and airy position in the *Cattleya* house.

*M. CANDIDA* is an easily-grown, free-flowering kind, introduced from Brazil in 1830. This has flowers upwards of 3 inches across, these being produced in racemes of seven or eight on strong plants. It is not uncommon for this plant to bloom twice during the year, but its usual flowering season is in autumn. Pot culture suits it well and it thrives in a mixture of peat fibre and Sphagnum, to which may be added a good sprinkling of charcoal or crocks, the whole overlying good drainage. During its growing season an abundant supply of water is required, and even when resting it should not be dried. This dislikes much sunlight, and may be grown in the shadiest part of the *Cattleya* house. It is a variable kind, the type having yellowish segments barred and lined with reddish brown, and the lip is pure white. There is a yellow-lipped kind, *glaucescens*, and also a large-flowered variety, *grandiflora*. Another fine autumn blooming species is

*M. CLOWESI*, similar in habit and cultural requirements to *M. candida*, to which its flowers also bear some resemblance. These are produced on erect scapes, and have sepals and petals chestnut-brown tinged in places with yellow, the colours running into each other. The cordate lip is white with a deep purple base, and the flowers last well for a month or five weeks. A larger form of this, *M. C. major*, is superior to the type, and there are other named varieties. A Brazilian kind introduced in 1843, as was also

*M. CUNEATA*, a free-growing and abundant flowering species of larger growth than the majority. This thrives best in a brisk, moist heat with plenty of sunlight, and produces its flowers in spring. The racemes contain about five flowers, each 3 inches or more across. The wavy, dark brown petals are greenish yellow on the points, the lip white, spreading, and spotted with rose colour. Pot culture in peat and Sphagnum suits it well.

*M. PHALANOPSIS*, *M. Roezli* and its varieties, and *M. vexillaria* are all natives of New Grenada, found at great elevations. The pseudo-bulbs are clustered, leafy, and bear spikes freely from the axils of the latter. Their culture differs somewhat from that of the other *Miltonias*, and they are frequently known as *Odontoglossums*.

*M. REGNELLI* comes from Brazil and is a pretty species, thriving well under the same conditions as *M. cuneata*. The flowers, borne on erect scapes, are each about 2 inches across, pure white, with a rosy purple lip also margined with white. It is an autumn-blooming kind, lasting about a month in good condition, and was introduced in 1864.

*M. SPECTABILIS* is a well-known and handsome species, and one of the most variable in the genus. The pseudo-bulbs, about an inch apart, occur upon a creeping rhizome, and, with the leaves, are light yellowish green. This species does well on rafts with peat and Sphagnum, and must only be shaded sufficiently to prevent scorching. The plants must be firmly fixed in the first place, after which the roots cling tenaciously to the sides of the raft. Plenty of water is needed all the year round, less of course during winter than in summer, but the growth must never be allowed to shrivel. The flower scapes appear in autumn, and

each bears a single large flower. The sepals and petals are creamy white, the lip spreading, rosy purple with deeper lines. The beautiful variety *Moreliana* has flowers wholly of a deep purple, the lip shading to rose, and is a truly handsome kind when well grown and flowered. There are several sub-varieties of this and also many other varieties of the type, including *M. s. radicans*, a pretty form with a creamy white lip and radiating lines of purple; *M. s. rosea*, *aspera*, *lineata*, and others, all beautiful kinds, differing more or less from the type, which was introduced from Brazil in 1837.

*M. WARSCEWICZI* is a Peruvian kind of a very distinct habit and inflorescence. The scapes are branching and many-flowered, the individual blossoms being 2 inches across, the sepals and petals reddish brown tipped and margined with yellow, lip brownish purple with a rosy margin. The plants, which flower at various times in the year, may be grown in a shady corner of the *Cattleya* house. R. H.

### DENDROBIUM BIGIBBUM.

THE richly-coloured flowers of this *Dendrobie* are just opening, and it forms a good companion plant to its near ally, *D. Phalaenopsis*. It can hardly be styled a difficult plant to grow, for when systematically treated it usually does well. Still the fact remains that many fail with it, and this from want of thought more than anything. In order to grow *D. bigibbum* well a strong moist heat is needed, and as the young shoots frequently start late in autumn, this has to be kept up all through the winter. It cannot then be accommodated with the ordinary deciduous species of the *Wardianum* and similar types, but must be separated from them as soon as they are on the move. A house devoted to winter Cucumbers makes a good home for *D. bigibbum*. The resting season even of East Indian plants necessitates a considerable drop in the temperature of this house, and it therefore falls below the requirements of this heat and moisture-loving kind. It dislikes a large body of compost about its roots, but what little is provided must be kept sweet and open. If the peat by constant watering becomes sour and close, it will be found advisable to repot, or at least to surface-dress the plants yearly, but once in two years usually suffices if the material used is good. Small suspended pans may be used, as by this means the plants are brought close to the glass and get the full benefit of light and air. Syringing overhead may be practised with safety as long as the weather is bright and hot, but as soon as dull weather sets in this must be discontinued, or the loss of many of the growths will be the inevitable result. The pseudo-bulbs when fully grown must be well ripened, and if the outside conditions permit, the plants should be placed in a sunny frame where the lights can be drawn on at night. Towards the end of summer the flower-spikes will be showing, and the plants will require to be placed again in heat. These usually show most freely on the bulbs of the second year, but it is not uncommon for the newly-formed ones to produce a few flowers, especially after a hot, sunny season. The old bulbs go on flowering for several years; in fact, until they become too weak to do so. The spikes are erect, or nearly so, and bear many flowers, these being of a rich magenta purple with a white crest to the lip in the type. Several varieties are described differing from this both in size and colour, and they all flower during late autumn. *D. bigibbum* is found in Northern Australia, and is an old plant in cultivation, having been introduced in 1824.

***Cattleya bicolor***.—The distinct appearance and colour of this *Cattleya* should ensure it a place among autumn-flowering species. It is not very showy, but very interesting. The pseudo-bulbs grow about 30 inches high, and each bears on the apex a couple of leaves, from between which the flower-scapes are produced. On strong plants

these bear as many as a dozen or fourteen of the singular flowers, each about 4 inches across. The petals and sepals are greenish when the flowers open first, afterwards turning to an olive-brown. The lip, which is peculiar in having no side lobes enfolding the column, as is usual with this genus, is a pretty tint of purplish crimson, becoming paler towards the margin, and in some varieties having a broad marginal band of white. The usual *Cattleya* house temperature suits *C. bicolor* well, but it requires more shade than most other kinds. The compost may consist of equal parts of peat and Sphagnum, with plenty of rough nodules of charcoal and potsherds added, the roots being large and delighting to ramble about these rough, hard surfaces. It requires careful watering at all times, but especially during autumn and winter, for the roots, though large, are easily damaged by too liberal a supply. It is found growing naturally on tall trees in Brazil, and was introduced in 1837.

**Angræcum bilobum.**—This pretty and compact growing Orchid does well in small baskets with a very little live Sphagnum about its roots, and just now its elegant drooping racemes of small white flowers are very attractive. Coming as it does from New Guinea, it likes ample heat and an atmosphere dripping with moisture. The basket should be hung up near the glass, but in a shady position, as the leaves are easily injured by bright sunshine. The state of growth must be the guide to watering at the roots, which must not be allowed to shrivel in winter.

**Cypripedium Charlesworthi.**—I have just received a beautiful variety of this superb Cypripedium, the dorsal sepal being very broad and of a lovely warm rosy pink shade, made all the more attractive by the distinct white staminode plate. This is bound to become extremely popular, for not only is it one of the most distinct and pretty in the genus, but it seems to grow as freely as an ordinary *C. insigne*. In habit it closely resembles *C. Spicerianum*, the leaves being blotched on the under surface with dark brown. It thrives in the warmest house in a shady position and likes a good proportion of fibrous yellow loam in the compost, care being taken not to make it too heavy, and by giving good drainage to prevent its becoming waterlogged.

## FLOWER GARDEN.

### HARDY CRINUMS.

If a test of hardiness was ever needed it was undoubtedly forthcoming during the winter of 1894-95, and any plant that withstood the severity of that frost may justly be regarded as perfectly hardy. After such an exceptionally severe spell I was interested while on a recent visit to the Botanic Gardens, Birmingham, to note two Crinums, viz., *C. Powellii* and *C. longifolium*, in the fullest health and vigour. These had remained outside for several years past, including last winter, without any protection beyond that afforded by a south-west wall which formed the end of the cool conservatory. The main secret of success with such things is deep planting; this is absolutely essential with these and similar bulbous plants. To be more explicit, it should be stated that by deep planting it is always intended that at planting time the top of the bulb should be fully 8 inches under the surface. To secure the necessary depth and at the same time provide suitable material for the roots of these plants, it will be needful in many gardens where the soil is clay, or of a very shallow nature, to remove the original soil to a depth of 2½ feet. The best way, or at least the simplest and most inexpensive, will be to take out a narrow trench one foot wide to the above depth. When the trench is deep enough, some rough clinkers, broken bricks or pots to the depth of 6 inches

should be first placed in the bottom for drainage, afterwards filling in with good loamy soil, peat, and leaf-mould. Sharp sand may be employed liberally about the bulbs, and well-decayed manure to enrich the whole may be worked in at a fair depth below the base of the bulbs, remembering always in this connection that the roots of such things go straight down and that the food should be where the roots invariably descend. In a narrow border prepared on these lines, such things as the *Crium* above named, together with the *Belladonna Lilies*, which in reality are a host in themselves, may be grown infinitely better than by any system of pot culture under glass. Take the latter for example, and these for the past week or two have been making a grand show in a narrow border at the side of the Orchid house at Kew. Some of the bulbs must be of great size, as I noticed recently as many as four and five spikes issuing apparently from one root cluster. Indeed, the proximity of the spikes was such that the flower spikes appeared to be issuing from what was originally one bulb, but now of such a size that the offsets were flowering, while the succession in which they came confirmed the idea that all came from one root-stock. This is a splendid result, and simply an instance of what such things will do when fully established. And in just a similar way may these plants be grown in private gardens. One very charming kind at Kew is called *A. B. blanda*. In the spring-time the border set apart for such things should be aglow with white and blue Wood Anemones, *Chionodoxas*, *Iris reticulata*, and later with any such Daffodils as *Emperor*, *Horsfieldi*, *Empress*, *Grandee*, or *Sir Watkin*, to give place in summer time to the *Crimmums* and *Amaryllis Belladonna*. For still later flowering, if space permitted, may be included *Lilium speciosum Krætzleri*, whose leafy stems would act as a foil to the *Belladonna Lilies*. E. J.

**Macrotomia echioides.**—Judging by the present labelling at Kew, this appears to be the up-to-date name of the plant recognised by the generic name of *Arnebia*. Of the wisdom or otherwise of the corrected name I have nothing to say. But seeing that the generic name of *Arnebia* has been now so long in use that it is known everywhere, it comes as a surprise that the old name finds no place on the rock garden specimen at Kew. The generic name above cited, so far as the *Arnebia* is concerned, appears also a new creation, as I find no mention of *Macrotomia* with the other synonyms for *Arnebia* in the "Dictionary of Gardening." While admitting the necessity of providing new names in certain cases, I am of opinion that the gardening public would be much assisted if the Kew authorities submitted an official list of such alterations to the leading horticultural journals from time to time. Such a list would be most useful to all interested in correct nomenclature, while to those at a distance from the metropolis it would come as a boon.—H. M.

**Liatris (Blazing Star).**—This distinct and interesting North American plant is by no means common in gardens, as at the most one sees but one species, and that generally is *L. spicata*. Just at this season of the year the species of *Liatris* afford quite a distinct tone of colour in the garden, and for this reason alone are worthy of remark. Quite recently I noted three members of this genus flowering in the rock garden at Kew. The most showy is *L. scariosa*, a plant not always obtainable true to name. It is about 3 feet high, and makes a good display of its manve-purple blossoms at one season. In the case of *L. spicata* and *L. pycnostachya* the flowers, curiously enough, commence expanding, from the top of the spike, and continue opening downwards. This characteristic is seen in but few plants. *L. pycnostachya* attains to nearly 6 feet high, and produces its pale reddish purple flowers in a

dense cylindrical spike. The leaves are usually narrow or lanceolate and rigid, the growth more or less erect, so much so that a dozen plants would have ample room in a space of 3 feet. These plants are easily cultivated in any ordinary garden soil, the last-named species being valuable by reason of its adaptability to dry soils. All the kinds are readily increased by seed, which may be sown as soon as ripe or in early spring, or the rootstock may be divided with ease and certainty either when flowering is completed or with returning growth in spring.—H. H.

**Heuchera sanguinea.**—In the Rev. C. Wolley-Dod's remarks on this plant I was surprised to read that cold situations and cold winds must be avoided. I have grown this plant by the thousand for some years in the open fields. I have one lot growing in loam and another in very light soil, and both bloom and grow very freely. The cause of not flowering is, I think, too rich soil.—B. LADHAMS, Southampton.

**Ioeris gibraltaria.**—This is perhaps the largest as well as the showiest member of the Candytuft family. It is, however, doubtful whether we see it at its best when regarded as a hardy border plant. Indeed, it rarely survives our more severe winters, and if it succeeds in passing through a moderately severe one, it is seldom satisfactory afterwards. The plant will frequently, when grown in warm well-drained soils and positions, survive an ordinary winter. Plants raised from seed sown in March or April, preferably in the open ground, as they do not transplant readily, will be strong, and should they survive the winter they will make a fine display the ensuing spring and early summer. On light sandy soils the plant is usually a success, and the large heads of delicate lilac flowers are very showy. It may be raised freely from seed. On this account it is not worth the trouble of increasing by cuttings, unless it be an exceptionally fine kind. In my experience of it, the cuttings are liable to canker instead of rooting in the usual way. By treating it as a biennial, sowing the seeds in the open or thinly in pots, a supply may easily be kept up. As a pot plant for the conservatory it is very useful, and the flowers lose much of the lilac hue that they assume out of doors. For this purpose when well grown the flowers are nearly pure white and very effective. Under glass a cool, dry, and airy position should be always given it. Heat is the reverse of beneficial, and if applied the plant quickly becomes weak and useless.—E. J.

**Japan Anemone Lady Ardilaun.**—I lately saw a group of this Anemone in Mr. Ladhams' hardy plant nursery. It was growing in the sandy and stony soil with great freedom. I did not notice any trace of the disease "J. C. B." speaks of on p. 198. Individually the plants are much finer than the type, being more compact and flowering more freely. The extra stiffness of the peduncles is a point in its favour. The leaves are sturdy and have a glossy look about them which is pleasing. I think this Anemone will out the older form when it becomes better known. Growing as I saw it in such hungry-looking soil and especially during the recent hot and dry weather that it has had to contend with, is really a thorough test of its non-liability to disease. The variety Whirlwind, growing alongside as I saw it, I look upon purely as a monstrosity, a good flower spoilt by the intermixing of the petals and green calyx-like substance that the flower is composed of.—E. M.

**The Japan Eulalias.**—The Fan Grasses or Eulalias of Japan are now, I believe, placed in the genus *Miscanthus*, but it will probably be some time before the later name becomes current, and so we may stick to Eulalia, for the present at least. I have long grown these beautiful Grasses, both green, striped, lined and bared, but never saw their fan-like plumes so profusely produced or so fully developed as they are this season. It is, I suspect, the late hot sunshine that has thus stimulated them into unwonted beauty. Even though these plants never flowered, they would

always be valued for their freshness and grace in the garden, but the inflorescence is an added gain, as each grassy stem, 5 feet to 7 feet in height, is topped by a feathery fan of dark reddish purple, from which the golden anthers dangle and shimmer in the hot sunshine in a very pretty way. Later on the spikes become a mass of silvery fluff, and remain bright and beautiful all the winter unless they are cut for decoration.—F. W. BURRIDGE.

#### FLOWER GARDEN NOTES.

**AUTUMN PLANTING.**—Many, indeed most, of the summer bedding plants are now practically over, and if it has been decided to make additional plantings of herbaceous subjects in lieu of more tender things, the beds can be cleared of the latter and will be ready for the replanting when

nently to the fore in recent years, and have been planted largely not only in odd nooks and corners, but in the best places in the flower garden that were formerly given over entirely to tender plants now that the cultural skill brought to bear upon them has proved that they will furnish a very prolonged display of flower. Take Phloxes as an example. Not only can the season be prolonged by grouping together the suffruticosa and decussata sections, but in the latter family alone the flowering is lengthened in three ways—by allowing some to develop to the utmost the first spike, by taking this out when the pipe first show a sign of decay, and by pinching this first spike out as soon as it shows signs of coming up. Beds planted entirely with Phloxes and treated in this way may not give a dense mass of colour at any one particular time, but the display starting in August will be well sustained until

prices if there is not a stock already in hand. A good bed for another year would be bold groups of Newberry Gem Pentstemon on a groundwork of Veronica incana. Having decided on the bed to be planted in this way and the size of the clumps of Pentstemons, the Veronica incana may be planted as soon as convenient, and will be a nice silvery carpet throughout the season of 1896, whilst cuttings of the Pentstemon may be at once inserted if not already done. This is one of the older varieties, but still one of the best for bold grouping. The hardiness of Lobelia cardinalis on this soil having been established, I shall plant a bed this autumn with alternate clumps of this and Gypsophila paniculata, giving a good mulching of half-decayed leaves about 2 inches in thickness. The Gypsophila is over somewhat early in the season, but is beautiful in its decay, the tiny seeds holding well on the long feathery spikes. A

*View in the grounds at Castlewellan. From a photograph by Lord Annesley.*

circumstances permit. It is now advisable, by the way, to leave it until after the middle of November, as after that date a severe frost may put an end to all planting operations for the present year. Reference has often been made to the advisability of getting out in good time such things as Tufted Pansies, Pinks, Carnations, &c., and good plants from cuttings or layers should now be ready. Where anything is to be associated with the Tufted Pansies through another summer, care should be taken to think of this when planting that the contrast may be a pleasing one. I may just note in connection with Carnation planting that if the weather continues as hot and dry as at the time of writing (September 23) and the soil is naturally light, a good mulch should follow immediately on the beds of planting, especially if the layers are not too well rooted. In addition to the above-named hardy plants other things of somewhat larger size have come promi-

the advent of frost, and if, as noted above, the two sections are grouped together, a flowering season of nearly five months is easily obtained. The wonderful improvement in the substance of pipe enables the new varieties to be used freely in a cut state, and the reduction in height is another point in their favour when used for prominent beds on lawns. They are long-suffering plants, that is, they will grow and flower in soils and situations where other things would fail, but are at their best in a border where the soil is fairly good and has been worked to a depth of 18 inches, and they are greatly benefited by a mulching of half rotten manure, which can be put on as soon as they are planted. Let me confidently recommend one or two beds of Phloxes to those who contemplate increasing their herbaceous plants. New varieties of the current season will be found rather expensive, but good old sorts can be secured at reasonable

rather interesting combination for a dry spot can be effected by grouping some of the Megaseas with Sedum spectabile. These plants are somewhat alike in their requirements, and the difference in the flowering season gives a longer display. In some of the families of herbaceous plants that are represented by very many varieties the pronounced difference in the height enables one to group them together in large beds without introducing anything else. This is noticeable in the Starworts, which range from 1 foot to (given a fairly strong soil) nearly 7 feet. It is not, however, advisable to "make extremes meet" in planting, but rather to work down by degrees, and the great variety in heights enables one to do this. As an instance of a good combination, I may mention Aster Novae-Angliae roseus, vimineus and dumosus. Take the Campanulas, again: a very interesting bed can be planted with these alone in variety, and the difference in height is

almost as marked as in the Starworts, ranging from those sorts with tall spikes nearly 5 feet in height to the trailers that will hardly reach 12 inches. It is not advisable to fill beds entirely with those things whose flowering season, although brilliant, is comparatively short lived. In the case, therefore, for instance, of the *Hemerocallis* and *Funkias* in variety, other things may be associated with them which will at the same time harmonise well in the matter of foliage and give a display of flower at other times than is afforded by the Day and Plantain Lilies.

**FLOWERING SHRUBS.**—If any planting of these is to be carried out this autumn the same discrimination should be shown as that practised with herbaceous plants. It may be noted in the first place that, even if the planting is only on a small scale, sufficient of each variety should be grouped together to afford a nice display; this is always much more effective than dotting a great number of subjects together in single plants. Very bright at the present time are bold groups of *Hydrangea paniculata*, especially if they are backed by a bit of bright foliage such as is furnished, for instance, by *Prunus pissardi*. In the very front rank of ornamental shrubs must be placed the old, but very beautiful *Rhus Cotinus*, and room should be found for at least one or two small groups. The white, flesh-coloured and pink forms of *Pyrus japonica* are very interesting just at present from the fact that they are fruiting freely, and later, when the fruit has put on its golden tinge, the plants are quite a striking feature. *Spiraea Thunbergi* and *S. prunifolia* fl.-pl. can always be recommended as shrubs with delicate foliage and throwing big sprays of beautiful flowers. Other useful things for spring cutting are the white form of *Weigela* and the large-flowered *Philadelphus*. Apropos of the desirability of strengthening in gardens the herbaceous plants and choice flowering shrubs in lieu of tender subjects whose beauty is so soon at an end, I have noticed this year an instance on a small scale in the case of two cottage gardens side by side, the one planted entirely with *Geraniums*, *Calceolarias* and *Lobelias*, which must have been obtained at some considerable cost, the other relying on old-fashioned perennials, which were, by the way, very well arranged. For a brief season the first named was very gay, but it was short-lived, and for a considerable time it has been dull and comparatively flowerless, whilst the neighbouring garden is all ablaze with, among other things, perennial *Sunflowers*, Japanese *Anemones*, both white and rose, late-flowering *Phloxes* and *Antirrhinums*, whilst in the front alternate clumps of the old double *Chamomile* and a dwarf blue *Campanula* form an appropriate finish to a very interesting picture.

Claremont.

## SOCIETIES AND EXHIBITIONS.

### FRUIT SHOW, CRYSTAL PALACE.

SEPTEMBER 26, 27 AND 28.

THE interest in this, the second of the large autumn exhibitions at the Crystal Palace held under the auspices of the Royal Horticultural Society, has been fully sustained. Never before perhaps have so many fruit growers (both the trade and private growers) been gathered together as at this show. The exhibition itself was a grand display of British-grown fruit throughout, affording, we may fairly surmise without being egotistical, a very good example of this important industry to our Continental neighbours and colonial subjects, better than which it would be difficult to find outside of the three kingdoms. There was throughout nearly all the exhibits of hardy, *i.e.*, outdoor, fruits ample evidence of high-class finish, the weather of late greatly favouring this development. The Kent exhibits, although excellent, were not this year so far in advance of those of other districts as at the previous show. This was in a measure encouraging, for any undue and

repeated monopoly could not but have a tendency to dishearten those outside of the favoured county. It is quite evident that a great amount of interest is shown in this gathering of fruit growers, and it is greatly to be hoped that it will not abate. Regarded in a collective sense, this exhibition was better than that of last year. This advance was more apparent in the Apples than in any other produce; the improvement therein was evident both in the size and quality of the best exhibits, whilst the competition was far more keen than on the last occasion, very many examples of high-class culture having to be passed over without any award whatever. Even if looked at from a commercial point of view only, an inspection of the hardy fruits to be seen in such abundance and of such high-class quality, one most instructive lesson was fully apparent, *viz.*, the utter folly of still adhering to the old worn-out orchards which have long ceased to be really remunerative to the cultivators. Cultivation is, perhaps, scarcely considered by some, it being more of a haphazard policy. It is quite time, however, that all old ideas were abolished where no sufficient proof exists of profitable returns. The clinging to quite old sorts, now entirely surpassed by greatly improved varieties, is an utter mistake. As a late Apple, Prince Albert is an instance of this amongst cooking kinds, as Cox's Orange Pippin is amongst dessert varieties. On the other hand, if we leave profit from a business point of view out of the question, it is infinitely more enjoyable to have our trees laden with fine fruits rather than with scrubby ones. From the side of beauty alone during the progress of development it is all in favour of the younger and more vigorous trees, whether they be Apples or Pears. Then, again, when the fruit is all stored the inspection of the fruit room is a great source of enjoyment when the quality is what it should be.

Alluding more particularly to the recent show, it has been stated the Apples showed to the best advantage in point of numbers, whilst the Kent exhibitors still carried off the greater number of the premier awards. Some of the exhibits, however, from other parts of the country beat the best of the Kent productions in the single dish classes for Apples. In the Pear classes, the best collection came out of Sussex in the large class, whilst from other counties came those who also vanquished the Kent men, the same results obtaining in the single dish classes. For Plums the Kentish growers were beaten most decisively, the prizes in these classes being well distributed.

The arrangement of the exhibits was excellent, the remarks made on this point after last year's exhibition being again fully sustained. The one regrettable thought running through the minds of very many exhibitors was that this show is probably the last over which Mr. A. F. Barron will preside.

### COLLECTIONS OF FRUIT.

For a collection of twelve dishes of ripe fruit, not less than six kinds nor more than two varieties of a kind, there were three competitors, Mr. McIndoe (gardener to Sir Joseph Pease, Guisborough) winning the premier prize with an admirable collection considering the lateness of the season. This collection comprised a well-ripened bunch of Bananas of excellent colour, two fairly good dishes of Grapes (Gros Maroc and Foster's Seedling), with fine dishes of Bryanston Gage and yellow Magnum Bonum Plums, extra good dishes of Exquisite and Golden Eagle Peaches, Doyenné Boussoch and Pitmaston Duchesse Pears, with Gascoigne's Scarlet Seedling Apple, Figs, and a Melon. Mr. Gleeson (gardener to Mr. C. E. Keyser) was a remarkably close second, having a grand Ripley Queen Pine weighing 6 lbs. 10 oz., highly coloured Muscat Grapes and good Black Alicante, with specially good Sea Eagle Peaches and Victoria Nectarines, as well as excellent Figs and Pears. Mr. Goodacre (gardener to the Earl of Harrington, Elvaston Castle), who came in third, had a collection below his usual standard—two quite small Pines, giving but a poor idea of British Pine culture. For

a collection of eight kinds of fruit, Mr. Reynolds (gardener to Messrs. de Rothschild, Gunnersbury Park) was placed first with an admirable collection, the fruits being very fresh and none too ripe. This comprised an extra fine Melon, Sutton's A1, well-coloured Muscat and Gros Maroc Grapes (the latter with large berries), Sea Eagle and Thames Bank Peaches, both well coloured, a fine dish of Ribston Pippin Apples, good Pine-apple Nectarines and Coe's Golden Drop Plums. Mr. F. Harris (gardener to Lady Henry Semersset, Eastnor Castle) came in a close second, having the same sorts of Grapes as in the previous case, two fine dishes of Peaches (Lord Palmerston and Gladstone), also two of Nectarines Pine-apple and Albert Victor, with a fine dish of Coe's Golden Drop Plums.

### GRAPE CLASSES.

These were not on the whole so good as last year. This was most noticeable in the Muscats, Madresfield Court and other fine Grapes, as Duke of Buccleuch. There was, on the other hand, an absence of badly-coloured exhibits in both black and white kinds. The average size of the bunches, taken as a whole, was less than usual.

Mr. Goodacre showed strongly in the class for six kinds of Grapes, two bunches of each, the dozen bunches making a fine display. The sorts were Barbarossa, extra good, close shapely clusters, with large berries well coloured; Muscat of Alexandria, remarkably fine in colour and in bunch; Gros Colman, with extra large and beautifully finished berries, and the bunches of good proportions; Lady Downe's, well shouldered, a feature not often seen, the colour very dense and berries large; Mrs. Pearson, also excellent and clear in the berries, a fine counterpart to the preceding, with Alicante of good average quality. Mr. Reynolds, who followed, had a very even and well-finished exhibit, in which Chasselas Napoleon stood out quite distinct, very large, clear in the berry, conforming in colour more nearly to the definition "white" than any other Grape. Mr. Taylor (gardener to Mr. C. Bayer, Forest Hill) also showed strongly in this class, his finest being Madresfield Court (the best in the show), Gros Maroc and Alicante, both extra good in every sense.

For three varieties in half-a-dozen bunches, the competition was not nearly so good as last year; the prize-winner may consider himself fortunate in being awarded that position, the second being decidedly the better exhibit. Mr. P. T. Phillips, Whitfield (gardener Mr. Belcher), was first, the sorts being Alicante, one large and one small bunch, fine in berry; Gros Colman, extra fine bunches and immense berries; and Lady Downe's, well coloured and even, but with one bunch rubbed in transit. Mr. C. J. Massey, Garleston (gardener, Mr. Day), was placed second, his exhibit indicating high-class quality, Mrs. Pince and Madresfield Court both being good—the whole a very even exhibit.

With Black Hamburg, Mr. Taylor was first, showing this standard variety better than anyone else in the show, the colour being still good. Mr. Mitchell, Chilworth Manor, Romsey, was second. With Madresfield Court, Mr. Day was first, the bunches large and tapering and the colour good, but the berries small. Mr. Taylor followed very closely, the berries being the finer of the two. For Gros Colman, or Gros Maroc, Mr. Gibson (gardener to Earl Cowley, Chippenham) was a good first with the latter variety in its best and most characteristic style, with dense bloom and immense berries. Mr. Day, who followed, had equally good bunches, but smaller berries of more oval shape. Black Alicante was a very strong class, the majority of the exhibits being well finished. Mr. Reynolds was first with medium-sized, well-coloured bunches and berries above the average. Mr. Tate, Streatham (gardener, Mr. Howe), who was second, had much larger bunches, but with smaller berries. For any other black Grape, Mr. Mitchell was decidedly first with very handsome bunches of Mrs. Pince, of extra fine finish, the deepest blue-black, and the bunches dense and of good proportions. Mr.

Serese-Diekens, Coolhurst, Horsham (gardener, Mr. Kemp), was second, with Lady Downe's of more than average quality in every point.

With Muscat of Alexandria, Mr. d'Arcy, Stanmore (gardener, Mr. Tidy), was first, the colour, a rich amber, being the strongest point, although the bunches were of good size and the berries large. Alderman Chaffin, Bath (gardener, Mr. Taylor), was a close second, the bunches being much finer, but the colour a shade less good. These two exhibits indicated, in our opinion, two distinct forms. For any other white Grape, Mr. Taylor, Forest Hill, was first with Buckland Sweetwater, unusually fine in berry, very clear and transparent in colour, and the bunches large. Mr. Reynolds was second with Chasselas Napoleon, again excellent. The next award gave cause for much comment, it going to Buckland Sweetwater of hardly moderate quality, whilst some splendid bunches of Mrs. Pearson were entirely passed over, these being very large in bunch and berry. Figs were at a discount, no prizes being awarded, the same remark applying to Vines in pots.

Tomatoes were staged in large numbers and of the highest quality, Mr. Howe being first with four varieties, all bearing the stamp of Perfection, the standard exhibition Tomato under whatever name it be shown; the sorts were Sutton's Perfection, Frogmore Selected, a fine form and very solid, Trophy, and Haekwood Park. Mr. Ryder, Orpington, Kent, was second, his best being Mayflower and Duke of York, both extra fine. The best single dish was found in Polegate, the fruits extra fine and weighty, from Mr. Helman, gardener to Viscount Gage, Firlie Park, Sussex, Mr. Sanders, Halton, being second, also with large fruit (Ham Green Favourite), well ripened. For six clusters of Tomatoes in one variety only, Mr. J. Gore, Polegate, Sussex, was a comparatively easy first with Polegate, a form to all appearance of Perfection, the clusters being both heavy and well ripened, the average number of fruits to a cluster being between five and six. Mr. Wells, Bexley, was second, with the Old Red Improved, both good and heavy.

For a "collection of hardy fruit grown partly or entirely under glass to illustrate orchard house culture," the first prize was awarded to a collection of over sixty dishes of the best kinds known of Apples and Pears, with Plums, Peaches, and Nectarines, the entire collection showing but little affinity to orchard house fruit, not being so bright in colour even as many exhibits of similar fruits grown entirely outside, and singularly lacking in that clearness of skin and rich colouring indicative of such fruits grown under glass (the number of dishes evidently told). Mr. Martin Smith, Hayes (common gardener, Mr. Blick) was the fortunate winner of the first prize, the best dishes being, of Plums, Grand Duke, extra fine; Reine Claude de Bavay, also good and of rich colour; and Monarch, of extra size and with a deep bloom. The best Nectarines were Pineapple and Victoria, and the best Peaches, Sea Eagle and The Nectarine Peach, with good fruits of Pears, the finest being Doyenné du Comice, Magnate, Beurré Diel, Uvedale's St. Germain (why grow this Pear under these conditions?), Pitmaston Duchess, Princess, Conference, extra good, Durondeau, the same, and Beurré Hardy, with Marie Louise, Souvenir du Congrès, Louise Bonne, Emile d'Heyst, and Fondante d'Automne; whilst of Apples, the best were Emperor Alexander, Blenheim Orange (?), Ecklinville, and Cox's Orange Pippin. Mr. Potter, gardener to Sir Mark Collett, who was last year's first prize-winner, came in for the second award on this occasion. This exhibit, although of smaller extent, clearly indicated orchard house culture. The best dishes here were, of Plums, Grand Duke, fine; Pond's Seedling, clear; Monarch, Coe's Golden Drop, Green Gage, Kirke's and Ickworth; of Pears, Souvenir du Congrès, Beurré Baltet père, Marie Louise d'Uccle, Triomphe de Vienne, extra fine and clear, Doyenne Boussoch, Durondeau, Duchesse d'Angoulême, Pitmaston Duchess, General Todtleben and Beurré Bachelier; of Apples, Jefferson

and Melon, both very clear in the skin; Peasgood's Nonsuch and Hoary Morning, both alike good; Fern's Pippin, Wealthy, Belle Dubois, and Lord Suffield. Mr. McIndoe, who followed, had also chiefly orchard-grown examples of high class quality, Plums, Apricots and Peaches being strong points.

#### NURSERYMEN'S CLASSES ONLY.

The competitors in these classes were very highly favoured in one respect, viz., the only two gold medals offered in the entire schedule were to be won here, but, on the other hand, no minor award was offered in either class. This fact must, we think, have deterred some growers from competing. The way in which these several classes were specified and grouped afforded a wide scope for variety in arrangement. This the exhibitors took advantage of in a most effective manner, but more than one clearly transgressed the resolution of the fruit committee that no duplicate dishes should be staged in any one exhibit. This should not on any account be allowed, nor is it fair to those who comply with the regulations laid down. Be the fruit ever so good, it is not desirable to copy the fruiterer's-shop element.

For a collection of fruit trees in pots, Messrs. Rivers and Son staged a magnificent exhibit in every sense worthy of their reputation as the pioneers of orchard house culture in this country. It is doubtful if this firm ever made such a splendid cultural display in this particular branch before. It was both comprehensive in character and abundant in variety. In the centre of the group was a fine example of Salway Peach, bearing when it left the nursery some eighty fruits, some of which were shaken off in transit. Apples were represented by grand fruits of Cox's Orange Pippin, rich yellow in colour; Peasgood's Nonsuch, the fruits of immense size and very clear; Gascogne's Seedling, very bright and handsome, and Wagener, a comparatively unknown Apple. With these were beautiful examples of Crabs, which as decorative trees were ideals of such. Pears were also of first-class quality, the most noticeable of these being Doyenné du Comice, Conference, Louise Bonne, Vicar of Winkfield and others. Vines Golden Queen, Black Alicante, Directeur Tisserand and White Tokay, all had heavy crops of well finished Grapes. Gathered fruits of various kinds clearly indicating orchard-house treatment were also included, but these were "not to be taken into account by the judges." Why not? The gold medal of the society was most deservedly awarded.

For a collection of hardy fruit grown partly or entirely under glass to illustrate orchard-house culture, Messrs. Bunyard came out victorious with grand examples of their Kentish viceroy fruit, the arrangement of which was very tasteful and effective. This exhibit comprised amongst other fine dishes the following: Of Pears, Souvenir du Congrès, Durondeau, Doyenné Boussoch, Dr. Jules Guyot (a handsome Pear) and Beurré Mortilet; of Apples, Bietingheimer Red (very fine), Ribbed Greening, Blenheim Orange, Ribston Pippin (extra fine), Alexander, Washington, Rosemary Russet and Ecklinville; and of Peaches, Sea Eagle and Princess of Wales, with Appley Towers Grape, Plums and Figs, the whole of high class quality. The silver-gilt medal was awarded this exhibit.

Messrs. Bunyard and Co. were also winners in the following class for a collection of hardy fruits of not more than 100 distinct varieties grown in the open, the gold medal in this instance being the well merited award. In such a large display as this, only the names of the very finest can be given. There were of Apples, Mère de Ménage, Queen Caroline, Golden Spire, Ecklinville, Lord Suffield, Pott's Seedling, Tower of Glamis, Mrs. Barron, and Bismarck; and of Pears, Pitmaston Duchess, Souvenir du Congrès, Gilgil, Fondante de Thirriott, Williams' Bon Chrétien, and Dr. Jules Guyot, very fine; and Figs in the best varieties. Grapes and other hardy fruits were included. In the smaller class for fifty varieties under the same conditions, Mr. H. Berwick, Sidmouth, was the

winner of the silver-gilt medal; this collection comprised most admirable examples of high-class fruit, the entire arrangement being most effective. The best kinds here shown were of Apples, Peasgood's, Emperor Alexander, Cellini Pippin, Blenheim, Worcester Pearmain, and The Queen; of Pears, Beurré Clairegeau, Grosse Calebasse, Marie Louise, Souvenir du Congrès, and Maréchal de la Cour; of Plums, Grand Duke, Coe's Golden Drop, and Reine Claude de Bavay, with Quince, Medlars, Figs, and Cherries. For fifty distinct varieties of Pears in baskets or dishes, Mr. Watkins, of Pomona Farm, Hereford, was awarded the silver-gilt medal. A few of his best dishes, all of which were deserving of mention, were those of Marie Benoist, Clapp's Favourite, Beurré de Capiaumont, Fondante d'Automne, Pitmaston Duchess, Beurré d'Amanlis, and Marie Louise. This was a very instructive and beautiful display of Pear culture, and highly creditable to this well-known cultivator. The remaining award in this division again fell to the lot of Messrs. Bunyard and Co., who thus won three of the six medals awarded. This was for a collection of not more than fifty distinct varieties of Apples grown in the open air, the silver-gilt medal again being the award. The finest in this, a very fine exhibit, were Bismarck, Grenadier, Cox's Pomona, Royal Jubilee, Mrs. Barron, Golden Noble, New Hawthornden, Striped Beaufin, Blenheim Orange, The Queen, and Lord Grosvenor, the whole forming a most imposing display of the best kinds.

#### FRUITS GROWN IN THE OPEN AIR.

In this division were some of the finest fruits that could possibly be staged. They did not perhaps equal in size some of those in the single dish classes, but there were good quality and finish in nearly all the collections. The first prize was awarded to Mr. G. Woodward, Barham Court, Maidstone, for eighteen dishes (twelve cooking and six dessert), and a splendid lot was staged. Peasgood's Nonsuch, Lord Derby, Stone's, Gascogne's Scarlet, Washington, Belle Pontoise and Tyler's Kernel were very fine. Of the dessert kinds, Ribston, Cox's Orange, Baumann's Red Winter Reinette and Cornish Aromatic were remarkable for their splendid colour. Mr. Geo. Goldsmith, Leonardlee, Horsham, was a good second, and had some very fine dishes—Emperor Alexander, Lord Derby, Mère de Ménage, Cox's Pomona, Cellini Pippin (a splendid dish). The Queen (specially fine), Cox's Orange and Ribston being good. In the next class the competition was much stronger, no less than fourteen lots being staged, and though the fruits were little inferior in quality, these collections were much admired. Mr. T. W. Startop, Maidstone, was first. In his lot were splendid Warner's King, Lord Derby and Gascogne's Scarlet, the last named grandly coloured. Cox's Orange Pippin, Ribston Pippin and Baumann's Red Reinette were also good. Mr. A. T. Killick, Maidstone, was a good second, having several of the varieties named above in his collection. In the class for nine dishes (six cooking and three dessert) there were no less than sixteen competitors, Mr. Turton, Maiden Erleigh, being first with fine fruits of Loddington Seedling, Emperor Alexander, Cox's Pomona, Peasgood's Nonsuch, Warner's King and Mère de Ménage, with grand dessert fruits, the varieties being King of Pippins, Ribston Pippin and Cox's Orange. The second place was taken by Mr. S. H. Goodwin, Mereworth, who had very fine Peasgood's Nonsuch, Blenheim Orange and Yorkshire Beauty. The competition was equally good for the best six dishes of cooking Apples. Mr. Woodward was a good first, staging fruit of immense size, weight, and rich colour. Mr. S. T. Wright, Glewston Court, Herefordshire came second with fruit little inferior to the above. He had grand examples of Warner's King, Peasgood's Nonsuch, Lane's Prince Albert, and Ecklinville. Thirteen collections were staged. In the class for three dishes there were twelve competitors, Mr. R. C. Sanders, Halton, Tring, being first with good

fruits of The Queen and Emperor Alexander. In the class for six dishes of dessert Apples there were thirteen competitors. The Ribston and Cox's Pippin were remarkable for size, colour, and good shape. Rarely has such fruit and in such quantity been staged. The premier award again went to Kent, Mr. Woodward securing the same with grand examples of Washington splendidly coloured, Ribston Pippin, Red Reinette, Cox's Orange, Lady Sudeley, and Calville Rouge Précoce, Mr. G. Goldsmith being a close second with, amongst others, very good Gravenstein, Egremont Russet and Adams' Pearmain. No less than thirteen competed for the three dishes of dessert. Mr. A. Kemp, Horsham, was first with nice fruits of American Mother, Ribston, and Cox's Orange. The classes for Pears created much interest, and though the quality was good and the fruits large enough for all purposes, these fruits, as regards size, did not compare favourably with Apples in the collection. Some grand fruits were staged, and there was more colour than last year. The prizes in this the large class went to Kent and Herefordshire. For twelve dishes of dessert Pears Mr. G. Goldsmith led with really superb fruits of Pitmaston Duchess, Duchesse d'Angoulême, finely shaped fruits of the newer Princess, Beurré Diel, Marie Louise d'Uccle, Louise Bonne of Jersey, Gen. Todtleben, Durondeau, Beurré Clairgeau, Flemish Beauty, Beurré Superfin, Doyenné du Comice, and Marechal de la Cour. Mr. Woodward had smaller fruits in his second prize lot, but all really excellent in other respects. For twelve dessert Pears there was more competition, eight lots being staged. Mr. Cotterill, Tonbridge, was first, having fine Beurré Clairgeau, B. Bosc, B. Superfin, B. Rance, Pitmaston Duchess and Duchesse d'Angoulême. Mr. W. Pragnell was second with equally good fruits, but not equal in colour. For nine dishes there were seven competitors, Mr. J. Gibson, Chippenham, taking the premier award with nice fruit, having highly-coloured B. Clairgeau, fine Triomphe de Vienne and Alexandre Lambre; Mr. Burton was second, having fine Marie Louise and Flemish Beauty. In the class for six dishes there were eight competitors, Mr. Bannister leading with good dishes of Pitmaston, Conseiller de la Cour (very fine) and Durondeau. This exhibit was noticeable for the fine colour of the fruits, Mr. Slegrove, Reigate, being second. For three dishes there were eight lots, Mr. Fennell, Tonbridge, being first, having fine Margaret Marillat; second, Mr. G. H. Field, Sevenoaks. Stewing Pears were numerous and large; some appeared to have been grown under glass. For three dishes Mr. Woodward had very heavy fruits of Catillac, Vicar of Winkfield and General Todtleben; second, Mr. Cotterill. For a single dish Mr. Masterman was first with Uvedale's St. Germain.

Peaches, for which there were only two classes, were well shown. For three varieties, Mr. Woodward secured the premier award with grand fruits of Sea Eagle, Princess of Wales and Nectarine Peach, Mr. Herrin, Dropmore, being a close second with a trifle smaller fruits, but of fine colour. For the single dish, Mr. Richards, Streatham, was first with Barrington, a grand late variety; second, Mr. Markham, Mereworth. There was only one exhibitor of Nectarines, Mr. Goldsmith taking the prize for three dishes of medium-sized fruits not named.

Plums were plentiful and good considering the season. Mr. McIndoe was first for four dessert kinds with excellent fruits of Nonsuch, Golden Drop, Jefferson and Bryanston Green Gage; Mr. J. Day, Garliestown, being a close second with fine dishes of Reine Claude de Bavay and Lawson's Golden Gage. For one dish, Mr. Herrin was first with Golden Drop, Mr. Rickwood second. For four dishes of cooking Plums there was a good competition, Mr. Day being first with very fine Pond's Seedling, Goliath, Magnum Bonum, and Victoria, Mr. McIndoe being second with smaller fruits. For one dish, Messrs. Empson and Sanders took the awards in the order named, Monarch being staged. In the class for Gage Plums, Mr. Hill, Cambridge, was first with Reine Claude de

Bavay, Mr. McIndoe being second. Damsons and Prunes were shown largely, Mr. Fennell being first, having very large fruits of Cluster King Prune and the common variety, Mr. Killick being second. The first prize for Bullaces went to Mr. Tebbutt, Isleworth, for a large yellow variety, Mr. Wells, Bexley, being second. Some very fine Morello Cherries were staged, there being nine lots. Mr. Masterman was first. The prizes for Nuts of any kind did not bring many competitors, considering what a prolific season it is for most kinds. Mr. Turton was first. In these cases they exceeded the number allowed in schedule, which should be strictly adhered to. There were no less than thirteen lots of Quinces staged, mostly good and well coloured, Mr. W. Mitchell, Romsey, Hants, being first. There were only twelve classes this year for dessert Apples, this doubtless admitting of the cream being staged. For the best dish of the following varieties we give a brief list, Mr. Turton being first for Adams' Pearmain and Mr. McKenzie second. For Cox's Orange Pippin there were forty-five competitors, showing the value of this good old variety, Messrs. Turton and Wright being successful with very fine fruits. King of the Pippins was equally numerous, Mr. Wyatt, Hatton, Hounslow, and Mr. Turner, Brighton, taking the awards. Mannington Pearmain was less numerous, Mr. Turton being first and Mr. Potter second. Margil was good, Messrs. Spencer and Wyatt taking the awards. Seven competed for American Mother, Messrs. Mackenzie and Spencer being successful. Reinette du Canada was good, Mr. Woodward being an easy first with large fruits, and Mr. Munro, Beckenham, second. For Ribston Pippin thirty-nine competitors entered, some remarkable specimens being staged, Mr. Ocock, Rudgwick, being first with a splendid dish. Six entered for Rosemary Russet, Messrs. L. Cavanagh, Roehampton, and T. Turton being successful. For Scarlet Nonpareil eight lots were staged, Messrs. Empson and McKenzie being first and second in the order named. For Worcester Pearmain, Messrs. Wakefield, and Killick, Maidstone, were the prize-takers. For any other variety thirty lots were staged, Mr. Mackenzie winning easily with a grand dish of a new Apple named St. Edmund, a beautiful fruit with a russet skin, and said to be a good keeper.

Cooking Apples were shown well and of large size. In the single dish classes for Alfriston, Messrs. Mackenzie and Woodward were the prize-takers. Bismarck was shown by twelve exhibitors, Messrs. Mackenzie and Woodward heading the list. Blenheim Orange was represented by twenty-nine dishes, Mr. Ross, Newbury, and Mr. Killick being successful. For Bramley's Seedling twelve competed, Messrs. Killick and Woodward taking the awards. Cellini was numerous and beautifully coloured, Messrs. Killick and Mackenzie being the successful exhibitors. Cox's Pomona was shown by twenty-three competitors, Messrs. Ross and Goodwin being successful. Duchesse of Oldenburg was good, Messrs. Wright and Goodwin being the winners. For Wellington the awards were not creditable to the judges, who awarded the first prize to a dish of Hawthornden. This was reversed later in the day, Messrs. Ridgwell and Ross being successful with grand fruits. Mr. Mackenzie headed the class for Ecklinville, twenty-three lots being staged. Emperor Alexander was put up by twenty exhibitors, enormous fruits being staged, Messrs. Mackenzie and Buxton, Chertsey, being the winners. The same remarks apply to Gascoigne's Scarlet, Messrs. Mackenzie and Goldsmith securing the awards. Golden Noble was perfect, Messrs. Woodward and Mackenzie taking the awards. Hawthornden was superb, Mr. Mackenzie being first. Lane's Prince Albert was equally good, Mr. Ross having a grand dish; Mr. Prinsep, Buxted Park, second. Lord Derby was staged by twenty-two competitors, Messrs. Goldsmith and Woodward receiving the awards. Lord Suffield was very fine, Messrs. Turton and Mackenzie leading. Mère de Ménage was a grand class, colour being superb, Messrs. Mackenzie and

Spencer being successful. Northern Greening was larger than usual, Messrs. Prinsep and Jones, Carshalton, being successful. For Newton Wonder there was a special prize, but not many competed, Messrs. Goldsmith and Harris, Croydon, taking the awards. Peasgood's Nonsuch brought out nineteen lots, all excellent, Messrs. Mackenzie and Woodward dividing the prizes. Stirling Castle was largely shown, Mr. Ross having a grand dish. Tower of Glamis was very fine, Messrs. Woodward and Ross taking the awards. For Warner's King, Messrs. Mackenzie and Woodward were first and second. Any other variety brought forth twenty-nine competitors, Mr. Mackenzie being first with Belle Dubois, Mr. Woodward second.

Pears were very good and equally numerous. For the best Beurré Diel, Mr. Wythes, Syon, Brentford, was first, having fine fruits with clear skins. Beurré Hardy was very good, Messrs. Woodward and Prinsep being most successful. Beurré Superfin was not largely shown, Messrs. Woodward and Goldsmith dividing the awards. There were fifteen lots of Maréchal de la Cour, Messrs. Sanders and Herrin being most successful. For the newer Conference Mr. Woodward was placed first, but the second lot of Mr. Wythes' was superior, being better finished, clearer in the skin, and equally large. Judging certainly was erratic in some cases. Doyenné du Comice was a fine lot, Messrs. Goldsmith and Woodward having grand dishes. Messrs. Woodward and Goldsmith had the best Emile d'Heyst. The best Glou Morceau came from Mr. Goldsmith. Mr. Ross had the finest Josephine de Malines, and Mr. Goldsmith the best Louise Bonne of Jersey. Marie Louise was exceptionally fine, Messrs. Burton and Goldsmith having the leading dishes. The best Nouvelle Fulvie came from Mr. Wythes. Souvenir du Congrès from Mr. Thompson, Hounslow, was very fine. Thompson's was very fine from Mr. Goldsmith. For Winter Nelis, Messrs. Prinsep and Goldsmith had the awards for very fine examples.

#### DRIED FRUITS.

There was little competition in the classes for dried fruits, but Mr. Trotter, of Ledbury, was deservedly first in every class. In his collection he showed Plums, Cherries, Pears, and Apples, the latter in rings, whole and cored fruits. The other classes were Apples sliced one pound, Apples whole one pound, and the same amount of Plums and Cherries, also whole. This was a most attractive exhibit, and clearly showed that fruit growers might combine to preserve surplus fruit, and if of the same excellent quality as shown here there is no doubt it would find a ready market. Mr. B. W. Bull, of Billericay, showed in two of these classes and received second prizes.

In the class open to market growers only, for six varieties of hardy fruits grown in the open air, two gallons of each, Mr. S. H. Goodwin, of Mereworth, was first. He showed Apples Lady Heniker, Cox's Pomona, Stone's, Blenheim, Cox's Orange, and Doyenné du Comice Pear, all admirable and highly coloured samples of their kinds. Mr. G. Tebbutt, of Isleworth, was second, showing Apples, Pears, and Plums, two varieties of each.

In the packing classes, Mr. R. Grindrod, Whitfield, was first for a bushel of a cooking Apple and a half-bushel of a dessert kind. The fruits were packed in layers in baskets with a pad of wood wool and paper between each layer. The great advantage of this packing was that the quality of the fruit could be seen at a glance. The second prize went to Mr. Cotterill, gardener to Mr. W. Gear, Tonbridge. The best packed basket of Grapes came from Mr. C. Cooper, Sunninghill, Berks, whilst the second prize went to Mr. J. Gore, Polegate. Mr. Wells, gardener to Mr. F. J. Arbutnot, Bexley, was first for the best packed box of Peaches, Mr. Grindrod being second. For a similar exhibit of ripe Pears, Mr. Wells was again first and Mr. A. Pentney, Isleworth, second.

#### MISCELLANEOUS.

The miscellaneous exhibits made up a large portion of the show, and the collections of fruit

from some of the trade growers were very fine indeed, as also was that staged by Mr. Thomas from the Royal Gardens, Frogmore, which filled a large table and was admirably set up. The finest Apples were Ribston, Gloria Mundi, Wellington, Annie Elizabeth, Stone's, Emperor Alexander, Blenheim, Cox's Orange, Warner's King, Schoolmaster, Royal Russet, The Queen, Mère de Ménage and Peasgood's Nonsuch. The following Pears were also very fine: Louise Bonne of Jersey, Triomphe de Vienne, Marie Louise, Duchesse d'Angoulême, Pitmaston Duchess and Brockworth Park. A very large display was made by Messrs. J. Veitch and Sons, their Apples especially being fine. The best were Cox's Orange, Potts' Seedling, Ribston, Tyler's Kernel, Cellini, Blenheim, Peasgood's Nonsuch, Mère de Ménage, Fearn's, Bismarck, Gascoigne's, Tower of Glamis, Belle de Boskoop (a fine Apple like a long Ribston), King Harry, Bramley's, Lane's, Lamb Abbey Pearmain and Lady Lennox, a fine keeping Apple from the midlands. Among Pears, Marie Louise, Triomphe de Vienne, General Todtleben, Doyenné du Comice, Flemish Beauty, Soldat Laboureur, Beurré Bachelier, Fertility, Sénateur Vaisse and Louise Bonne of Jersey were all noteworthy. Other fruits well shown in this lot were Raspberry Superlative, proving it to be a good successional fruit; Plums in variety, Currant White Grape, King of the Damsons, a very fine fruited kind, Alpine Strawberries and the cut-leaved Blackberry. The new *Physalis Franchetti* was also well shown in this collection, which consisted of 100 dishes of Apples, the same number of Pears, and fifty of various fruits. Messrs. Charles Lee and Son, of Hammermith, showed a meritorious lot of Apples and Pears, their best dishes of Apples being Peasgood's, Lord Suffield, Cellini, Potts' Seedling, American Mother, Betty Geeson, Lane's Prince Albert, Warner's King, Golden Spire, Blenheim, Manks Codlin, Reinette du Canada, Stirling Castle, Mère de Ménage, and Wellington. The finest Pears were Marie Louise, Hacon's Incomparable, Beurré d'Anjou, Souvenir du Congrès, Fondante d'Automne, Louise Bonne of Jersey, Pitmaston Duchess, Brockworth Park, Durondeau, Olivier des Serres, and the new Princess. From Gunnersbury Park Gardens Mr. G. Reynolds showed a smaller, but first rate collection, Emperor Alexander, Sandringham, Gloria Mundi, Gascoigne's Scarlet, Beauty of Kent, Alfriston, Ribston, Annie Elizabeth, and Cox's Orange being fine among the Apples, and Pitmaston Duchess, Brockworth Park, Urbaniste, Durondeau, Doyenné du Comice, and Knight's Monarch the best Pears. A very interesting collection of Pears, in all seventy-five varieties, was that shown by Mr. Barron from the society's gardens at Chiswick. The best dishes were those of Conference, Jersey Gratioli, Mme. Andre Leroy, Marie Louise and Marie Louise d'Uccle, Louise Bonne of Jersey, Winter Nelis, Doyenné Boussoch, Beurré Diel, Bellissime d'Hiver, Souvenir du Congrès, Des deux Sœurs, Col. Clarke's Seedling, Emile d'Heyst, Doyenné du Comice, Thompson's, Pitmaston Duchess, Zephirin Gregoire, Maréchal de la Cour, and Comte de Lamy. Messrs. J. Cheal and Sons exhibited Apples and Pears very fine indeed, large size and good colour especially characterising their Apples. Bismarck was well and largely shown, and besides the gathered fruits two year old trees were shown bearing fine fruits and testifying to the early fruitfulness of the kind. The Queen, Blenheim, Cox's Orange, highly coloured, Stirling Castle, Yorkshire Beauty, Lord Derby, Wellington, King of the Pippins, Frogmore Prolific, Hollandbury, and Loddington were all good; and in Pears, Beurré Niger, a large green Pear, in shape resembling Easter Beurré, was a prominent kind, whilst Brockworth Park, Princess, Van Mons Leon Leclerc, and Louise Bonne were all noteworthy for size and colour. Messrs. Laing and Sons, of Forest Hill, were large exhibitors of Apples and Pears of fine size and high quality, Stirling Castle, Lord Suffield, Bess Pool, Cellini, King of the Pippins, the Queen, Annie Elizabeth, Sandringham, Hanwell Souring, a fine dish of

this long keeping kind, Cornish Gillyflower, Alfriston, Cox's Orange, very good, Ribston and Fearn's being noteworthy. The best Pears were Duchesse d'Angoulême, Pitmaston Duchess, Brockworth Park, Louise Bonne of Jersey, Glou Morceau, Passe Crassane, Marie Louise, and Nouveau Poiteau. Some well-fruited orchard house trees were also shown in this collection. Messrs. Spooner, of Hounslow, showed a good lot of Apples and Pears, their finest being Stirling Castle, Warner's King, Stone's, Cellini, Wellington, Alfriston, Golden Noble, and Lord Derby, with Windsor, Pitmaston Duchess, Marie Louise, and Souvenir du Congrès Pears. Messrs. Peed and Sons, of Norwood, made a meritorious display, several kinds being well shown, notably Bismarck, Old Hawthornden, Stirling Castle, Cox's Pomona, Cellini and Ribston Apples, and Pears Flemish Beauty, Margaret Marillat and Pitmaston Duchess. A dish of Nectarine Humboldt was also shown, the fruits, which were of medium size and good, having been gathered from a standard tree growing in the open air. Messrs. W. Paul and Sons, of Waltham Cross, showed well-fruited orchard house trees and an admirable lot of outdoor fruit, chiefly Apples. Some good Pears were shown besides. The great display of Tomatoes made by Messrs. Sutton and Sons, of Reading, proved how favourable the present season has been to this fruit, as the whole of that shown was grown and ripened out of doors. The fruits hung upon the stems like ropes of Onions. In all, thirty-seven varieties were shown, representing every type of this fruit, from the little cluster and Pear-shaped kinds to the large solid fruits that individually turn the scale at a pound. Earliest of All was remarkably profuse in cropping, whilst in Best of All, Maincrop and Perfection we have a trio of the best kinds. Golden Perfection is quite a counterpart of the older Scarlet Perfection, and has a large solid fruit. Others extra fine were Tender and True, Sunbeam, Golden Nugget and Frogmore Selected.

The new Duke of York Tomato was admirably shown by Messrs. Fellows and Ryder, of Orpington, about twenty dishes, each having nine fruits, all fine solid examples of this grand variety. A few miscellaneous floral exhibits gave a welcome variation and a charming finish to the show. Mr. H. J. Jones, of Lewisham, arranged a large and graceful group of flowering and fine-foliaged plants, Chrysanthemums and Begonias predominating. Messrs. Laing and Sons, of Forest Hill, also had a prominent and beautiful group of Palms, Crotons, Caladiums, Dracenas and Begonia Rex in a number of lovely forms all tastefully arranged. Roses in large clusters, fine and fresh, were extensively shown by Messrs. W. Paul and Son, of Waltham Cross, showing what a glorious autumnal bloom Roses have given this year. Mr. T. S. Ware had a large group of double-flowered Begonias, and he also made a rich display of Dahlias in all sections, while another fine group of this flower came from Messrs. Cheal and Sons, Crawley. Hardy flowers were represented by two noble groups. That from Mr. M. Prichard was a gay mass of Starworts, perennial Sunflowers and Phloxes, whilst an equally fine lot from Mr. Ladhams had, in addition to the above-named flowers, *Helenium striatum* in beautiful colour, *Lobelia fulgens* in variety, and Ernest Ladhams Pink in quantity. Messrs. W. Cutbush and Son showed large and heavy fruits of Tomato Polegate and a beautiful lot of a very charming new single Dahlia, which we have noted elsewhere. Messrs. Veitch showed *Magnolia Watsoni* (second blooms) and *Berberis Thunbergi* in brilliant colour with its autumn-tinted leaves and scarlet berries.

**National Chrysanthemum Society.**—A meeting of the general committee of this society was held on Monday evening last at Anderson's Hotel, Fleet Street, when Mr. B. Wynne occupied the chair. After the minutes of the previous meeting were read and confirmed, the secretary read a form of special circular to be sent out re-

specting the society's jubilee next year, and also stated that the schedule was in course of preparation. Already several handsome prizes have been offered for competition next year, and it is hoped that there will be a heavy response to the appeal for special prizes and funds to enable the jubilee celebration to be carried out in a fitting manner. Some colonial correspondence was read, including letters from New Zealand, South Africa and Australia. A pattern small silver medal was submitted for approval, and it is proposed that it shall rank between the society's bronze medal and the silver one now in use. It was announced that prize money to the value of £11 10s. was awarded at the recent September show for early Chrysanthemums, and two medals, viz., a silver one for a group exhibited by Mr. Davis and a bronze one to Mr. Shaw, were confirmed on the judges' recommendation. A rough financial statement was submitted, showing the receipt of income amounting to £156 16s. 11d. to the present date. Fifteen new members were elected and two Fellows, and the Hertford Horticultural Society was admitted in affiliation.

## OBITUARY.

MR. PETER GRIEVE.

I AM sorry to record the death of this well-known gardener on Thursday, September 26, at the age of 83. For several years Mr. Grieve had been known to suffer from heart disease. Fond as he was, when well, of sending notes to the gardening papers, he had almost left them off of late in deference to his health. His love of gardening continued as strong as ever till the last, and few have been able to accomplish more for the cause than Mr. Grieve. It has been my privilege to live near him and work with him in many things horticultural for nearly fifty years, and during that long period I always found him a firm friend. As a cultivator, a propagator, and landscape gardener, Mr. Grieve displayed great ability and taste. Culford Gardens, which he formed and superintended for nearly thirty-five years, were, and are, his highest testimonial. The noble Yew hedges that enclose the quarters of the kitchen garden, which he planned and planted, show the regularity and boldness of his designs. The flower garden and other flower beds and borders were models of form and colour for years. The tricolor, bicolor, and bronze Pelargoniums raised by him, and which were all the rage for years, were assuredly beautiful and popular in their time. Even so-called antic-colourists will admit that something was gained by taking the glare of Pelargoniums out of their flowers and painting it on their leaves. All this, and much more, Mr. Grieve did for the tricolor Pelargoniums. But the man was better than his work. A more genial friend and kinder neighbour none could desire. His widow survives him. His only daughter, Lucy Grieve, who raised the Pear bearing her name, died some years ago.

D. T. FISHER.

Which does mend Nature; change it rather; but  
THE ART ITSELF IS NATURE."—*Shakespeare.*

## ORCHARD AND FRUIT GARDEN.

## OUTDOOR GRAPES IN SURREY.

SEVERAL years ago there was a discussion in THE GARDEN with respect to the practicability of cultivating certain Grapes on open walls in the warmer districts of this country. I then stated that in former years this form of Grape culture was much practised in the south of England, and that in most years the fruit ripened well when the Vines got good cultivation. I mentioned that in my boyhood, cottages, farm buildings, and outbuildings on gentlemen's estates were in a general way clothed with Vines, carrying in ordinary years good crops of well-ripened berries. At the time the discussion took place I showed what had been written to some of the older inhabitants of the district, and they one and all assured me that I had in no sense exaggerated. I may be told that this is an exceptional season and that we are not likely to be often favoured with such abundant sunshine; but not so many years ago wet summers and cold autumns were more the exception than the rule, and a season so wanting in warmth that the berries were not sweet and pleasant to the taste was very rare indeed. If we could be favoured with a return of the old-fashioned summers, Grape culture on open walls would again become popular. To such an extent were outdoor Grapes grown in this part of Surrey at least, that even the roofs of many buildings and one-storied dwellings were covered with trellis-work, on which the Vines grew and fruited freely. I would ask your readers if it is likely that anyone would incur the expense of fixing up a substantial trellis unless assured that the fruit grown thereon would ripen. As a fact, I have seen bushels of black and white Grapes grown in this way, and very pretty these Vine-clad roofs looked, especially when loaded with ripe fruit. Of these trellised roofs not one that I knew of remains, and ninety-five per cent. of the Vines, that were a source of pride and frequently profit, have disappeared. Curiously enough, the decline in this form of hardy fruit culture commenced when bad times for the farmers set in, these being—as some of your readers may remember—heralded by a series of inclement seasons so wet and cold, that unripe corn stood at the foot of the Surrey hills in October and Couch Grass came halfway up the stalks thereof; in fact, our climate seemed all at once to change. The Vines were attacked by mildew, which never happened before, and many half a century old died right out. Cottagers and others had not the heart to plant young Vines, and so open-air Grape culture has almost died out.

With respect to the Grapes sent, I may say that they were sweet before this last spell of intense heat set in; they could have been eaten in the first week of September. Moreover, the Vine which produced them is on an east wall, not quite the best aspect for outdoor Grapes. Possibly we are nearing the end of the long cycle of more or less bad years, and may hope for more favourable conditions for hardy fruit generally. In two years out of three, Grapes have ripened on open walls, and the abundance of hardy fruit in gardens and orchards re-

minds one of the fruitful seasons of thirty years ago. As regards Grapes, times have changed, and the culture of home-grown fruit has increased to such an extent that well-flavoured Hamburgs are retailed at very low rates. The finest summer possible cannot make outdoor Grapes equal them, but they are at least as sweet and much more wholesome than the thick-skinned "grocer's grapes" that are consumed in quantity in this country. I am not sure that we have the most suitable kinds for open air. When in France I passed through my hands upwards of 400 varieties of outdoor Grapes, some of them very early and of tolerably good flavour, very much better in this respect than the common White and Black Cluster. Will not some reader of THE GARDEN having convenience give some of them a trial; they ought to be procurable from the French nurserymen, especially from those living in the south of France?

Buxton, Surrey.

J. CORNHILL.

**Open-air Figs.**—The kindly criticisms of Mr. D. T. Fish on the cultural notes on this fruit by "W. G. C." and myself are well worth noting, as they come from the pen of one the greater portion of whose life has been spent in a district celebrated for its luscious Figs. I am glad to find that the ideas of Mr. Fish and myself as to what constitutes the proper treatment for outdoor Figs are very similar, although we differ on a few minor points. I have seen the fishing-rod shoots of which he speaks, the result of planting in too rich a border and laying in too few growths, in which all the sap is concentrated, grossness following. I think, however, that while the knife ought to be used with discretion, the weakest growths should certainly be removed, their presence hindering the ingress of sun and air, and thus retarding the maturity of the fruit-bearing wood. The removal of this would not, I think, add perceptibly to the strength of or encourage grossness in well-managed trees whose roots are growing in a confined space and in a non-stimulating medium. The reason why I advised cutting this out in summer is that by so doing, the sun of July, August, and September can the better play on the shoots which are to remain intact, which cannot be the case if thinning is deferred till the autumn. In regard to protecting Figs in winter, I certainly think that where the trees are kept to the walls and a good thick covering of Bracken or straw, this being overlaid with old garden mats, can be given, almost any amount of frost could be excluded, the trees being again uncovered piecemeal in spring. It is useless, however, protecting one winter and not another, the reason being obvious. Trees that are allowed to grow in a free, unrestricted manner, as advised by Mr. Fish, and which is perhaps the most natural after all, cannot easily be protected, as all that could be done would be to distribute Bracken amongst the branches, as in the case of Tea Roses, and this, if frozen through after becoming saturated, would only make matters worse. As pointed out by Mr. Fish, those who contemplate planting Figs out of doors must guard against that too common and most fatal of all mistakes, a rich root-run. In reference to stopping the growths of Figs in summer, I quite agree with Mr. Fish that failure must follow such a practice, as the new growths resulting therefrom could never be expected to ripen in a climate like ours.—J. CRAWFORD.

— I think "D. T. F." (page 234) has scarcely understood my notes on the above in the way I intended. By a judicious system of pinching out the points of strong-growing shoots a decided check is given to Fig and other fruit trees, and I have never found any more force thrown into any part of the trees, except perhaps some of the weaker shoots have gained a little. I have brought many fruit trees of all kinds into a prolific habit by pinching out with the finger and thumb the points of the shoots and rubbing off

any others that were not required, thus avoiding the labour of root-pruning to bring the trees into a fruitful state. As regards "D. T. F.'s" experience in providing hard borders with plenty of lime refuse for Figs, I entirely agree with him.—W. G. C.

**The common Sweetwater Grape.**—Mr. Iggulden's remarks on the extreme usefulness of the Sweetwater Grape for out of doors and cool vineries recalls some curious incidents in my experience in which the common Sweetwater has been preferred to the choicest Muscats. A lady of title was the first to call my attention to what she called a serious fault in Muscat Grapes. She condemned them as too meaty and as needing too much eating to be pleasant. I was a young man at the time and had done my utmost to produce several houses of Muscats of the orthodox golden colour, one of them being Cannon Hall Muscat of the size of Green Gage Plums. I was next invited to an unique tasting match, consisting of Muscat of Alexandria, Cannon Hall Muscat, and Buckland Sweetwater. The first was compared to heavy port, the second to sound sherry, the third to sparkling champagne, and it must be admitted that there were some solid reasons for this classification. I have met with many instances since where the juicy Sweetwater has been preferred to fleshy Muscats by skilful physicians for their patients, or, failing the Sweetwater, very juicy Hamburgs have been preferred to Grapes that were dead ripe, or to any other more firm-fleshed or leathery-skinned kinds, black or white. In the case of invalids, of course, it is Grape juice rather than flesh that is desired. Could the fault of shy or irregular setting be cured in the Buckland Sweetwater, no Grape would equal it for sparkling juice at once light and refreshing. The Cannon Hall Muscat Grape is so much less solid than the Muscat of Alexandria, that some have thought it has a dash of the Buckland Sweetwater in its constitution, and this is further confirmed by its capricious setting.—D. T. F.

## VINES OUT OF DOORS.

I AM glad I found Mr. Iggulden (page 233) referring to the merits of hardy Grape Vines for the clothing of buildings and walls, and the providing of homes with refreshing and profitable fruit. Of late years there has been a set made against the cultivation of the Grape Vine in the open air. Hundreds of Vines up and down have been sacrificed to a change of fashion, and have had to give place to huge Plums or inflated Pitt-maston Duchess Pears.

Mr. Iggulden does well to start with a warning against strong shoots of young wood from 6 feet to 8 feet long in a single season. These may be allowable for furnishing high gable ends or other walls at the start, though even for this they are likely to give a wood-making tendency at the beginning rather than lead the Vines into fruitful ways from the first. But after the Vines are fairly established and have been pinched or pruned into fruit-bearing along their entire length, the less gross growth allowed the better. Mr. Iggulden, writing of the common Sweetwater or Royal Muscadine, recommends a distance of 3 feet between the bearing rods; this distance will seem extreme to most old-fashioned Grape growers. However, such extremes may be said to err, if at all, on the safe side. The greatest enemy of out of door Grapes has been overcrowding of branch, bunch and berry; the result has too often been to crush all three into a sort of entirely incompatible with profitable or creditable fruiting. Besides, the Royal Muscadine is one of the largest of hardy Grapes when well grown, and needs more room than the black and white Cluster, Miller's Burgundy, &c., which may be trained at one-third the distance between the bearing rods.

Of course, a good deal depends on the mode of pruning and training adopted. One of the best methods, as well as the oldest, is one or more leaders trained horizontally to the right and left, or the Vines may be planted as single, double, or multiple cordons at any desired distances, to

trained horizontally, vertically or diagonally. Anyhow, the fruiting branches should have sufficient space to utilise the sun and light of the locality to the utmost, and close pruning and severe thinning of shoots, bunches and berries are essential to the highest measure of success. I agree with most of what Mr. Iggulden says of the Black Hamburg in the open air, and yet very creditable samples of it are often ripened in the open air.

Should the present hot weather last, some fine samples in bunch and berry will soon be ripe at Bury St. Edmunds. But the Esperione, Cambridge Botanic Garden and Trentham Black are hardier black Grapes of good size for the open air than the Black Hamburg in the most favourable positions. The Black Sweetwater is about equal to the white, though not nearly so often met with. The Early Summer and Early Ascot Frontignans are among the finest flavoured Grapes out of doors and in. There are three more Frontignans—the White, the Black, the Grizzly—well worth growing in the open air. The whole of the Frontignans are of exquisite flavour. The chief weakness of Frontignans under glass is a tendency to shank or shrivel during the finishing stage, a failing they do not exhibit on warm walls in the open. The finest Grizzly Frontignans I have ever eaten—and the Grizzly well ripened is the king of them all for flavour—have been grown in the open air in East Anglia. D. T. F.

#### FRUIT PACKING AT THE CRYSTAL PALACE SHOW.

THE classes devoted to fruit packed for market were far better filled than was the case in 1894, and, taken as a whole, the packing was a decided advance upon the exhibits of the previous year. Class 124, for a bushel of cooking Apples and half a bushel of dessert Apples, was the least satisfactory of the four. Of the three entries, the first prize lots were packed in oblong covered hampers, lined first with brown and then with blue paper in the case of the cooking Apples, and with corrugated and blue paper in the dessert fruit, the Apples being in three layers and packed in too expensive wood-wool. The second prize was awarded to very good Apples packed in heavy and rough boxes with the lids nailed down, the fruit being packed in thin shavings of varicoloured tissue paper, which gave an unpleasant effect. The third prize went to Apples packed in paper shavings in the ordinary round bushel and half-bushel baskets. No attempt was made to pack in light, non-returnable, wire-hinged boxes, which can be got in quantity at a surprisingly cheap rate now-a-days.

For class 125, the best packed basket of Grapes, there were seven entries, four of which were packed in cross-handled baskets, two in oblong baskets with covers, and the remaining consignment in an unwieldy and lengthy covered hamper. With the exception of the last entry all the Grapes arrived in excellent condition. The three prizes all went to the cross-handled baskets, there being little or nothing to choose between the first and second prize lots, which were very near perfection. The third prize basket was of too flimsy construction, and an unnecessary wad of packing material was placed along the bottom with the intention of keeping the bases of the bunches steady. The prize baskets had split Bamboos bent over the fruit on each side of the handle, thus effectually preserving the Grapes from injury. The two covered hampers were well packed, but the shape of the package offers an inducement to let it down on an end or corner, which is impossible in the case of the cross-handled basket, and its extra weight is also a disadvantage.

For boxes of Peaches, class 126, there were seven entries, the first prize being adjudged to fruit wrapped in white tissue paper, the tops being left exposed, and packed in rather coarse, but springy, wood-wool, the price quoted for which, however, seemed exorbitant, and would be doubtless much reduced on taking any quantity.

The second prize went to a box in which the packing material was Moss, the individual fruits being wrapped three parts in blue and white tissue paper. The Moss had an unpleasing effect when compared with wood-wool, but one good box being disqualified for an informality in the manner of its arrival, and the third prize box, in which the packing material was best, "continental" wood-wool, containing a decayed fruit, the Moss-packed entry got into the prize list. In one elaborately got-up box each Peach was rolled in a strip of pink tissue paper and then in a long doubled strip of best white cotton-wool, trimmed level with the top of the fruit with scissors, over the whole several sheets of pink tissue paper folded, then a thick pad of the same cotton-wool. The effect was pretty, but it was considered altogether too expensive a method for profitable marketing. In one box the packing material was short grass. Curiously enough, in not a single case were paper shavings, the material advocated by Mr. Monro in his lecture on fruit-packing at the 1894 show, used.

In class 127, for a box of ripe Pears, there were eight entries, most of the boxes being tastefully packed. The first prize went to a box in which the same description of wood-wool that was employed in the packing of the first prize box of Peaches was used, the fruits being partially wrapped in white tissue paper. Second prize was awarded to a box packed with "continental" wood-wool, the Pears not being wrapped in paper. The third prize box had been carefully wrapped in brown paper; the hinged cover was also securely nailed down, the packing material used being the finest wood-wool, and each fruit partially wrapped in pink tissue paper. Of the remaining entries, two of the boxes were far too heavy, and two had covers nailed down. All but two in this class were packed with wood-wool, the two exceptions being packed with Moss.

The failures that last year's packing competition exhibited were this year conspicuously absent, the majority of the entries in classes 125, 126, 127 being well packed. The use of tissue paper for wrapping the fruit in is evidently on the increase, as is the employment of wood-wool as a packing material. It is well, however, to bear in mind that good judges are of opinion that the finest quality is apt, with pressure, to become too solid, and favour the coarser and more elastic kind, which is also the cheaper. The bad practice of nailing down the lids of the boxes is also apparently on the wane, only four out of the fifteen boxes being nailed down this year. S. W. F.

**Apple Ribston Pippin.**—Those who saw the splendid dishes of this variety at the Palace show will note that, in spite of the reports as to its failure to produce good crops in many parts of the country, it is even more popular now than ever. Doubtless much of the success with this variety is owing to more dwarf trees being grown. I have noted the importance of allowing a free growth, as I have seen trees that have been severely summer-pruned fail to crop freely. I find the best fruits are obtained from dwarf trees allowed to grow freely. Some old cordon trees given free play produce grand fruit and always bear. The fruits staged at the Palace were remarkable for size and colour, showing that a hot season is necessary to bring out to the full the good qualities of this old favourite.—S. H. B.

**Coarse Pears.**—Would it not be well to have a class for quality alone, not mere size? I noted at the recent great fruit show that nearly every collection contained Pitmaston Duchess. I admit it must be so. Judges do not go in for flavour or quality in these large collections; indeed I noticed some varieties only fit for stewing were given a prominent place. Most of the very large Pears are deficient in flavour, which should have first place. This is difficult, as everyone likes to grow large fruit. It is also necessary to show the public we can compete as regards size with foreign fruit. I do not find fault with those who grow large fruits, but ask the framers of schedules if it

is not possible to have one or two classes for what may be termed the best flavoured fruits, size in such being a minor point. I may be told that at the old Palace fruit shows there was a class on one or two occasions for fruits noted for flavour, but if I remember aright, these were cut by the judges, and when the visitors went round the cut Pears presented a sorry spectacle. I do not advise this cutting. Most persons who judge these fruits would know the flavour, so cutting would be unnecessary unless of a new kind, and then one fruit could be cut. To give variety, why not have a class for new Pears introduced during the last few years, the prizes being awarded for flavour, good cropping, and other qualities?—W. S. M.

**Apple St. Edmund.**—This was shown at the Crystal Palace by Mr. Mackenzie, Linton Park, Maidstone, and, like so many of the splendid Apples in the exhibition from the same locality, was much admired. It is above medium size, in shape somewhat similar to a good Ribston and dotted with russet on the sunny side. This variety will become a great favourite if it crops well and is of good flavour. Of course in all soils it may not do so well as in the favoured Maidstone soil. With this variety Mr. Mackenzie secured the prize for the best dessert Apple of any variety not mentioned in the schedule.—G. W.

**Pear Conference.**—This is well worth adding to the list of good varieties, having several good points in its favour, the chief being its handsome appearance and good cropping qualities, the flavour also being equal to that of many of our midseason varieties. This Pear was certificated at the conference at Chiswick in 1885. I have never seen it crop better than it has done this season. Its shape is pyriform, skin a deep green with russet, though this season I have fine fruits quite free from russet. I never saw the fruits so clean and smooth. The tree is a robust grower, doing well on the Quince and Pear stocks. It comes into use at the end of October or early in November, and when grown on a wall I should advise a cool aspect if the fruits are wanted late in the autumn.—G. W.

**Pear Le Lectier.**—This new Pear is valuable on account of its good qualities, and, what is better, it comes in at a season good Pears are none too plentiful. I do not think it is much grown in this country. I first saw it at one of our leading fruit nurseries as an orchard house tree in pots. I have grown it as a cordon on a warm wall and am very pleased with it. The fruits are large, handsome, and very richly flavoured. The tree is a great bearer on the Quince stock. For walls it is excellent, and being a late fruit, in season from January to March, makes it doubly valuable.—G. W. S.

#### SENSATIONAL PEARS.

At the late fruit show held at the Crystal Palace there were numerous sensational exhibits, that is to say, many fine dishes of fruit altogether "out of the common." Especially was this the case in the class for Pear Pitmaston Duchess. In this instance several grand dishes had to be passed over by the judges, not because there were any flaws in them, but simply because the fruits were not big enough. The second and third prize dishes were remarkably fine and the Pears of good form, but not nearly so heavy as those which gained the first prize. It was one of those cases where the judges must either completely pass over a dish of fruit or else give it the first prize, and they decided in favour of weight rather than beauty of form. This sensational dish of Pears was grown by Mr. J. Gibson, Draycot Gardens, Chippenham. The five fruits weighed 8 lbs. 12½ oz., and the largest turned the scales at 3½ oz., being, therefore, only a fraction short of 2 lbs. in weight. Naturally there was something of the prize-pig appearance about them, but, all the same, they were worthy of special attention as showing what can be done in this country. The tree that produced them is growing against a south-west wall, is fan-shaped, and covers a space 23 feet by 12 feet. It is about twelve years old, and has not failed to

give few or many fruits for several seasons past; in fact, Mr. Gibson has repeatedly taken prizes at Bath, Bristol and elsewhere with fruit from this tree. It will perhaps occur to many of my readers that the crop must have been light, this accounting for the extra great weight of the fruit this season. Far from it; exactly 100 fruits were left to mature, very few of which weighed less than 20 oz. It was, therefore, a decidedly heavy crop. The soil at Draycot is shallow and rests on a gravel or hot subsoil. Such conditions are not favourable to the production of extra fine fruit. On the contrary, exceptionally high culture has to be resorted to, or otherwise starved or stunted trees and small fruit would be the order of the day. Liquid manure (notably sewage water) is very frequently applied both during the resting period and in a more freely diluted state during the growing season. An annual early spring mulching of pig manure is also given, this being preferred to horse, stable or other manures for the hot Draycot soil. W. I.

**Early decay of fruit.**—"W. S." asks (p. 234) whether fruit growers in other districts are troubled with Apples and Pears decaying and dropping prematurely. The Codlins and soft fleshed varieties generally are doing so with me more or less, but Pears, although ripening much too early, are not decaying on the trees except where injured by birds or wasps. "W. S." attributes this defect to the presence of over-much moisture, but such is not the cause of decay in my fruit, as it is a long time since rain fell here, all crops now suffering much from its absence. My opinion is that when the weather sets in so tropically hot after the season has so far advanced, the ripening process is too speedy, and therefore unnatural, and that any sudden change either to wet or cold, if only for a single night, will cause the fruit to rot. Weather which will encourage a gradual maturity is what we want in autumn.—J. C.

## FLOWER GARDEN.

### THE ADVENT OF AUTUMN.

HERE and there the trees are already changing colour. The leaves of an Horse Chestnut growing on a steep slope are showing tints of vermilion, while a little further on the southern side of an Elm is golden. The Virginian Creeper is slowly crimsoning. Narrow splashes of Violet on the high bank are all that is left of the glorious mantle of imperial purple that so lately robed it—the purple of Clematis Jackmani. The garden is so bright, that at the first glance it seems heresy to say that summer is dead, but, as one walks slowly and regretfully along the borders, the brilliant scarlet of the Zinnias, the Geraniums, and Begonias, the bright gold of Coreopsis and Rudbeckia cannot blind one to the loss of the Lilies, of which but one variety, Fortune's Tiger Lily, now over 6 feet high and blooming superbly, is left, or to the fact that the "month of the Roses," that "hastes and wastes," is by now full ten weeks past, though now and again, as if to console us for the departure of the main army, a few stragglers "greet us with a smile." Safrano, latest as earliest of all, is well in its second blooming, and will continue to dower us at intervals with its delicately tinted blossoms till Christmas, should the weather remain open. Rêve d'Or, Mme. Lambert, Viscountess Folkestone, Grace Darling, pale buds of the erstwhile almost scarlet Ma Capucine there are still to gather, whilst the old Monthly Roses, Laurette Messimy the most beautiful of all, hold bravely on, and a few Coppé Austrian Briers can be

found to arrange with the chaste single white Macartney Rose with its faint ripe Pear perfume, which gives promise of blossoming for yet many a week to come. The Cape Hyacinths are things of the past, as are the Plume Poppies, the herbaceous Phloxes and Montbretias, whilst the vivid blue of *Salvia patens* has all but vanished, the less striking shades of *Agathæa celestis*, the blue Cornflower, and *Plumbago Larpentæ* but inefficiently compensating for its loss.

True, we have colour enough. *Tropæolum Fireball* has ascended a breadth of the house wall fully 10 feet high, mingling its scarlet with the white pendent clusters of *Solanum jasmoides*. Tall spikes of *Lobelia cardinalis* make high notes of colour among the browning *Pæony* leaves. The Coral Flower (*Erythrina crista galli*) lifts great spires of bloom above the Belladonna Lilies, and the dazzling hues of the Cactus Dahlias glow from their evergreen background; while from out the ruined lace of the *Gypsophila* a belated Oriental Poppy flames; but the first of the Michaelmas Daises—Good-bye Summer the cottagers call the flower—is in full bloom, and the plumes of the Pampas Grass are already bursting their sheaths.

The mid-day sun is hot, but summer is gone and the year is growing old. When one remembers it in the spring, with the opening of its first Narcissus, its carpeting of wild Hyacinths and wood Anemones, and its youthful song (voiced by the throstle) of the joy of life, one is tempted to revert to what Ruskin terms the "pathetic fallacy," and to pity it, despite the golden fruition of its dreams, the gold of the Sunflowers, of the ripe fruit, of the yellowing trees, the shaven stubble and the garnered grain—for autumn's song is sad beneath its store of gold; it has changed to a sigh (*tout casse—tout lasse—tout passe*).

In the afternoon, around the great Nut tree, from which for the last month the squirrels have industriously pilfered, a bat, dazed by the sun, flutters aimlessly, soon to seek its winter quarters under the beams of the old barn. The evening closes in apace, and the grass is drenched with dew; the air, heavy with the perfume of the sweet-scented Tobacco plant, grows chilly, and the doves roosting in the standard Magnolia are fawn-coloured balls of down.

As the night wears on one is tempted out by the clear harvest moon, and descends through a deep cutting, bordered on either side by a fringe of Ferns—Lady Fern and Hart's-tongue, Male Fern and Blechnum—towards the lakelet. On the further side a hanging wood rises aloft into the blue star-bespinkled sky, the trees a hazy mist of shimmering foliage in the moonbeams. Over the water hangs a diaphanous veil of filmy vapour; the great tree trunks in the foreground stand out, black silhouettes, the large flower-heads of the blue Hydrangeas looming dead white around their boles. The polished leaves of the Laurels below shine like molten silver; not a leaflet moves. Nature stands spellbound, entranced at her own loveliness, whilst afar, through the silence, the wood owls are calling—ever calling to the night.

S. W. F.

**Campanula isophylla alba.**—"R. D.'s" notes on this chaste and beautiful plant are interesting, and it may interest him to learn that when in Norwich a few weeks back I saw many plants of it in windows of small dwellings in the suburbs, and consider it has no rival for the purpose. In some instances it had been trained to a framework similar to Musk, but by far the best effect was produced where the pots were suspended in baskets or even separately, and the

growth and flower allowed to fall down in the natural manner. This *Campanula* is one of the many simple, yet graceful subjects which might be used with good effect in large private gardens as well as in those of the poor.—J. C.

**Layering Pinks.**—In my younger days the layering of Pinks was seldom thought of, propagation by pipings being most popular. It is true great care is needed in layering, as the stems of Pinks are very small, and unless in the hands of an expert the knife is very liable to slip too far when the incision is being made. Yet many firms annually layer large quantities and find it answers well. Only the other day I saw a splendid lot of plants, the variety being Mrs. Sinkins, which had been layered from one-year-old plants as soon as the blooming season was past. Each plant had some half-dozen good strong growths as well as abundance of fibrous roots. The early date at which Pinks flower permits of the operation being performed by the middle of June, thus giving the plants ample time to form plenty of young roots by September. Yearling plants should always be chosen for layering, as it is next to useless troubling with old growths.—J. C.

### FLOWER GARDEN NOTES.

**FUCHSIAS.**—These have done remarkably well outside this year, and together with Begonias have ranked among the best things in the flower garden, whether as big, old plants that do duty year after year, or as early spring-struck stuff grown along quickly and well hardened off before planting. The latter can be mixed with other things of similar height, whilst the larger plants may be employed as isolated specimens or for extra-sized beds. Of some few plants used in flower garden work it may be said that it is not easy to put them out of place, and this is, I think, true of Fuchsias, always provided they get a sufficient amount of room, whether large or small plants, to show them off to advantage: half their beauty is lost if other things are crowded up closely to them. Most of the free-flowering varieties are suitable for outdoor work, that is provided they are of good habit: they should not be straggling, but stocky and short-jointed, and when this habit is natural in pot culture it is always considerably strengthened out of doors. The sorts noted as flourishing in great beauty this year have been Duchess of Edinburgh, Rose of Castile, Mrs. Marshall, and Mme. Cornelissen, the last more inclined to be straggling, but of graceful habit and very free.

**BEGONIAS.**—Mr. Tallack (p. 247) is not alone in his experience of this insidious disease, and I noted it a few weeks ago under the heading of "Failures," but am sorry not to be able to offer any suggestion as to a cure or a preventive. It would seem out of doors to be due to atmospheric influences; at least an examination where the foliage is badly affected has failed to discover anything wrong either with the corm or the roots. I have had it both indoors and out since 1892, and I have nearly given up the culture of Begonias, only planting them in small quantities and in spots where they could be lifted in the event of the foliage going wrong and other plants substituted. One season, I think in 1893, the plants collapsed as suddenly and completely as the old yellow *Calceolaria* was wont to do when smitten with the disease to which it was liable. Strange to say, the few Begonias I have outside this year are quite free, there is no sign of a spot about them, the tuberous section and *Worthiana* being alike clean and healthy.

**UNCOMMON PLANTS.**—Following up the notes made a week or two ago on a few things that are not often seen in the flower garden, but which may be strongly recommended as very useful and of unique interest, I may mention one or two more equally good. The deep shade of blue of *Salvia patens* is somewhat akin to the colour met with in the flowers of the old trailer *Maurandia Barclayana*, and is almost unique in summer flowers. The plants flower with great profu-

sion and associate well with many things. They look, for instance, remarkably well with a good strain of Pentstemons, or thinly mixed with silvery Centaureas or Gnaphalium lanatum. Eucalyptus citriodora is not quite so silvery as the better-known *E. globulus*, but is a plant of graceful habit, throwing out the drooping side shoots very effectively, and, as the name implies, with very nicely scented foliage. It makes a pretty bed with Heliotropes or the taller-growing Ageratum. Raised from seed with *E. globulus* it will grow as quickly and with equal freedom. *Nicotiana colossea* is apt to get ragged and torn with rough winds and heavy rains, but in a season like the present it is one of the best fine-foliaged plants in cultivation for outdoor work, from the fact that, besides furnishing leaves of exceptional size, it is anybody's plant. It can be grown easily and quickly from seed. Seed was sown this year the last week in February and plenty of plants are 5 feet high with individual leaves 30 inches long by 16 inches in breadth. It is valuable for a large bed or as a background to flowering plants of dwarfier habit. I have not tried it as a pot plant, but should imagine, with plenty of room and good feeding, it would answer remarkably well and make a very effective plant for large conservatories, corridors, &c. A note should be made of the Coral tree (*Erythrina crista galli*) for grouping in some sheltered spot. A stock can be secured from seed, but this should be sown early with the Begonias and Centaurea. The plants once acquired can be lifted annually and stored away with Fuchsias and similar things.

**ZINNIAS.**—A variety known as *robusta grandiflora* has done remarkably well this year, and, given plenty of room, the plants develop into fine bushes 3 feet in height and 2 feet in diameter. Beds or groups of Zinnias have been used in the flower garden for many years, but the variety above-named is comparatively new. Of recent date, too, is the introduction of good types of Zinnias in mixed beds, and if the planting is well done the effect is very pleasing. It is gratifying to note the great improvement effected in mixed beds in the last year or two; indiscriminate huddling together of odds and ends is now seldom seen, the planting is carefully done, and, with a due regard to the judicious blending of colours, such beds rank amongst the best things in the flower garden.

**TUFTED PANSIES.**—Among the varieties referred to in one or two notes that have recently appeared is *Duchess of Fife*. I am anxious to know if it does well with the writers, as after trying it in one or two parts of the garden and under different conditions I am obliged to pronounce it a failure; the only variety in about a score that gets badly diseased and about half way through the season has to be taken up. The best substitute is *White Duchess*, a variety of good constitution and very free. Although the Tufted Pansies have furnished an abundance of flower right away through the season, I have had a similar experience to that chronicled in 1893, viz., that all the varieties other than selfs soon lost their true form, and after a long spell of drought, it was difficult to name the different sorts; indeed, if one took blooms from, say, *Duchess of Fife*, *Blue Cloud*, *Lilias*, *Annie King*, and others of this type and mixed them up, it was not only impossible to separate them, but in the majority of cases hard to distinguish them from an old white variety with a dark eye and slight petal markings. In formal bedding arrangements where the retention of colour is necessary, it is always advisable, having acquired good selfs in the different shades, to hold fast to them, reserving those of uncertain or mixed colours for places where a profusion of flower is all that one requires, and not that a special colour should be retained right through the season. I notice a correspondent in referring to *Annie King* says that it is a sport from *Ardwell Gem*. It is another proof of the eccentricity of this particular class of Tufted Pansies that when the changes of colour come, as the result of hot weather, this sort with me never approaches a yellow or even a primrose shade, but rather inclines towards the whites.

**STARWORTS.**—I should like to direct attention to the extremely useful properties of two or three varieties of Starworts now in flower where a quantity of cut bloom is required. These are *vineous var. Cassiope*, *ericoides*, and *Tradescanti*. Not only are the flowers produced in great profusion, but in the case of the first and last-named the foliage is very small and the general habit of the plant light and graceful. I shall mark the clumps of these varieties, with the view to splitting them up at the proper time. It may be well to note that it is not advisable to split up all the stock the same season. Old-established clumps naturally flower more profusely than small pieces, and a few should therefore be preserved. A change in the weather (October 2) and slight indications of frost have necessitated a busy afternoon in housing plants in pots, in lifting tender things from the ground that are yet out, and in covering up with mats or stretches of tiffany anything that, being tender, cannot be as yet taken inside. Colder weather will be welcome from one standpoint, that of checking the luxuriant growth of Grass. It is seldom that so frequent mowing is necessary at this season of the year as has been the case in 1895. This and the accompanying edging of beds and verges are always a nuisance when one is specially busy with the ingathering of the fruit and root crops. E. BURRELL.

Claremont.

#### LILIUM SPECIOSUM AND ITS VARIETIES.

IF "H. P." writing in THE GARDEN, p. 247, on this subject, will turn to my papers in THE GARDEN, vol. xl., p. 442, and vol. xlii., p. 471 (1891-92), he will find there the principal Japanese varieties in the speciosum group for the first time fully described. Pre-eminent he will find there the very beautiful and richly coloured form with white tips and edges now generally known as *Melpomene*. The form which he mentions as *rubrum superbum* is, I take it, the one which I there described as *macranthum*; it has very large flowers, beautifully coloured, borne on long slender pedicels, very symmetrical and broad-petalled. The variety which he mentions as "the latest of all" is described by me as *eruentum* (vol. xl., p. 472, and vol. xlii., p. 468), a very dark-coloured variety with short, erect, stiff foliage. Besides these there are two other distinct and good varieties—*compactum*, somewhat later in flowering than *macranthum*, with buds and flowers highly coloured externally; it has foliage dark green and erect, and is very free-flowering; and *nanum*, rather a late form, with drooping foliage and broad-petalled flowers of a soft rose shade.

In the roseum group there are two very fine varieties—*formosum*, early flowering, with a symmetrical, broad-petalled flower of a soft rose shade, and *roseum superbum*, mentioned by "H. P.," which is by far the finest of the roseum section. This form has a large symmetrical flower of great substance, beautifully rose-tinted; the foliage on a green stem is shaped much like that of *Melpomene*. Imported bulbs of this variety generally flower late, but if grown on a year or two come much earlier into bloom.

I have this summer had the pleasure of flowering for the first time *Lilium Lowi* and *L. nepalense*. Both these I think might be grown successfully in the warmer districts of Great Britain in the open air, but require to be lifted in the winter months and protected from cold rains and sharp frosts. *L. Lowi* is early in starting, grows rapidly, shows its bud almost from the first, and flowered here freely in July and August. Some bulbs threw as many as four graceful flowers on a stem. *L. nepalense* bloomed in September, and is still flowering;

it starts a little later than *L. Lowi*, grows very rapidly, and is distinguished at once by its smooth, dark stem; whereas that of *L. Lowi* is light-coloured and pubescent. *L. nepalense* grows tall and will throw numerous flowers. I have heard of one plant 9 feet high with several blooms. Both these *Liliums* will, I think, prove great favourites. *L. Lowi*, from its purity of colour (white and rose ribbed outside, with numerous purple spots), is quite a lady's flower, while *L. nepalense* with its rich colour boldly arrests the admiration of the spectator.

ALEXANDER WALLACE, M.D.

3, St. John's Terrace, Colchester.

#### AUTUMN SNOWDROPS, CROCUSES AND MEADOW SAFFRONS.

IT is interesting to observe from Herr Max Leichtlin's notes in THE GARDEN of September 28 (p. 252) that he thinks *Galanthus Olgae* *Reginæ* so much earlier than *G. nivalis* *octobrensis*. It is not, however, above the soil here to-day (October 2) and appears to be little in advance of *octobrensis*. I have examined both carefully, and find that there is at present little difference in the growth they have made. Both kinds are established bulbs and stood last winter without protection—a severe test. Brilliant weather for some weeks has been very favourable to the *Croci* and *Colchicums*, both lasting in flower longer than usual. *Crocus pulchellus* has been much admired, its delicate pearl-blue flowers prettily striped being exceedingly pleasing. *C. iridiflorus* has also been flowering well and is worthy of being more widely grown than it is. A clump of imported corms of *C. pulchellus* collected on the Bithynian Olympus a few years ago show considerable variation. This *Crocus* seeds freely here and seedlings are being raised annually. A collection of these autumn-flowering *Croci* is well worth the little trouble involved. I grow a good many species and derive much pleasure from their beauty. The *Colchicums* are less refined, but are also valuable, and considerable variety can be had. *C. Sibthorpi* is one of the finest of those with distinctly chequered flowers. It is large and of good form and is not so easily destroyed by strong winds and heavy rains. It has also the advantage of flowering considerably earlier than *C. Parkinsoni*, which does not appear to be happy in our northern climate and flowers both late and imperfectly. The double Meadow Saffrons are much admired by many of my garden visitors. The best of these is the double white variety of *C. autumnale*, but the others are also appreciated. The Meadow Saffron is well suited for growing in grass, and when planted in the border should be carpeted with some low-growing plant which would support the flowers, the greenery by which they are thus carpeted adding much to the effect. A clump of the double purple *C. autumnale* growing through the foliage of Crown Anemones, which always make autumn growth here, has been much admired.

Since writing the foregoing I observe in other parts of the garden two Snowdrops which were nearly an inch above the surface on October 4. These were obtained under the names of *Galanthus coreyrensis* and *G. montanus*. They are small and slender varieties, but hardy here. The original *G. coreyrensis* as first introduced flowered in December, but one cannot be very certain of the names of these autumn Snowdrops. S. ARNOTT.

Carsethorn, by Dumfries, N.B.

**CALOCHORTUS VENUSTUS AND ITS VARIETIES.**

THESE beautiful, but long-neglected bulbous plants have been brought prominently forward of late, and their frequent appearance at the R.H.S. meetings, together with the plates of several varieties that have been published in THE GARDEN, will doubtless have aroused a desire among others to try their hand at growing them. Messrs. R. Wallace and Co. have proved in their nursery at Colchester—a district not more favoured than southern gardens—that Calochorti can be grown to perfection, and the charming groups of this flower that they have shown at the Drill Hall during the past two seasons will doubtless be fresh in the minds of many who saw them. They have also made several very fine additions to the Calochortus family, which now grows in number and importance every year. The variety here illustrated is one of the latest additions. It belongs to the *C. venustus* section, which is the finest of the family, and comprises some of the hardiest, freest blooming and most easily grown kinds. *C. v. pictus* was shown at the Drill Hall on June 24 this year, when it received an award of merit. The flowers are not quite so large as these of the ordinary *C. venustus*, but they are neatly shaped and of a purer white than those of any other variety of this section. The eye-like blotch on each petal is reddish brown, and there is a profusion of rosy spots at the base of the petals. It is a lovely form, sturdy in growth, and free blooming. The beginner in Calochortus culture could not do better than take this group, and, in addition to the variety just described, which though new is cheap, he should also grow *C. v. oculatus*, which is an exceedingly free-flowering kind with rose-purple buds and white flowers, of which the eye is black margined with yellow. *C. v. citrinus* is a gem, of a pale lemon-yellow beautifully blotched and pencilled. *C. v. purpurascens* is deep purple externally and useful for its lateness. *C. v. roseus* is one of the earliest in this group, and is easily dis-

tinguished by its triangular rosy blotch. *C. v. Vesta* is one of the most vigorous, and has an extra large flower which is creamy white, streaked and spotted with reddish brown and yellow at the base, whilst *C. v. Vesta albus* is its counterpart in size, vigour, and freedom, but its pure white flowers have no spot or blotch, only a slight yellow stain at the base.

*Calochortus venustus pictus.* Engraved for THE GARDEN from a drawing by Miss E. Carter.

Those who begin with and flower these to perfection will certainly be fascinated with their quaint beauty. Success is not difficult to attain, and the details which lead up to it we need not now enumerate, as they will be found on p. 20 of THE GARDEN for July 13 of this year.

**Autumn-sown tuberous Begonias.**—Many gardeners experience considerable difficulty in

successfully raising these Begonias from seed in the early part of the year. To any such having a little heat at command during the winter I would suggest raising these things in the late summer or early autumn months. Some of the drawbacks to raising them in January and February are that by the time they are large enough to prick off a great deal of other work is pressing. Another thing, and also an important matter, is that the January-sown plants are usually too small in June to make any show till they have been some time planted. And again, in the waning of the year the duller days are more congenial to the safety of the young plants that in early spring frequently suffer from a sudden burst of hot sunshine or dryness. I may be told that the young plants will more readily damp off in the winter, but I do not believe this if they are kept away from drip and water given very sparingly at all times. A neighbouring gardener who plants freely and exhibits occasionally prefers autumn sowing, or rather, in his case, it is late summer sowing, as by the middle of September the young plants were ready for pricking off. In this way he obtains much larger plants for bedding, while the earliest are employed for pots. With a good assortment of kinds he selects and saves his own seed. When the pods are ripe he fills an ordinary pan with soil, and, taking the pod with finger and thumb, scatters the seed on the surface soil which has been previously well saturated with water. The pans are then placed in the dark, and if water is needed prior to the germination of the seeds, the pan is held in the water tank, but not allowing the water to reach the surface. These new seeds germinate very quickly and abundantly, several hundred seedlings appearing in a pan 8 inches across. Nor was it an isolated case, for the several pans I saw were just the same, simply one mass of the tiny leaves of the Begonias. In all there were thousands of plants in less than three weeks from the sowing.—E. J.

**THE POISON OF PRIMULA OBCONICA AND P. JAPONICA.**

ON page 218 I observe an inquiry about this. Whether the pollen of *P. obconica* produces eczema of any kind I do not know, but handling the leaves in pulling the plants to pieces certainly produces an irritating eruption on the hands of some people, of whom my gardener is one. I have more than once tried passing the front of my wrist over the leaves without effect, but two or three weeks ago I had a different experience with the leaves of *Primula japonica*. Some unflowered seedlings had grown closely together on a soil heap, and had very luxuriant leaves a foot long. I was half-an-hour pulling them apart and packing them to send away. That night, so violent an irritation came on the palms of my hands and my wrists as to keep me awake nearly all night. The appearance produced was something like the rash of scarlatina. The irritation lasted for three or four days, and in nine or ten days my hands and the sides of my fingers peeled. I have not the slightest doubt that handling the large green leaves of the Primroses was the cause. I have been before told on good authority that this skin irritation was produced by other Primroses besides *P. obconica*.—C. WOLLEY-DOD, *Edge Hall, Malpas.*

— A few years ago I had a plant of *Primula obconica* in which I took great interest. Finding the persistent way in which it flowered for at least nine months of the year and its value for decoration, I determined to grow it in quantity, and the following year I raised some six to eight dozen seedlings, which I attended to myself from the sowing to the final potting. Now during the month of March the period of transferring the seedlings into small pots, I had my first attack of a very irritable form of skin disease on my hands and face, which continued very frequently for over a year. During that time I spent some £20 in doctors' bills, &c., all to no purpose, as every

attack became more severe, until I read in THE GARDEN columns a statement that the Primula was the cause of others suffering in the same way as I had done. I at once discontinued to touch the plant, and from that time I have been quite free from what the doctors called a very severe form of eczema. My first attack of the disease took place when removing the seedlings (that is, before any flower-spike was seen) into small pots: also, when I later on pinched off the flower-spikes before the flowers were open to strengthen the plant. I am quite certain it is the foliage and not the pollen that causes the irritation of the skin. I believe it is the hairy growth under the leaves and on the flower-spike that is the cause of all the mischief.—W. HUNTER, *Baron Hill, Beaumaris.*

— In the interest of all lovers of gardening, especially those amateurs who delight in growing an assortment of free-flowering plants for the window or sitting room, I gladly reply to Mr. Burrell (p. 218) concerning the above plant. In doing so I have no hesitation in saying at once that this decorative free-flowering plant is positively dangerous to many people. This fact cannot be too widely circulated, because, by reason of its freedom of flowering and also the never-failing succession of its spikes of blossom, the plant is now being extensively grown in all provincial towns. You can scarcely name a country market, large or small, where you will not find pot plants of it, a fact alone which is responsible for its appearance in so many cottage windows. In this way it is highly probable that scores may be suffering from its effects who never dream of the source from which the danger springs. The strange part of the business is that some people can handle it at all times with impunity, while others hardly dare to venture within touch of it. This fact has caused many to discredit its dangerous properties. But as one who has had between six and seven years of suffering directly traceable to this plant, I speak without hesitation, and if I had to choose between two plants, I would much rather handle a bunch of stinging nettles than touch the Primula above-named. It took me years to find out the cause of my suffering, and after spending much money with the doctors, all of whom had a different name for the disease, and gave me all sort of remedies. In my own case the itching, scarcely endurable at any time, always became intolerable at night, when the body was more uniformly heated. I adopted homely remedies and suggestions by the score, all to no purpose. Eventually, unable to longer endure it, I went to one of the London hospitals for skin diseases, and after undergoing an examination extending to some forty minutes, the disease still remained a puzzle to the seven doctors who had gathered around me, and who put to me questions without end. They could not reconcile the exceeding redness of the skin and the numerous watery pustules that were present on my hands, lips and other parts of my body with any known skin disease. In the end they prescribed an ointment to allay irritation, ordered me quinine in large doses, &c. The ointment certainly relieved the irritation, but was of course no cure. I think it is now nearly six years since I sent notes to the various horticultural journals re-pecting the poisoning caused by this plant. At the same time I mentioned I was in possession of an ointment that would allay the irritation for the time. The numerous applications I have received for the ointment form the best proof of the numbers who were then suffering from this plant. In my case the disease was infectious, but only to myself—that is to say, any part of my body touched by the affected part also became affected. And in this way my eyes, nose and lips were all affected because touched by the hands. It will interest Mr. Burrell to know that a variety of experiments, purposely conducted, proved conclusively that it is the numerous glands on the leaves and stems that contain the (to me) poisonous element; for after I had discovered the source of the trouble, as I thought I was slow to proclaim it, because my little daughter (then

three years old) and myself were the only persons affected by the plant out of a dozen or fourteen—hence the experiment, which left no doubt behind. After this I studiously avoided the plant and put it out of reach of the little one. It is now upwards of five years since I touched the plant, and I have been quite free from the disease: but had it been caused by the pollen, I could never have rid myself of the disease, because the wind may have carried the pollen in all directions, and some, at least, from the quantities of plants grown would have certainly found a resting-place on me. But it is not so: it must be contact with the glands, and the only cure to those who suffer is to let the plant severely alone. I believe a large number of American horticulturists suffer from this plant. It would be interesting to know if a microscopic examination of the glands of the leaves would throw any light on the subject. It is well that Mr. Burrell has directed attention to this subject, so that those who grow it may know how to act should any extreme irritation arise to those in touch with it. In my own immediate district I only know one other case, and this a foreman in a private garden, who, I believe, suffers from contact with the Chinese Primulas also, though not to the same extent.—E. H. JENKINS, *Hampton Hill, Middlesex.*

#### THE NATURAL DISTRIBUTION OF PLANTS.

I NOTED the other day in our pleasure-grounds an instance of self-distribution and propagation that in the more remote parts of the garden seemed akin to the natural increase of herbaceous plants already recorded. A regular colony of young Alders is coming up thickly on the margin of the lake, and it seemed at first difficult to imagine how they came here, no old tree being anywhere near. As a matter of fact, the seed had come from the other side, some 300 yards away. There is no sign of young growth in the neighbourhood of the old tree, and the inference is that a strong wind caught the seed and carried it clean across the water, depositing it at last on the margin on a bed of moist vegetable matter, where it quickly germinated. On sloping land the heavy storms of summer are always answerable for the distribution of plants. I shall look forward with considerable interest to another visit to a part of the Surrey hills between Dorking and Guildford, where early in the season was to be found on a small area a splendid variety of hardy plants. The spot in question is on the south slope of the hill, and is a portion of the down land that was apparently broken up with the view to continue it as arable land, but afterwards neglected. The slope is a sharp one, and I strongly suspect one will find another season that the seeds of many plants that had their origin on this piece of neglected land will have been carried down the entire length of the slope and founded a new colony at its base. On a smaller scale this carrying down of seed has been in evidence on one or two of our fruit tree alleys, where I have found small batches of Campanulas and Antirrhinums. They flourish on the broken coping in many places on our old walls, the seed drops, a heavy rain carries it along the alley, and it springs into life perhaps 30 yards or 40 yards from where it fell from the wall. Is the after distribution of Mistletoe on trees when a single piece is once established due solely to natural causes or the work of birds, and if the birds have nothing to do with it, can the appearance of the parasite on many branches be always attributed to the dropping of seed? Close observation of a Sugar Maple that is becoming thickly studded with the Mistletoe shows in many cases a solitary leaf with stem making its appearance, but there is not the slightest indication of any fissure in the bark in which the seed could have dropped, and besides this many twigs are showing under the branches where the deposit of seed in any way is practically impossible. It would almost indicate that the distribution of Mistletoe on a tree is almost identical with the spread of a plant

of rambling tendencies in the ground, Couch Grass for example. The improvement in constitution of natural flowers by accidental distribution is in a country ramble quite as apparent as the fact of the distribution. The yellow Toad-flax, for instance, makes its home on many a slope of the hills, and flourishes despite the shallow soil, but when it gets part of the way down the slope, where the surface soil, washed down by rains and lying perhaps a foot in depth through being arrested in its downward progress by some stones or a projecting spur of ground, is, the vigour of the plant and the size of the flowers are greatly improved and the flowering season is considerably lengthened. Take, again, the case of a quantity of the wild Violet growing, perhaps, on a bank in light, rather poor soil. A small piece is by some means transferred to a more shady bank where the soil is strong and somewhat heavy; the foliage is much stronger and healthier, the flowers are larger and decidedly of firmer texture; indeed, the whole character of the plant is changed. I take it that whilst the evidence of the reproduction and distribution of plants is interesting, the study of the improvement effected by altered, but at the same time natural, conditions and brought about by what may be called a natural manner is instructive as well as interesting.

Claremont.

E. BURRELL.

**Erodium supracinerum** is a diminutive rock plant with whitish blossoms distinctly veined with red. In general appearance the flowers of *E. supracinerum* have some resemblance to those of *E. macradenium hybridum*, but in point of foliage the plant is quite distinct from that kind. Instead of the delicate Fern-like foliage of *E. macradenium*, the leaves of the above plant are silvery white and rest closely upon the soil. For so small a plant it is free flowering, though not comparable with the other species in this respect. While interesting and distinct, this Spanish dainty certainly does not appear any too vigorous in constitution judging by a small plant of it in the Kew rock garden.—E. J.

**Kniphofia modesta**.—This is a very distinct and dwarf species with small spikes of closely-set whitish blossoms. The plant is from Natal, and, judging by the position accorded it at Kew, as may also be conceived by its native habitat, the species will not endure frost. One feels the appropriateness of its specific name when we remember the giants of the race, *K. grandis*, *nobilis*, and others, that tower far above one's head with their pyramids of scarlet and gold. The species above named may find a congenial home in the winter garden or cool conservatory. In such places its freedom of flowering and dwarf stature may be welcome, especially if associated with other things in the rock garden portion.—E. J.

#### SHORT NOTES.—FLOWER.

**Polygonum vaccirifolium**.—What a charming vase plant for autumn decoration this is! Grown in a pot and allowed to extend itself as it likes, it is admirable for replacing other things that have done flowering. Its long wiry stems hanging round the sides are covered with the pretty pink spikes, which continuing until cut by frost are very effective.—J. M., *Charmonth, Dorset.*

**Campanula Hendersoni**.—This is a hybrid form of *C. carpathica*, the flowers mauve or pale blue, produced in rich pyramidal racemes, very handsome, and an excellent border variety. It can be increased by means of cuttings, root division, or seeds. Seedlings show some variation, as might be expected. I recently saw this fine plant in very effective form in an open, sunny position on a border, and doing well in ordinary garden soil.—R. D.

**Quilled Asters for cutting**.—These have several recommendations for this purpose—their symmetrical shape, never large to ungainliness in a good strain, varied in colour, with long, stiff stems, lending themselves for association with other flowers. These are a few of the qualities which make this type so acceptable for decoration. They have not the stiffness of habit belonging to some of the types, and they are a conspicuous feature in the border.—R. D.

## STOVE AND GREENHOUSE.

## RHODODENDRON LADY ALICE FITZWILLIAM.

THIS is the result of a cross between *R. Edgeworthi* and *R. Gibsoni*, and is of a denser and

colder habit than *R. Edgeworthi*. The flowers, pure white, sometimes marked on the outside of the tube with a faint streak of rosy pink, are borne in trusses of from three to five, each bloom measuring 4 inches across and in some cases  $4\frac{1}{2}$  inches. It is valuable in the conservatory as much for the delightful fragrance of the flowers as anything else, a few being sufficient to scent a large house. It does well in

cold greenhouses and unheated frames, and may be described as half-hardy. By forcing it may be had in bloom at Christmas, but it is better to let it flower naturally in the spring. It sets its flower-buds very freely.

**Carnations diseased.**—I enclose you a few leaves of my Malmaison Carnation affected with

its spores all over the leaf in the form of minute brown dust. The leaves you sent are covered with these spores, which naturally spread to and affect other healthy leaves. This fungus vegetates between the membranes of the leaf—is, in fact, an internal disease that no outward application of remedies can affect. The only efficient way of dealing with the trouble is to pick off and burn every leaf that is seen to be affected and before the spores are distributed. Plants very badly attacked had better be burnt. All healthy growth should be persistently sponged with a weak solution of Gishurst compound. By patience and perseverance in these details only can you hope to bring the plants back into a healthy state of growth.—Ed.

**Lilium nepalense.**—This Lily seems during the present season to be more grown than heretofore, as it may be seen flowering in many places where treated as a greenhouse plant. It is certainly a very distinct Lily, and though the flowers are beautiful, it is not at all likely that it will become a popular Lily, as it often runs up tall and weak, and is after the first season not very amenable to cultivation. The additional numbers seen this year may, I think, be attributed to the fact that a few large importations came to this country in the spring, and one at least of considerably over 1000 bulbs was disposed of at the London auction rooms as mixed species from the Shan States of Upper Burmah. These seem, however, to be nearly all *L. nepalense*, at least as far as I have seen them in flower. There is a certain amount of variation to be found in the flowers of this Lily, as in some the chocolate at the basal half of the petals extends much further down than others, while the greenish yellow of the rest of the flower also varies in hue. *L. nepalense* must be regarded as one of the expensive Lilies, and as it is necessary to keep up the stock by continual importations, it is not likely to become particularly cheap, as in the case of those that are readily cultivated in this country or on the Continent.—H. P.

**Bearded and spotted Begonias.**

—By same post I send you a box of cut flowers of new Begonias. The bearded Begonias have been obtained quite recently, and are to be offered to the trade next spring. Only five or six colours are bearded, but in a year or two all shades will be obtained. It is a start only, and probably in a short time we shall see other surprising novelties in this group. The spotted Begonia is a new strain, very promising. The aim is to obtain flowers spotted like those of a Gloxinia. It will not be sent out for a year or two. There is another wonderful novelty with large regular flowers, the petals of which are undulated and fimbriated. The flowers, of great substance and of the brightest colours, assume the shape of a gigantic *Primula sinensis fimbriata*.—D. GUHENEUF, Paris.

\* \* A very interesting series of flowers of good colours. About the centre of each petal is a curious Lichen-like growth of the same colour, or slightly different, giving the flower a very singular and sometimes beautiful effect. The spotted kinds, without these appendages, have large spots of white, clearly set in the body colour, sometimes irregular in size and running together.—Ed.

**Winter-flowering Carnations.**—In reply to Mr. Godfrey's criticism of my letter of a fortnight

*Rhododendron Lady Alice Fitzwilliam.* From a photograph sent by Mr. E. Metcalf, Mill House, Hulfar.

more bushy habit than *R. Edgeworthi*. The flowers, pure white, sometimes marked on the outside of the tube with a faint streak of rosy pink, are borne in trusses of from three to five, each bloom measuring 4 inches across and in some cases  $4\frac{1}{2}$  inches. It is valuable in the conservatory as much for the delightful fragrance of the flowers as anything else, a few being sufficient to scent a large house. It does well in

a fungus. I have tried everything I can think of, but cannot succeed in growing them. Can you give me any advice through THE GARDEN?—D. FAIRWEATHER.

\* \* Your Carnations are badly attacked with a fungus named *Helminthosporium echinulatum*, which differs materially from the more familiar Carnation spot (*Uredo dianthi*). It appears first as a small swelling, which bursts and distributes

ago in your issue of last week, I did not say, nor did I intend to infer, that the varieties I exhibited in November last at the Plymouth Chrysanthemum show were winter-flowering Carnations. Exactly the reverse. My letter was intended to point out to the amateur a way by which the period between the end of the flowering season of the border varieties and the commencement of those that are strictly winter-flowering kinds might be bridged over, and hence the constant succession of bloom be kept up. Moreover, my remarks were not intended for the professional florist or "up-to-date" grower (as Mr. Godfrey expresses it), but for the benefit of such persons as were not aware of the fact that a sort of second crop of blooms could be obtained in this way. If the American varieties are what Mr. Godfrey says they are, so much the worse for the Americans, for it is well known that Carnations are favourite flowers in America, and that they are grown in enormous quantities exclusively for winter blooming, and it was to see myself (and also allow my friends to do so) what they admired so much over there that I imported those to which I have referred. The nine varieties, the names of which I gave in my last letter, are included in the dozen which the chairman of the Society of American Florists gave as the best Carnations in America at the present time. I do not wish to go beyond that, as I have not as yet seen them bloom. I have seen photographs of them, and they certainly appeared to be very fine. The American plants, blooming as they have been specially prepared to do in the winter, could not come into competition with our English flowering varieties in any way, as there are no exhibitions at that time of year. The intention is simply that they shall add an additional charm to the conservatory and to the collection of the amateur in a class of Carnations of which we have at present far too few that are really good.—H. W. WEGUELIN, *Shaldon, Teignmouth, Devon.*

## FRUIT AND VEGETABLE CROPS.

### IRELAND.

**Vice-Regal Gardens, Dublin.**—Fruit crops in our neighbourhood are fairly good, except Apples and Pears, which are light, the result of a sharp frost when in flower. All sorts of small fruit are heavy and good. Peaches and Apricots have set better than they have done for some years past. Plums on walls have also done better than usual. I cannot say that I have been successful in growing Plums as standard trees in our soil, which is heavy loam with clay bottom; they never ripened their crop in a satisfactory way, and after various schemes of root-pruning, transplanting, &c., were tried I cleared them off and planted Pears instead. Perhaps my want of success may be a hint to others in their choice of ground. Unfortunately, gardeners, as a rule, have very little choice in this respect. I am convinced, however, that with a good friable loam, a porous bottom, and moderate shelter, Plums as standards can be grown with every prospect of a paying crop. My experience leads me to prefer good old standard varieties such as Coe's Golden Drop, Denniston's Superb, Green Gage, Guthrie's Late, Jefferson, and Kirke's Seedling for flavour, and the following half dozen for cooking: Magnum Bonum, Pond's seedling, Prince of Wales, Reine Claude de Bavay, Denyer's Victoria, and Washington. The severe winter through which we have passed seems to have done no harm to fruit trees, but vegetables and many varieties of evergreens reputed to be hardy suffered badly, not so much from the frost as from the continuous north-east wind which prevailed throughout the winter and spring.

The long drought in May and June has left its mark on the supply of summer vegetables, especially Cauliflowers, which buttoned off wholesale. Some of my neighbours who grow them extensively had to plough them up. I have seldom

experienced such difficulty in getting seeds to germinate, a considerable proportion remaining dormant in the ground until the July rains came, which have thrown the ordinary routine of cropping considerably out of gear. Green crops of all kinds are now doing well. Potatoes promise to be a heavy crop, the tubers large, but rather soft. At present a clear, dry autumn is greatly needed for maturing crops of all kinds.—G. SMITH.

### SUPPLEMENTARY.

**The Gardens, Woolley Park.**—I have had an abundance of fruit of every kind. Raspberries fine. Apples a very heavy crop, and also Pears. I have also Plums in abundance, the trees weighed down with fruit. This is not always the case, as we very often suffer from spring frosts. I had a similar crop about fifteen years ago. As a rule we only get thin crops, as the soil is rather too light for Plums. I consider the Plum worthy of more extensive cultivation. The kinds that do the best here for orchards are Purple Gage, Orleans, Washington, Magnum Bonum, Green Gage, Pond's Seedling, and Diamond; for walls, Early Favourite, Coe's Golden Drop, Kirke's, Early Rivers, and Victoria. I find Plums do the best where the soil is rather of a clayey nature.—GEO. HUDSON.

**Claydon Park, Winslow, Bucks.**—The fruit crops in these gardens and neighbourhood are very good. Apples are a good average crop, fruit clean and promising well. Pears are a fair crop, the trees looking very healthy, especially where they were well watered during the dry season. Cherries and Plums are also good. Strawberries heavy crops and of good flavour. Currants, Gooseberries, and Raspberries are good crops.—J. MILSON.

**The Gardens, Tring Park, Tring.**—The fruit crops here, taking them all round, are the most satisfactory we have had for some years. Apples are an average crop, trees very healthy and fruit swelling rapidly. Pears a full average and very good. The same remark applies to Plums and Cherries. Bush fruits have been excellent and very clean. Strawberries were a good crop. Walnuts are thin, but Cobs and Filberts are exceptionally heavy.

The earliest Potatoes were under sized, quality good, and crop a full average one. Late kinds in fields and allotment gardens have improved very much since the rain, and promise, if not attacked by disease, to give good returns.—ED. HILL.

**Osterley Park, Isleworth.**—The fruit crops in this immediate neighbourhood are exceptionally good, Apples and Pears being most abundant. Strawberries have been a heavy crop and good in quality, President and Sir Joseph Paxton being the best. Competitor bears well, the fruit of large size, but the flavour is decidedly bad. Raspberries have greatly improved since the rain. During July we registered 4.52 inches for the month. Plums good, such varieties as Prince of Wales and Victoria being heavily laden. Peaches without protection on walls are excellent, Grosse Mignonne, Dymond, and Royal George being the best. Hale's Early was gathered on July 28. Gooseberries and Currants an average crop. Walnuts are plentiful, Cobs below the average.

The severe winter we experienced proved disastrous to most of the green crops, but Cabbages pulled through remarkably well and came in early considering the season. Cauliflowers wintered in frames and planted out proved to be the best we have had so far this season. Peas suffered a great deal owing to the drought during May and June, as during these two months we only registered 0.88 parts of an inch, Sutton's May Queen (early) and Autocrat (late) being the best. The latter I consider one of the best Peas in cultivation, having grown it several years. It has a fine strong constitution, crops freely, and is of excellent flavour. Runner Beans are better than for several seasons past. Onions, autumn sown, have produced some fine bulbs, but spring sown are much smaller than usual. Green crops,

such as Brussels Sprouts, Kale, Broccoli, look promising and are growing freely. Potatoes of the early varieties have not cropped so freely as usual owing to the drought, but the quality has been good. Late sorts are growing fast and promise a good crop.—JAS. HAWKES.

**Powis Castle, Welshpool.**—Fruit trees are looking remarkably well after the severe winter, and showing abundance of fruit blossom. A favourable time experienced during the expansion of blossoms resulted in immense crops of fruit of all kinds, excepting Pears and Apricots, the latter almost a total failure. Pears are thin and rather small. Apples good and a very heavy crop, all varieties bearing well and requiring a lot of thinning to ensure fine fruit. The dry spring no doubt caused the small size of Pears, but Apples do not seem to have suffered from the drought so much. Plums are an enormous crop, the branches requiring to be propped up to save them from breaking down. These, like Apples of all common varieties, will scarcely pay for the picking. Peaches and Nectarines here are nearly all grown outside and there is a remarkable crop this season. Tender old varieties like Royal George are this year a picture, and I never remember seeing them look better, trees neither blistering nor troubled in the least by fly. Cherries a heavy crop and good. All small fruits abundant and of good size, trees free of blight. Strawberry beds dressed with fine bone meal and given a good soaking of water, so that the drought in the early season did not affect them, resulted in very heavy crops, late varieties like Latest of All finishing up well. Nuts are abundant and good. Plums of almost all varieties do well here as standards.

A good season for vegetables of all kinds where attention was given through the drought. They, also Apples and all fruits in the neighbourhood of Montgomery, were riddled with pieces of ice in the thunderstorm at the end of the dry weather.—J. LAMBERT.

**Wynyard Park, Stockton-on-Tees.**—Taken all round, the fruit crops in this neighbourhood are very good. Apples are a capital crop and the majority of the fruits very fine and clean; our best are Ecklinville, Tower of Glamis (these two particularly fine), Stirling Castle, Lane's Prince Albert, Scarlet Pearmain, Keswick Codlin, Beauty of Kent, Cockle Pippin, Blenheim Orange, Bramley's Seedling, Cambusnetban, Stone's Seedling, Worcester Pearmain and Red Astrachan. Pears are quite an average crop and most of the fruits finer than usual. The best are Clapp's Favourite, a Pear that does exceedingly well in the north and is this year exceptionally fine in many parts of the county; Marie Louise, Fondante de Cuerne, Vineuse, Doyenné du Comice, another good Pear for the north; Beurré Diel, Flemish Beauty and Napoleon. Plums are enormous crops both on walls and standard trees. The best on walls are Kirke's, Jefferson, Washington and the several sorts of Green Gages. I may say here that all the better kinds of Plums require to be grown on walls in this part to succeed. Victorias on standards are simply magnificent crops, and Rivers' Early has been good. There are also fine crops of Magnum Bonum, though I much doubt this kind ripening up sufficiently for use; still, should we experience another fortnight of such weather as at present it will do wonders towards ripening all late fruits. Apricots have been an entire failure, the late frosts killing all the bloom. Merello Cherries have carried splendid crops of very fine fruit much above the average, but the sweet kinds do very little good outside in this part. All bush fruits have carried heavy crops and the fruit very fine. Raspberries were not so good as usual; the canes suffered severely from the very sharp frosts of February. Strawberries have been very good, certainly better than usual; as a rule, Strawberries do not do particularly well outside here, and we have to rely on a few sorts only for our crops. Those I have found do best here are Vicomtesse H. de Thury, La Grosse Suerée, President, and from present experience I think very highly of

Royal Sovereign, Gunton Park and Lord Suffield, and think they will do well in this locality—at any rate, my experience of these three varieties outside this year is most favourable to them.—H. E. GRIEBLE.

**Saumarez Lodge, Guernsey.**—This garden being on a gravelly subsoil has suffered very much from the dry season. Small fruit fair crop. Strawberries very poor and soon done. Apples and Pears almost a failure. Plums none; they will not do here on account of the dry situation and exposure to the east winds. The severe frost we had during the past winter has left many open spaces. I have grown the Bouvardia in the open border for years with in the winter only a slight protection of ashes. Habrothamnus Newelli and Mandevilla on the walls were killed. Dracenas and Myrtles are also dead. We in Guernsey are not prepared for such frosts. This season will be remembered as the red spider year among Grape Vines. I believe many of the roots that were near the surface in the outside borders were killed by the frost, and want of the winter rains gave the red spider a footing.

Vegetables of all kinds were almost at a standstill until the rain came. Potatoes are a fair crop and of splendid quality; no disease.—W. CAMERON.

**Stoke Park, Slough.**—Fruit crops this season have varied a good deal in this quarter. The trees of most kinds blossomed well, but owing to the excessive dryness at that time the blossom was soon over. In some cases a good crop of fruit set, and continued to look promising until the excessive drought in, when every sort of fruit tree seemed to stand still. Small fruits did not suffer so much from the drought, and consequently I had the finest crop of Strawberries that I have seen for years, the fruit being large, well flavoured and beautifully clean. The earliest on a south border was the old and well-known Keens' Seedling, from one-year-old plants, followed by Vicomtesse and Sir Joseph Paxton, the latter being the finest of all main crop varieties with me. Auguste Nicaise bore heavily, but the fruit was poor in flavour and did not colour well up to the tips; consequently it has been discarded, as well as some others, including Waterloo, which has been given up owing to its colour more than anything else. For preserving I grow the old Grove End Scarlet, the finest of all for this purpose, but, being small, one is inclined to grudge the time it takes to gather it when a large quantity of it is required. I plant it (as well as all Strawberries) on deeply-cultivated ground heavily manured, and retain the plants for two seasons only, and from a small plot the amount of fruit gathered is astonishing. Gooseberries were a splendid crop; the hot dry weather seemed to bring out the flavour in the large varieties more than usual. For some years I have grown a few of the largest varieties amongst the Apple trees in the orchard and gathered the fruit from these green for the kitchen, and have found it a great saving of labour. Black Currants bore heavily and the fruit was of first-rate quality. Red Currants only a middling crop and fruit smaller than usual. Being on a gravelly subsoil, the bushes were almost burnt up in some cases; a breadth recently planted in a deeper soil promised exceedingly well. Raspberries have been very fine, being about the only fruit I could afford time to water. It is surprising what effect a slight sprinkling of nitrate of soda given Raspberry canes just as the fruit commences to colour has; the fruit swells to a large size, and, as far as I can see, does not injure, but rather improves the flavour. After the much-longed-for rain came, Apples swelled up to a large size and will be the heaviest crop I have had for years, as the trees are breaking down under the weight of fruit. Stirling Castle, Lord Suffield, Ecklinville, Warner's King and, indeed, a number of varieties, are quite loaded with fruit of good size; while Blenheim Orange, Cox's Ribston Pippin and other favourite dessert varieties are loaded with fine fruit, and now at this date (September 2) colouring beautifully. Pears are a very light crop on pyramids and the fruit much smaller than usual, a circumstance

partly accounted for owing to the enormous crops the trees produced last year and the drought this. On wall trees in most cases the crop is heavy and the fruit good. Plums the poorest we have had for years, Green Gage and Transparent Gage on walls being quite an exception, the crops being heavy and the fruit extra good both in size and flavour. Peaches on the open walls protected with a glass coping are very fine both in size and flavour; indeed, much too heavy, not having been thinned enough. The colour is all that could be desired. In some gardens near here earwigs have been a plague this season. On one old brick wall here that has been cemented over and wired, earwigs give very little trouble, whilst on another part of the same wall close by that has not been cemented earwigs are very destructive. My idea of growing Peaches outdoors would be to cement the wall and wire it, keeping the wires just far enough off the cement to allow tying the trees freely. A few years would repay the cost in the reduced labour compared with the old system of nailing, a system I have a decided objection to. All our trees are tied on this wall just before the blossoms open in spring, and with good raffia, which can now be purchased at very small cost, an active man soon gets over a tree. A wall so covered with cement is perhaps hotter in the middle of the day than a brick wall, but then I think it gives off, or at least does not absorb, moisture to the same extent a brick wall does. The wall here is 11 feet high and 55 yards long, the glass coping in squares 26 inches by 16 inches. At one time the glass was removed in the autumn after the fruit was gathered, and put up again before the trees blossomed in spring. The last four years the glass has remained permanent without any apparent difference to the trees, the result being a great saving in labour and expense, as taking down and putting up always meant some broken glass. From this wall I gather an enormous number of fine fruit, Crimson Galande, Stirling Castle, and Noblesse being fine, the last being more liable to mildew than the other sorts. Barrington planted two years ago promises well. Golden Eagle I planted some years ago, but found it too late in ripening to be of any use; besides the colour of the flesh was an objection. Apricots do not do well, and consequently are but little grown now. Cherries have been very fine, the trees having been well washed when the fruit was changing colour. Morellos I have never seen finer; this soil seems to suit the Cherry well both as standards in orchards and grown on walls where liberally treated. Mulberries are an immense crop and the fruit extra large. Filberts good. Quinces smaller than last season owing to the drought. The American Blackberries have been tried in several ways, but as yet without success, and in a garden not more than two miles from here they do very well and produce abundant crops of handsome fruit.

Early vegetables were good. Mid-season crops suffered much in the latter part of June and the first two weeks of July from the excessive heat and drought we experienced in this part. Since the rains came, crops have improved wonderfully, so that there are fine crops of most vegetables. Onions thinly sown and left unthinned are very fine, the bulbs not large, but very firm. Since adopting this system I have entirely got rid of maggot, and find the bulbs keep better during the winter. Carrots of the early type are treated in the same way. I had half an acre of Carrots sown in a field where the ground was in splendid condition at the time of sowing. The seed came up in patches; in some cases not a single plant appeared for 20 yards in a drill. Now every seed has come up and the plants are growing freely, clearly showing it was the want of moisture which prevented the seeds from germinating. Here we suffered more from the long-continued drought this season in the end of June and beginning of July than we did in 1893, making it a memorable season to many. Potatoes are an excellent crop and as yet free from disease, the last week or more of bright sunshine suiting the Potato crops well, and, indeed, all crops, the

Apple trees being magnificent. With us the ground is very dry again. On August 30 and 31 the thermometer fell during the night to 34°.—DAVID KEMP.

**Hardwicke Grange, Shrewsbury.**—I think we have to account for the very favourable fruit crop generally this year in many respects to the prolonged open autumn of last year. Up to Christmas we had open weather that helped to harden up the bloom-buds, which most assuredly were badly matured up to a late date through the want of sunshine during the latter part of summer and early autumn. Pears particularly were very short of buds. The crop of Pears, though under that of last year, is still a fair one. The Apple crop is good and clean and of large size. Plums are the finest I ever saw on standard trees. Nectarine Plum is one of the best varieties for standards and has been very fine. Gages a good crop on walls. Peaches with me are not a heavy crop, the buds having been killed by the two months' arctic weather we had at the beginning of the year. In other places I see the crop is fairly good. Of Apricots I can safely say there are none anywhere. The trees look healthy and much may be expected another year. Cherries of all sorts may be said to have been a good crop, the trees clean and fruit fine. Figs are mostly killed to the ground. I find Figs do best in paved yards against high buildings with south aspect. I have for the last twenty years had more or less good crops of the Brown Turkey variety. I may say no better situations than hard paved yards are to be found for Apricot trees. Filberts have been good. Strange to say, Walnuts are a very poor crop. Bush fruit has been good on the whole, Black Currants particularly clean and large. I find the old varieties are much the best; though not so large and sweet as some of the newer ones for preserving, they ripen all at once and we have done with them. Newer varieties are too late in ripening, and I find the same in regard to the Red Currants, the larger varieties die off so badly; no sooner has one a good plantation of them than one after the other the branches die off. Raspberries have done well. The Strawberry crop is excellent. I had a few, to me, new sorts a year or two since—Scarlet Queen, Crimson Queen, Competitor, Sensation, Empress of India, &c. The whole lot except the last-named is wanting in flavour and substance and other points that constitute a good Strawberry. They will all pass to the rubbish heap, and I shall keep to older and well-tried varieties. John Ruskin is my best early variety, being a few days later than the old Black Prince, which still leads by a few days. The very old Myatt's Eleanor maintains its character of being the very best late, and this gave me the finest crop I remember. Another old friend is Myatt's Eliza, not so late. This often goes under the name of Elton Pine, a very different Strawberry that I have not seen for thirty years or more. A friend of mine has had wonderful crops of this old Strawberry this year off eleven-year-old plantations.—J. TAYLOR.

## ROSE GARDEN.

### HYBRID PERPETUAL ROSES FOR POTS.

GIVEN well-ripened wood of these Roses, there is no time more suitable for potting them than the latter part of September. I have more than once taken this work in hand in the early part of the month just named, but it appears to have no advantage, but rather the reverse. For example, in a season like the present, with the exceeding great heat which we have experienced, the roots would very quickly dry up, and where this happens the Roses will be sure to feel it by and by; indeed, at no distant date many plants may die, and this by no means the fault of those purchasing the plants so much as those executing the order. Not that the nurseryman supplying the plants is to

blame, although his employes are the most guilty. Frequently when ordering dwarf Roses for potting up I distinctly state the purpose I require them for, and also make a special appeal that the roots be not subjected to any exposure either when being lifted or in the packing shed I have more than once further requested that the root end of the package be stood in the water tank, or the plants dipped in water. But in spite of many similar requests, the roots are often very dry when they come to hand. Whenever this happens I always soak the roots for half an hour in the water tank, and then heel the plants into some moist soil, and throw a wet mat or its equivalent over the shoots of the plants. In this way while lying in bulk any partly shrivelled wood may be more readily plumped up than could possibly be the case were the plants potted at once. The latter method would simply mean the greater exposure of the plants to drying influences just at the time when anything in this direction should be avoided. By soaking the roots and keeping the branches dark, any great mischief may be checked, and I think this method of plumping up the wood quickly has also the advantage of preventing undue saturation of the fresh soil in the pots just as the plants are potted. For instance, where the plants have suffered in transit and the wood has become somewhat shrivelled, the usual practice is to pot them at once and give a thorough soaking of water. And should the sun be powerful at the time or the wind of a drying nature, more water would be supplied to the roots and the syringe liberally used over the bushes. All this is very well in its way and helpful enough, but in the present state of the plants the roots cannot take up the moisture contained in the soil so readily, and the result is that it becomes unduly sodden. This, to say the least, is not giving the plant a fair start. And from experience I prefer, firstly, to plump up the wood and let the potting follow as soon as this ensues. Of course there should be no delay in potting them, inasmuch as the new roots will be waiting to push forth. Where such conveniences exist there is nothing to beat a deep pit into which to place these plants as soon as potted. In such places the first soaking of water given at the root will carry on the plants for some days, especially if lightly sprayed with water overhead daily and the frames darkened by mats. A week or so of such treatment as this is most beneficial in the quicker production of fresh roots. When this results, the lights and covering overhead may be dispensed with, unless it be a time of exceptional rain, when the lights may be placed over the plants, but admitting plenty of air.

A very great deal of the ultimate success or failure with freshly potted Roses of this class depends on the youthfulness of the stocks on which the plants are budded. Frequently old stocks that have been worked a second time without being replanted, while making fine bushes to look upon, are by no means the most desirable, certainly not the most successful. This is due in some degree, no doubt, to the increased number of the larger roots and the scarcity of the smaller fibrous roots, the latter much the more valuable for any purpose, more so when the plants are destined for pots. When potting up the plants, remove any damaged portions with a sharp knife and see that no buds exist on the stock. Where such have been, shave the eye level with the stock and so keep them in check. It is also a good plan with any feebly-rooted plants to nick the stem immediately below the ground line, in this way

securing more roots and greater vigour of the plants themselves. As a general rule, if the plants are of fair size, a pot 9 inches deep will be the most useful; indeed, I am inclined to favour pots deeper and wider at the base than these usually obtainable. The ordinary 8-inch pots are much too tapering and afford insufficient room at the bottom, where a large proportion of the best roots is found. A good sized pot for ordinary culture should be 8 inches in diameter at top, 7 inches at bottom, and 9 inches deep, measured inside in each case. Such a pot would take the roots of ordinary plants without crowding them into a mass, and permit of the addition of more soil below the roots than is the case with the ordinary 8-inch pot as usually seen. E. J.

**Rose Victor Hugo.**—This has been the best dark Rose of the year. It has not only grown well and flowered freely, but the rich dark velvety colouring has stood the late burning weather without getting seriously faded. As a garden Rose, I am disposed to regard it as superior to Prince Camille de Rohan, which I have hitherto looked upon as the best dark Rose.—J. C. CLARKE.

**Rose Lady Helen Stewart.**—I do not find this Rose any more subject to mildew than many others in the same line of colour. If it has one fault it is that it is not always a good grower. I do not believe it takes kindly to the Maunetti stock, as I have seen it in several places looking anything but happy, and on its own roots with me it is a poor doer. Its highly perfumed flowers make up for some of its other shortcomings.—J. C. C.

**Rose Dr. Grill.**—The coloured illustration of this Rose in THE GARDEN some time ago was, I think, instrumental in bringing to the front its merits as a pretty free blooming variety. It was raised as far back as 1886 and is most useful for cutting, being really perpetual and developing lovely flowers early, as well as late, in the season. The colour is an attractive shade of coppery rose. Although it is not large enough for exhibition, this Rose should be one of the first selected for garden culture.—S.

**Six really good Hybrid Teas.**—It was not until the National Rose Society saw fit to formally recognise this class as distinct from the Teas and Hybrid Perpetuals that we heard disparaging remarks in connection with them. For some time it has been my opinion that this class has a great future before it, and although they were very poorly represented, once not at all, in the classes set apart for them at the N.C.S. exhibitions, last summer saw some creditable boxes, eight stands having been put up. Augustine Guinoisseau, La France, Captain Christy, Caroline Testout, Gustave Regis, and Viscountess Folkestone are half a dozen varieties thoroughly deserving culture in any collection of Roses. It would not be difficult to choose a second six, in which case I should take Bardou Job, Cheshunt Hybrid, Grace Darling, La Fraicheur, Lady Mary Fitzwilliam, and Marquis of Salisbury. Cheshunt Hybrid and Bardou Job are two excellent climbers, the semi-double of the latter being one of our brightest glowing crimson. La France we all know, but, free as this old favourite is, its blush-white sport Augustine Guinoisseau is even more so. Caroline Testout and Viscountess Folkestone cannot be beaten by any Rose of their colour, whether we look for size, form, lasting qualities, perfume, or freedom in blooming. Most of the Hybrid Teas are simply grand for pot work, and I am sure that the new addition, Mrs. W. J. Grant, now returned to us from America under the name of Belle Siebrecht, will soon become one of the most popular of all. Very much of the opposition to these as a separate class arose from the fact that for many years La France and Captain Christy were placed with the H. Perpetuals, and also because the raiser of Gloire Lyonnaise sent it out as the first yellow

H.P. This could only be as a trade advertisement, a yellow H.P. having a novel sound. The raiser admits it to be a cross between Baroness Rothschild and Mme. Falcot.—R.

**Roses that do not droop.**—For the first time during a somewhat lengthened experience I was recently asked to furnish the names of any Roses whose flowers do not droop. The majority of the H.P. Roses have a tendency to hang down their heads, and are therefore unsuitable for cutting. This was the reason assigned for making the request I have alluded to. Unless I am very much mistaken, the querist will not get a great amount of sympathy from readers generally if it is intended to imply, as I think it is, that a great proportion of the Roses we cultivate have this defect. If we were to grant this for a moment we should have to exclude quite two-thirds of the very best flowers, and our gardens would be all the poorer for encouraging such a taste, as there is only one type among the H.P.'s that has flower-stems rigid enough to support the bloom erect from the time it opens until it fades. The experienced reader will understand that I am alluding to such varieties as Baroness Rothschild and Merveille de Lyon. But really as regards any of the others, I do not see that there is serious cause for complaint. If there is any cause, it must arise from one of two reasons—indifferent cultivation or want of judgment in selecting the flowers of a suitable age for decoration. This short note may perhaps be the means of our hearing from readers whether there are any more who entertain the same opinion as my correspondent; if so, it would be of service if they would kindly give the names of any Roses they have found to have this defect. From information so furnished we may be able to compile a list of non-drooping varieties that would be useful to many readers.—J. C. CLARKE, Taunton.

## GARDEN FLORA.

### PLATE 1035.

#### SELF-COLOURED LATE TULIPS.

(WITH A COLOURED PLATE OF, 1, T. BOUTON D'OR; 2, T. PICOTÉE.\*)

The genus *Tulipa* has naturally a very wide distribution, since, like the *Narcissus*, its various species or phases range from Britain and Southern Europe to N. Africa, Persia, the Caucasus, Turkestan, N. India, and Japan. The exquisite little yellow Wood Tulip (*T. sylvestris*) is possibly a native of a few localities in Norfolk and Suffolk, where it affects chalky and flinty places, but it is also easily and abundantly naturalised in woods, copses, and meadows elsewhere. It is now and then to be seen in the Christchurch meads at Oxford, though they are more famous for the chequered purple or white Fritillaries that nod and flutter amongst the fresh young Grass of April or early May.

In Europe there are the shapely little pink and white Lady Tulip of Clusius (*T. Clusiana*); *T. Oculus solis*, red as a soldier's coat, with a golden halo around a black disc or eye at the base of each of its petals. *T. præcox*, which some consider but a form of the last-named, is also found in S. Eastern Europe with one or two others, but the focus spot of all the more gorgeous kinds is in S.E. Europe and Central Asia. The splendid *Tulipa Gen'eriana* is naturalised in fields and vineyards in one or two localities near Florence, but without a doubt the bulbs were originally introduced there, or more probably escaped from old gardens. The Tulip is, of all our garden flowers, a

1

HERBARIUM OF THE  
UNIVERSITY OF TORONTO

great and beautiful mystery in many ways. Its history is uncertain, and all the wild kinds change so much under garden culture, especially if propagated from seed, that they become scarcely recognisable as compared with their natural parents. Then their habit of altering their colours or "breaking" years after they are reared from seed is, so far, an unexplained mystery. So far as I know, there are no authentic hybrids between any two distinct species, but cross-bred varieties of both *T. Gesneriana* (late, or florist's Tulip) and *T. suaveolens* (early Tulip) are abundant. *T. macrospila* is supposed to be a wild hybrid between *T. Gesneriana* and some other species.

All the seedling Tulips seem originally to have been raised in Flemish and Dutch gardens, and the first Eastern Tulips are said to have reached England from Vienna about 1578.

know, the origin of this variety is unknown, but perhaps some of our Dutch friends—Krelage, De Graaff, or Van Tubergen—may enlighten us as to the early history of Bouton d'Or and of its dainty companion on the plate, which has come to us of late years under the name of Picotee. What Picotee really is I do not know, whether a white, rose-edged form of *T. Didleri*, *T. fulgens*, or merely one of the ubiquitous phases of *T. Gesneriana*, or an especially late-blooming form of *T. suaveolens*. But it is quite sufficient to know that both the varieties here represented are good strong growers on all moderately light and warm soils. Bouton d'Or increases by offsets very rapidly, especially if the roots are taken up and cleaned in July ready for replanting in September. I have had large clumps of it in the Trinity College Botanic Gardens for ten or twelve years unmoved. These

a few years earlier. Gerard, Parkinson, old John Rea, and other early English gardeners all wax most enthusiastic over the Tulip—the flower of delight, or, as an old author says: "The Tulip is a queenly flower, and asketh a rich soil and the hand of a master."

To see broad beds, or even large clumps, of such brilliant kinds as *T. Gesneriana*, *T. fulgens* or *T. macrospila* amongst fresh young grass, and with a suitable hedge or other dark background, is to see a vivid picture of the finest and most satisfying of all colours. I once saw a few hundred bulbs of *T. Gesneriana*, the finest and latest crimson kind, flowering on a turf bank, backed by a hedge of Sweet Brier, Yew, Clematis montana and Quince bushes in full bloom, and the effect was almost indescribable. No other flower—not even Jacoby Geranium or the Pan Anemone—ever gives such a rich and intense bit of colour. To see any of the pure yellow or crimson Tulips in flower amongst greenery when the sunlight passes through their cups is one of the most satisfying delights you can have in a garden—not sweeter than milk-white Hawthorn, nor than old gnarled Apple trees in full bloom, but gloriously regal all the same.

There is another picture in the forest county of Sussex that I well remember in May, when a few hundred, or thousand may be, of the Wood Tulip jewels the young grass beneath an Oak tree on the fringe of a wood. Lovely as are its golden buds as seen in the grass, they are even more beautiful as cut by the hand and placed in fresh water to open their flowers indoors. Even the lemon-scented Mexican *Cattleya* is not more exquisite in soft colouring or more subtle in its dainty curvature of stalk and petal as thus seen in a vase quite near to the eye. Those who grow the best of hardy bulbous flowers need not envy the possessors of Orchid houses. Squill and Daffodil, Lily and Iris, Crocus, Snowdrop and Narcissus are all lovely flowers, but for royal pomp and splendour one must always have the best of self-coloured Tulips, both species and varieties, in quantity to flower in May.

F. W. B.

Late-flowering Tulips, forms of *T. Gesneriana*.

To Vienna, Tulip roots had been sent or brought by Ogier de Busbecq, the Flemish ambassador at Constantinople, about the year 1562. In his well-known "Turkish Letters" Busbecq wrote: "The Tulip has little or no smell: its recommendation is the variety and beauty of its colouring. The Turks are passionately fond of flowers, and, although somewhat parsimonious in other matters, do not hesitate to give several aspres for a choice blossom."

Of late years a strong appreciation has arisen for self-coloured late Tulips as opposed to the striped kinds, and one of the latest and most effective of all the late yellow kinds is Bouton d'Or or Buttercup, so faithfully shown by Mr. Moon in the coloured illustration. Its golden buds and blossoms are very strong and pure in colour, with jet-black anthers inside the cup-like perianth segments. So far as I

flower well and regularly every May-tide, and in half-shady places the latest blooms last well into June. How it came here I do not know, but it has been here considerably over a quarter of a century, along with *T. sylvestris*, *T. Golden Eagle*, and several very beautiful old forms of *T. Gesneriana*, including the rich old treacle-coloured kinds. Just now there is, as I have hinted above, a revival or renaissance in favour of the best of old late garden Tulips, and for such noble self-coloured species as *T. Gesneriana*, *T. Gesneriana Strangwaysi*, *T. fulgens*, *T. retroflexa*, *T. macrospila*, *T. Golden Crown*, *T. Golden Eagle*, *T. Billietiana*, *T. vitellina*, and a hundred and one self-coloured forms of the Flemish and old English garden Tulips that have been grown in England since the days of Elizabeth and Shakespeare, and in Belgium and Holland no doubt for at least

## THE WEEK'S WORK.

### KITCHEN GARDEN.

PLANTING CAULIFLOWERS.—It is now high time that the first batch of Early London, Walcheren or Early Erfurt intended for supplying heads at the end of May were transplanted. Where handlights are still used a great advantage is gained, as there is no root-disturbance or check given by lifting in spring, and the plants can as easily be protected in sharp weather as in frames. If the ground was well trodden and the lights placed in position as advised a short time since, the soil should now be in a nice firm condition to receive the roots. Where the plants have been pricked out into beds, they may with care be lifted with a fair amount of soil adhering and should feel the check of removal but little. If rain has not fallen lately, give a gentle soaking with a rose the day previous to planting and choose a calm dull day for the operation. Avoid the common practice of laying out many plants at one time; rather repeat the journey, and lay out say half a row at once, otherwise the roots, which are very delicate, are apt to suffer. Most gardeners place five plants in each light, one at each of the four corners and one in the centre—a very good number, as then they can be reduced to three in the spring and allowance is made for loss by grubs or bolting. Plant firmly and sufficiently deep to prevent the plants swaying to and fro by autumn winds, this ruining many lots of plants in exposed gardens. Planting completed, give a gentle watering to settle the

soil round the roots, and if the weather is open and nights warm, leave the tops of the lights off for the present. Should, however, frost or rough weather set in, they will be better left on, arranging them crossways so as to admit a portion of air. If the plants have to be drawn from the seed bed, avoid the largest, choosing rather medium-sized ones with perfect centres. The next thing to be considered is the protection of a sufficient number of plants in frames or pits for transplanting for successional supplies in June. The smallest plants are the best for this purpose, provided they are sound and well rooted, as the shelter of the frame yard frequently induces Cauliflowers and Cabbages to grow too freely and become ungainly by March or April, especially should the winter be mild. Both in the handlights and frames a sharp look-out will be needed for the troublesome underground grub which eats the plants off just beneath the soil. Should the weather set in wet and slugs make their appearance, dust fortnightly with a mixture of lime and wood ashes. A little of this mixture sprinkled over the surface of the soil will act as a preventive to mildew and leaf-rotting. Any spare plants left in the seed-beds may be pricked out into rows in a sheltered nook or corner where they can easily be protected in sharp weather. In ordinary winters and on warm soil they will sometimes survive and be more useful for spring planting than frame-protected plants, should the latter grow too large.

**GLOBE ARTICHOKE.**—Owing to the destruction by frost amongst the roots of this vegetable last winter, many were induced to sow seed in spring to raise a new stock. I advised that when transplanted they should be grown on a spare piece of ground, in order to prove their value before putting them into the permanent rows, as, generally speaking, a very large percentage of them is worthless. Select those worth retaining and plant at once on good rich land; give a good mulch of Braeken or dry oat straw, but by no means use decayed manure, as this only makes matters worse. On heavy soils it will be safest to wait until spring before planting these seedlings, mulching, as advised above, where the plants stand. Those who just saved their stock last spring will, if their soil is at all strong and retentive, do well to sever a number of the healthy young offsets some time during this month and pot them up into, say, 6-inch pots, giving them the shelter of a cool pit or deep frame, where a covering can be thrown over in sharp weather. These will increase in size and, if planted out in March, give finer heads (even if a little later in the season) than garden-established clumps. Some gardeners have abandoned mulching the old stools in the open, thinking that it made matters worse; but if light material is used, and this is removed in mid-winter and replaced with fresh, a wet mass round the collars is avoided. It is when decayed manure is used that mischief follows in periods of much wet and frost combined. Frost being already upon us, those who value the late heads had better throw a little canvas or some garden mats over the plants when frost threatens: a few rough stakes driven into the ground will support the mats. Liquid manure may still be given to plants that are at all weakly; on stiff soil, however, no more moisture should be given.

**MUSHROOM HOUSE.**—In a previous calendar I gave instructions concerning the preparation of an early bed, and this will ere now have been spawned and soiled. The house, hitherto warm enough without any artificial heat, will now need a gentle pipe warmth on cold nights to keep up a temperature of 55°. As soon, however, as it is seen that the spawn is in active operation, a fall to 50° may be allowed, this figure suiting the secondary and main crop beds better. Should the heat of the early bed show signs of falling, give a fair covering of dry oat straw, and, provided the material is fairly moist, do not water the bed until the young Mushrooms make their appearance. Manure from corn-fed horses should be collected each morning, for, as a rule, by the time sufficient has been procured and gently sweated it is time to make up another bed. Some people throw the

droppings into a heap and allow them to remain unturned for some days in order to save time, but the practice is a bad one, as by such violent sweating much of the ammonia required for producing and nourishing the young Mushrooms is wasted in evaporation, neither do such beds last so long. Throwing it into a ridge and turning it every morning is by far the best plan, always letting that portion which was at the outside of the heap be worked into the centre next time. The long straw should be removed as the manure is gathered, but the short should be left in to assist in keeping it open, and thus encourage a freer working of the spawn. A very common mistake in Mushroom houses is to saturate the walls and floors every day with water. This creates a close, steamy atmosphere, which quickly turns the young Mushrooms black and hinders them from swelling. The best plan is to lightly syringe the paths and walls each morning, and no more. Insert the spawn when the heat of the bed has fallen to 90°, as if left till cooler, the disturbance of the surface and the opening and shutting of the doors often lower the temperature another 10°.

**FORCING FRENCH BEANS.**—It may seem premature to speak of this work, but a batch sown now and brought forward in a moderate heat only will not be in a bearing state until the outdoor protected and cool frame-grown lots are past. I usually sow about this date, having relied principally on those good old varieties Osborn's Forcing and Sion House. Where the plants can be treated to plenty of light and air and a sturdy growth secured, 8 inch pots may be used for this sowing, but all succeeding batches should be grown in 6-inch pots and feeding resorted to. A few gardeners grow their Beans in shallow home-made boxes, and a capital plan it is if room can be found for them. It is astonishing in how little a quantity of soil Beans will thrive, and it does not become sour, as does a potful, if once over-watered. Very little water will be required until the Beans appear through the soil; indeed, rule-of-thumb watering must be avoided, or basal rot and death will quickly ensue. Sow enough seed to allow of thinning out the plants when an inch or so high, but do not upon any account top dress with soil, as the idea that Beans emit surface roots is erroneous. In turning out old batches of forced Beans that have been top-dressed I never once yet found that any new roots had entered it. A house kept at 55° to 60° during hours of darkness will suit French Beans at this time of year, 60° being the minimum temperature a month hence. In preparing the pots see that plenty of drainage is placed in the bottom; the slovenly plan of one crock over the hole and a few leaves is not conducive to a free and healthy growth, especially in the depth of winter. J. CRAWFORD.

#### FRUIT HOUSES.

**PEACHES and NECTARINES.**—After the genial rains the fruit-grower will now be busy lifting and transplanting. Trees that have grown too strong and cast their buds or fruit will well repay for lifting. Trees, the leaves of which curl and mildew badly, may be cured by careful lifting, giving suitable drainage, and bringing the roots near the surface. Young trees growing grossly need the strong roots shortened back, and older trees inclined to grow coarse must have similar treatment. In lifting old or young trees it should be first ascertained if the roots are thoroughly moist; if at all dry, by removing a portion of the surface soil, making a basin, and well saturating the roots before lifting, there will be less danger of injury to surface roots. After the transplanting another good watering will cause new fibrous roots to form, and prevent flagging. In lifting always have plenty of room to work freely; open a trench 2 feet wide at least 3 feet from the tree, and throw back all soil taken out, well working the soil from the fibrous roots with a fork, and likewise getting well under the trees, cutting the strong coarse roots with a sharp knife. Endeavour to preserve a solid ball of earth and roots

close to the stems; do the work as expeditiously as possible, and, should the weather be bright, give the trees a moistening overhead afterwards. Trees removed to a distance should have the roots and ball of earth well supported by mats, boards or a handbarrow, as by doing this work carefully there will be no loss of fruit next season.

**COMPOSTS and DRAINAGE FOR TREES.**—It is important to have plenty of suitable compost for trees to be lifted and replanted. The Peach and Nectarine revel in an open compost which is readily warmed by the sun, and, of course, in tenacious soils drainage is an important factor. Great improvement may be made in wet soils by ample drainage and raised borders. On the other hand, in such seasons as we have just passed through I have found trees in a light flinty soil starving from the want of food and moisture, and have seen the necessity of having the Peach border slightly lower than the adjoining border to conserve the moisture. It often happens where a liberal mulch is given that the soil is in time so much raised that the trees do not get the full benefit of rains or watering; it is then necessary to remove a portion of the surface soil down to the roots, thus reducing the height. Replace the top or richest portion of the soil. If done as soon as the leaves have fallen it will benefit the trees, and sucker growth may be removed at the same time. It will be scarcely necessary to point out the evils of too much manure for the newly-lifted trees. Excess is the cause of strong root growth and much better wood is secured by using a suitable compost. In soils deficient of lime, chalk or old mortar rubble is invaluable to the formation of a hard, fruitful growth. In place of manures mixed in the soil, burnt garden refuse, wood ashes, and road scrapings are of great assistance in lightening a heavy wet soil, and where it can be obtained, good loam, which has been stacked for a little time, will be of great benefit to young trees. Food can always be given as a surface dressing at any season, and in no case (unless the soil is poor and much impoverished) should animal manure be placed under the roots. Drainage should be freely used in stiff heavy soils, using brick rubble and making a mound of the same before planting young trees. Cover the rubble with thick sods of freshly-cut turf, grass side downwards.

**APRICOTS UNFRUITFUL.**—Much that has been said of Peaches and Nectarines is applicable to Apricots. I like to lift Apricots before the leaves change colour, to retain the foliage as long as possible after lifting, and thus get new root action before severe weather sets in. Apricots which fail to make good wood and fruit freely will well repay attention, adding new material for the roots to work in. I have had trees which were valueless give very heavy crops in two seasons after being lifted. But my remarks must not be taken to infer that lifting will cure all evils. Still, in the case of unfruitful trees I would strongly advise more attention to the roots as early in October as possible in poor soils, giving food as advised for Peach trees with the addition of bone meal to impoverished soil. The renovation, if undertaken in time, will often save the trees. In soil requiring drainage apply it freely, as Apricots delight in copious supplies of water.

**PLANTING NEW TREES.**—The compost already advised, namely, good turfy loam, should be used freely for young Apricots, as by using suitable materials the trees make a good foundation and are then in better condition to resist disease. Early planting is also important with many stone fruits, especially in wet soils. Those who require the hardest Apricots must rely upon such sorts as Large Early, a free grower; Hemskirk, a similar variety to Moorpark and the best of all, rather subject to canker, but a robust grower; Breda, small, but reliable; Large Red, somewhat after Large Early, and Powell's Late, a hardy late kind less subject to disease than many others. This is a small list, but I have found these varieties succeed when others have failed. In planting, firm the roots well, and afterwards give the sur-

face a light covering of short strawy litter, first watering thoroughly should the soil be dry.

**FIGS.**—The crop on open walls has this season been very good where the trees escaped injury last winter, and now the fruit is cleared there should be no delay in preparing the trees for the winter, as I attach more importance to thorough ripening of the wood than to coddling or covering to preserve half matured wood. Much may be done now to expose the wood required for next season's fruit. All Figs visible or of any size are now useless. It is the embryo fruits at the points of the shoots which require light and air. All useless fruits should now be removed, also shoots and lateral growth which cannot be attached to the wall. Trees that were badly cut early in the year by frost if attended to as previously advised will have made good leaders. Keep these close in to the wall, removing any useless wood or late fruits, also any new sucker growth from the base.

**CROWDED OLD FIG TREES.**—These are often seen a mass of old, thick crowded wood with a scarcity of good fruiting wood. Two ways are now open to redress the evil, one now, another next spring. If these trees are root-pruned now and the best wood given wall shelter, a lot of the old wood may be taken out next April. In root-pruning old trees do not be too severe the first time, but allow a fair space from the wall. Give the roots left the new soil advised above with some bone-meal, using plenty of old mortar rubble, and ramming the new compost firmly.

G. WYTHES.

## ORCHIDS.

### ONCIDIUM AUROSUM.

I HAVE a large plant of the above. I have had it for three years, and its former possessor had it for four years. During the seven years it has never flowered. It was in an 8-inch pot, but this spring I put it into a 12-inch one. It looks all right and the bulbs are nice and large. If you could tell me what to do with it I should be glad. I have been advised to break it up.—**JOHN C. McLEAN.**

\* \* The cultivation of *Oncidium aurosium* presents no special difficulty—in fact, it is one of the easiest Orchids to grow. As you give no details of your cultivation I cannot say what is wrong in your case, but the treatment given below, if attended to, should enable you to both grow and flower it. *O. aurosium* is one of the larger-growing members of the genus, and one that produces long branching panicles of flowers, as many as fifty or sixty on a spike being by no means uncommon. Each blossom is about 1½ inches across, the segments bright golden yellow, with a few reddish brown spots in the centre of the flower. Being a vigorous grower, it likes more pot-room than others in the genus, allowing about a couple of inches at least around the pseudo-bulbs. Good drainage must be given, this being well covered by a thin layer of rough Moss. Over this the compost may consist of equal parts of peat and Sphagnum Moss, and plenty of rough lumps of charcoal or potsherds must either be mixed with this or introduced as the work of repotting proceeds. The plants need not be set very high above the rim of the pots, but are better for being slightly elevated, as this ensures immunity from the effects of water collecting about the bases of the pseudo-bulbs. If the old roots on the pseudo-bulbs are plentiful and the compost before repotting was not in too bad condition, it is unwise to disturb them more than is avoidable, but if, on the other hand, the roots are found to be decayed with few live ones in a sour and close mass of half rotten peat, then they should be washed quite clear of this and only the best of them retained. In such a

case it will also be best to use a smaller pot than has been advised for healthy plants. The compost being ready and the pots well cleaned and dry, bed this around the plants firmly, but not too close, laying the peat and Moss and the crocks in alternate layers and using a blunt-pointed dibber to fix it. The pots having been filled, trim off all ragged ends neatly and return the plants to the growing quarters. This should be in a temperature only a little, if any, above that of the *Odontoglossum* house, or say a structure kept as cool as possible by heavy shading in summer, the minimum winter temperature being about 50°. The lightest and most airy position should be given the plants, and after repotting they must be carefully watered at the roots until the latter are again well on the move, then increasing the supply by degrees as the new growths develop. If you wish to propagate the species, you may divide it as recommended, but this would certainly not predispose the plants to flowering. If the pseudo-bulbs on your plant are quite finished up, you had better reduce the supply of water at the roots for a time, but not sufficiently to cause the pseudo-bulbs to shrivel. This may have the effect of causing the plant to flower, but the species with me has never given any trouble in this respect. Endeavour to keep it quite at rest till the spring, only just enough water to keep the bulbs plump being needed; then when the growths start, grow it as quickly and strongly as possible, and most likely you will be favoured with flowers in abundance in the autumn. With all these tall-growing *Oncidiums* there should be a distinction made between the growing and resting periods, giving an abundant supply of fresh air, and for the species in question a cool house. By comparing this treatment with your own you may possibly see where you have gone wrong. The most frequent mistake made by amateurs and beginners is a too close atmosphere, especially during the growing season.—**H. R.**

**Aerides affine.**—This is a pretty little species and very free-flowering when well managed. The best position for it is in the *Cattleya* house, where the growth is more likely to be well ripened than if kept in the East India house. The erect spikes are very closely set with the pretty little pink and white blossoms, and are produced from the axils of the leaves near the top of the plant. Small baskets or shallow suspended pans may be used, and not too much Moss should be placed about the roots.

**Epidendrum Wallisi.**—This belongs to the section with upright distichous-leaved stems, growing about 2 feet high and producing terminal racemes of flowers. These are about an inch across, the sepals and petals yellow, with dots of crimson, the broad spreading lip white, with lines of a faint purple tinge. This species requires liberal treatment to obtain good results; it must be potted firmly in good peat and Sphagnum, and grown at the cool end of the *Cattleya* house. The plants never seem entirely at rest, and should be let have their own way in this respect. A liberal supply of water must be given all the year round, only a little less being needed during winter than in summer.

**Oncidium Harrisonianum.**—Where small, but brightly coloured flowers are appreciated, this pretty little species will probably find many admirers. It is a very old species, having flowered as far back as 1832 in the collection of the lady whose name it bears, yet it is not so common as many newer kinds. The pseudo-bulbs and leaves are small and grow in clusters, and the spikes are produced rather freely in autumn and sometimes again in spring. These attain a height of about a foot, the flowers being rather closely set upon them, plants with half-a-dozen or more

spikes being very attractive. Each flower is about half an inch in diameter, bright yellow, spotted with brownish-red. The pots used for this *Oncidium* must only be large enough to take the plants easily, as it is not a strong-rooting kind. Three parts of Sphagnum to one of peat will grow it well, and the drainage must be about two-thirds of the depth of the pot. It winters best at the cool end of the *Cattleya* house, but during summer it may be placed with the *Odontoglossums*. Plenty of water will be needed in the small pots advised above, so the compost must be frequently renewed, at least on the surface, or the requisite amount of air cannot reach the roots, a very important detail in the management of these small-growing kinds.

**Masdevallia polysticta.**—This species does not, I think, usually flower in autumn, but I recently saw a nice plant in full bloom. The blossoms are small, but plentifully produced, occurring on racemes of about five or six. The sepals are rosy white, profusely spotted with purple, and the flowers last a long while in good condition. It is a Peruvian Orchid, introduced in 1874, and is best grown in small pots or pans in a mixture of peat fibre and Sphagnum. The early spring is the best time to repot.—**R.**

### PLEIONES.

WITH the flowering of *Pleione lagenaria* the season for these pretty Orchids commences, lasting from now until February or March, and serving to brighten up the cool house during late autumn and winter. In the structure of the flowers these Orchids closely resemble *Celogyne*, to which genus modern botanists ascribe them. They are, however, so different in habit of growth, manner of flowering and other details, that they will doubtless continue to be better known by the old name. The pseudo-bulbs of *Pleiones* usually last only one year, the old ones decaying as the new ones are being formed. They are all deciduous, producing the flowers along with the young growth. A distinct growing and resting season must be observed with these Orchids, and as they commence to grow at different seasons of the year, they require also to be repotted at different times. All of them are best attended to just as the flowers have faded. It is usual to repot the plants annually and to shake away all the old soil from about the roots, as with deciduous *Calanthes*. The best compost for them is two-thirds of nice fibrous yellow loam to one of peat, adding to this enough chopped Sphagnum and finely-broken crocks to make a light and elastic-feeling mixture that, while holding plenty of moisture, will soon run dry. Many growers are in the habit of filling large shallow pans with the bulbs, and in this way a good display can be made, though for many reasons smaller pots are preferable, and I never use any larger than 5-inch. By planting in this size it is easy to arrange the plants among small pots of Ferns, which hide the great defect of *Pleiones*, viz., the fact of their flowering upon the leafless pseudo-bulbs. Growing small seedling Ferns in the pans has also been tried, but, as far as I have seen, with no great advantage, these being usually kept too dry after the pseudo-bulbs of the *Pleiones* are finished and before the flowers appear, losing most of the fronds. Besides this, the roots of most Ferns appear to have a living effect upon the Orchid compost, spoiling its open condition, and for this reason alone I never care to see them in Orchid pots or baskets. The plants having been shaken free of the old soil, the roots may be shortened back, but not all cut off, as they help to steady the bulbs in their new position. Care must be taken in repotting not to injure the young growths, and the base of the old pseudo-bulbs

may just rest on the top of the compost, which should be kept rather higher in the centre of the pot than round the rim, the flowers showing to greater advantage this way. If any new roots are being emitted before the plants are potted, even more care than before is necessary. The roots are really the most important point to be studied, and providing them with a suitable holding and careful watering are of even more consequence than the temperature. They must be placed in the *Cattleya* house for a time after potting, and extreme care is needed in watering, too much or too little being equally injurious. When, however, they are rooting freely a full supply may be given, and the plants will thrive in a cooler house. They all enjoy plenty of atmospheric moisture, and a light position is essential. As soon as the pseudo-bulbs are matured, lessen the water supply a little, giving less and less as the foliage turns colour and falls. Then when the flower-buds are seen to be again pushing increase the supply, as this will strengthen the plants and cause the flowers to be of better substance and colour, therefore lasting longer and making a better display. To propagate *Pleiones* the plants must be grown as vigorously as possible, attending carefully to every detail of their culture. Then a large percentage of the pseudo-bulbs will produce two new growths, the resultant pseudo-bulbs being afterwards potted separately. The species named below are among the best known and most useful kinds, and will make an interesting collection.

*P. HOOKERIANA* is a charming spring and early summer-flowering kind, requiring rather different treatment from the other kinds. It thrives best in shallow pans hung up close to the glass in the cool house. The manner of flowering is also different, the blossoms being produced along with the young growth and not preceding it. These are of a bright rose colour excepting the lip, which is white with a few reddish blotches near the base. This species was discovered by Sir J. Hooker in 1878 at great elevations in the Himalayas, where it grows on the mossy trunks of trees.

*P. HUMILIS* is one of the most beautiful kinds in the genus, the lip being especially attractive. This is very large and spreading in front, where it is beautifully fringed. The colour is pale lilac or rose, striped with purplish crimson and suffused with yellow. The sepals and petals are in the type of the purest glistening white, but in the variety tricolor they are very light rose. A native of Northern India, introduced in 1850.

*P. LAGENARIA* is a large flowering and very effective kind, and one of the best known. Its blossoms are produced during the present and next month on one or two-flowered scapes. The sepals and petals are rosy lilac, the lip rather paler in ground colour, prettily marked with crimson and yellow. A native of the Himalayan Mountains, whence it was introduced in 1850. A very similar kind is

*P. PRÆCOX*, which is, however, usually deeper in colour, and its flowers are produced in winter. It is a widely distributed species in Northern India, growing at an elevation of 5000 feet or 6000 feet. A deeply-coloured and large-flowered form of this kind is *P. præcox Wallichiana*, which is sometimes classed as a distinct species.

*P. MACULATA* is another variable and beautiful kind, thriving well in an intermediate house. Its blossoms are about 4 inches across, pure white in ground colour, the lip being prettily spotted and blotched with crimson, and having several yellow ridges running lengthways from the column. Also a native of India, introduced in 1850. H.

**Flowers of Egypt.**—The oldest herbarium in the world is to be found in the Egyptologist Museum at Cairo. A few examples from Cairo may be seen at Kew. It consists of a large number of wreaths and garlands of flowers collected

together from ancient Egyptian graves. These floral remains are practically all in a well-preserved condition. In most of the flowers those parts which have been protected by an outer covering are, in spite of their extreme delicacy, perfectly intact, while their colours have been preserved in a remarkable manner; it has even been found that some of the blossoms by immersion in water showed that they still retain possession of their colouring matter. All the flowers are such as grow to-day in Egyptian gardens, and were used as votive offerings, as we offer wreaths and Palm leaves to-day. The most interesting feature of these collections is their great age. Some of them were immured in sarcophagi so far back as 2500 B.C.

**Railway station gardens.**—A correspondent's notes on flower gardening at railway stations reminds me of the beauty of some of the station gardens on the Great Eastern line

be so gay and attractive, while in others they are dull, unattractive, and apparently neglected.—J. C.

## TREES AND SHRUBS.

### THE FLOWERING ASH.

(*FRAXINUS ORNUS*.)

THIS is by no means a rarity, being a native of the south of Europe, and introduced as long ago as the early part of the last century. It is a small or medium-sized tree, in general character like the Ash, but less vigorous in growth. The principal distinctive character—from whence the name is derived—is the large open plume-like panicles of flowers, which are of a greenish white colour, very sweet scented,

Spikes of the Flowering Ash (*Fraxinus ornus*). From a photograph by Miss Armstrong, Monkstown, Dublin.

between Chelmsford and Norwich. Not only are they gay, but great taste is displayed in the arrangement of the beds and borders. I have often wondered how the station-masters manage to winter the Geraniums, as in nine cases out of ten the only glass accommodation they have is a two-light frame, often made by themselves. Yet after the severity of last January and February, there are the Geraniums as gay as ever. At a few places I noticed several tree trunk ends covered with their rusty bark utilised for Geraniums of larger size, while Petunias and Lobelias were hanging gracefully over the sides. *Tropaeolum canariense* and the ordinary mixed Nasturtiums were trained on strings, so as to cover many an unsightly outhouse. Hops, Virginian Creeper, and Clematis Jackmani drape many a porchway, and in a few instances the sunny front of the station-master's house is adorned with *Ampelopsis Veitchi* in its autumn garment. It is strange that railway gardens in certain districts should

and borne in great profusion about the end of May. Like the common Ash, the European *Ornus* succeeds best in pretty good soil, and in a moderately moist rather than a very dry situation. When young it is of regular outline, and blooms so freely even when about 15 feet high that the plant is thickly studded and the scent is apparent for some distance around the tree during sunshine. The habit of the tree alters with age, as it then assumes a far more open character, like the common Ash.

**Medicago arborea.**—This little shrub is now flowering freely at Kew, where there is a bush trained upon the outside wall of the cool division of the Orchid house. It is a native of Italy and allied to the Broom family. Its flowers are of a deep yellow colour, and borne profusely in crowded heads all along the shoots.

## KITCHEN GARDEN.

## STORING POTATOES.

DURING the past two winters the severe frosts experienced have done immense damage to the Potatoes stored in sheds, pits or clamps in the fields and other places. In some cases the loss has been very serious, nearly the whole of the Potatoes having been more or less frosted and useless for sale or home use. In face of this loss, it may be useful to indicate how the present magnificent Potato crop can be protected. It is only in the best arranged gardens that proper root-sheds are provided, and those who are less fortunately situated are obliged to make the best use of the means at their disposal, utilising any spare or unoccupied sheds that are frequently far from frost-proof, or, failing such structures, the Potatoes are placed in the ordinary pit or clamp. Where sheds are available, they are much more suitable for storing the Potatoes than in the open for many reasons. Amongst these is the ease of sorting over in bad weather when it is unfit for the labourers to work outside, this timely removal of rotten or decaying tubers stopping further loss; the Potatoes are also dry and can be taken out at any time without any inconvenience in either frosty or wet weather. In many country districts last winter there was practically a Potato famine, because they were in a band of iron, as it were, the soil over the "bury," as it is termed in this part, being almost impenetrable, and no one would open the "bury" lest the frost should enter and spoil the whole; consequently prices ruled high until a change occurred. All this inconvenience is avoided in sheds, and even if these erections have thin walls and do not keep out much frost, the Potatoes can be made perfectly safe by a good lining of straw round the sides, underneath and over the top. I have kept Potatoes in excellent condition in such a shed, and which have compared very favourably late in the spring with those stored in clamps. Not only so, but they have been later in starting into growth. However, when there is a large quantity of Potatoes grown it is generally a case of "Hobson's choice," and they have to be put in clamps outside. After trying various sizes, I find a width of 4 feet at the bottom best, as the Potatoes generate less heat and keep much sounder than in wider heaps; the length does not signify, as it may extend for hundreds of yards if necessary. The usual practice is to select a piece of land with a gentle slope, then dig out the soil about a foot deep and the proper width, shovelling out all the loose soil. Some growers put their Potatoes in at once and cover over with straw, but I prefer to have a layer of straw underneath and fill in then with the Potatoes, bringing them up to a pointed ridge, and then cover with a 6-inch layer of straw or bracken, placing on that at least 6 inches of soil and beating it firmly. Before the soil is put on, a drain pipe fixed at the summit of the Potatoes at every 6 yards or 8 yards will be of service, by allowing any sweat to escape. These pipes will stand out through the soil, and a piece of straw stuck in will keep out a lot of wet, and allow the internal moisture to evaporate as well; in a few weeks time a brick or piece of slate can be put over the orifice, as all sweating will then be over. It is always advisable to sort the Potatoes into eating and seed size before storing, and place them into different clamps, as it is easier and cheaper to do this as they are picked up from the land than it is later on. Another point is to so arrange the varieties that those which will

keep longest will come last for use. Varieties like Windsor Castle, Cosmopolitan, or others of that class will be first-class until the new year comes in, or later, followed by Magnum Bonum and Bruce, the latter being, in my opinion, the finest and best flavoured late Potato grown, and I always place it so that it will come in for use or sale when all the other varieties are over. Many gardeners and others at this season will have plenty of hedge prunings, Briers and long Grass from banks, &c. Instead of burning this as rubbish, I would suggest carting it to the Potato clamps, and on the approach of sharp weather, covering the clamps with it. It is astonishing how much frost this covering will effectually exclude, not only from Potatoes, but also from Mangold or Turnip heaps.

W. G. C.

**The protracted drought.**—It is many years since vegetable crops suffered so much from want of moisture in autumn as this season. Save one downfall of about an hour's duration, no rain has fallen in this district for many weeks; consequently all green crops are suffering much and Turnips in the open fields are much distressed. Brussels Sprouts present quite a blue appearance, having drawn every morsel of moisture from the ground. Of course, later planted quarters can still be watered artificially, but with forward plots which have met in the rows this is impossible, even if labour could be spared. Winter Spinach having its roots near the surface is feeling the effects of the drought perhaps more than anything, and I never remember having to water this crop in September before. Besides watering Coleworts, I have had to use soot freely over the foliage to disperse the colonies of insects which lack of atmospheric moisture has produced. If rain does not fall soon and in liberal quantities, the quality of winter vegetables in this district will be much affected.—J. C., Newark.

**Lifting Potatoes.**—The work of lifting and storing Potatoes that have grown to their full size is often unduly postponed, other matters requiring attention; consequently autumn rains descend, and tubers, which while the soil was dry appeared free from disease, are found to be badly affected. In East Anglia early lifting of ripened tubers is as a rule practised, even though cleaning and general routine work have to be for the time neglected, the autumn rains in that part often being heavy and continuous. Not only is disease encouraged by a sudden transition of the tubers from drought to wetness, but a second growth also by which much of the nourishing properties of the Potato are drawn out. My contention is that the malady may exist in its embryo state and yet not develop to any appreciable extent unless fostered by some excessive change either in the state of the atmosphere or the soil.—J. C.

**Mushroom culture in America.**—Mr. W. H. P. Barley, of Detroit, is one of the most energetic Mushroom growers in the country, and he makes it pay. He assures us that he can make money, growing Mushrooms at a shilling a pound. Not only has he a large establishment a few miles from Detroit, but a year ago he started another on Long Island. His Long Island houses are 50 feet long, 12 feet wide, 7 feet high, with tiers of beds, one above the other. His Detroit houses are sunk 4 feet under ground level. Manure in New York costs more than it does at Detroit and other large cities, where the gardener buys it direct from the stable and hauls it home himself. In the east, buildings cost far more than in the west; the price of timber in New York is much higher than in Michigan. His Detroit houses are built of Pine, but his Long Island ones are of Hemlock. Mr. Barley is the nephew of the late Mr. Poeock, of Mortlake, one of the best market gardeners of London. While Mr. Barley is building this new set of Mushroom houses on Long Island one of his sisters does the Detroit business. And he has another with him who

knows more about growing Mushrooms than any other woman we have ever met.—*Gardening.*

## DEEP CULTIVATION.

THE present year has again plainly proved the inestimable value of deep and thorough cultivation, for where shallow digging has been practised the major portion of the kitchen garden crops has been a comparative failure. Owing to the very dry and hot weather, many crops have been of shorter duration than in more favourable seasons, even in the best managed and skilfully worked gardens. The Pea crop especially has been giving strong testimony of the benefits arising from deep cultivation, for though the straw has been somewhat shorter than usual, the crop, size of pod and general excellence in quality have been well maintained. Cauliflowers on deeply-worked soil have been all that could be desired and are still highly satisfactory, but on quarters that have been dug only one spit deep the result has been very bad, scarcely a decent head being fit to cut, and probably, owing to the stunted condition of the plants, caterpillars abounded to such a degree that the foliage was completely riddled, while the same variety sown at the same date was entirely free on deeply dug land. Onions, again, point out still more forcibly the wisdom and, I think I may safely say, the economy of deep cultivation. In the one case, large solid bulbs that will average 1 lb. each have been produced, and in the other small, badly-grown produce that is scarcely good enough for pickling. On the latter mildew appeared suddenly towards the end of July. This was stopped by spraying thoroughly with half an ounce of sulphide of potassium to each gallon of warm water. Both runner and dwarf Beans have been extremely productive on deeply-cultivated land, and other similar instances could be mentioned as to the great advantage of the system, showing that the extra labour and expense incurred are more than repaid.

The time for, and how, to double-dig or trench require more judgment and care than many would imagine, as soils and their working are so different. As a case in point I may mention that in a garden not far from here the soil is of a very strong tenacious character, and if this is trenched into ridges in the autumn or winter, it is practically unworkable in the spring, as it seems to set almost like bricks when thus exposed to the wet and changeable weather of winter, and the gardener has repeatedly assured me that after many trials he finds it much the best policy to do all trenching or digging only a week or two before the land is required for cropping. On other strong soils it would be almost impossible to get in early crops if the trenching was not done in the autumn or winter, working in at the same time strawy manure to act mechanically on the soil, rendering it more porous and friable. Where a mistake is sometimes made is in bringing the bottom spit of clayey soil to the surface, instead of digging or turning it over in the bottom of the trench, at the same time incorporating manure, vegetable refuse, or other waste material to assist the drainage, and also enrich the soil. If a portion of the garden is thus treated annually, in a few years the soil and subsoil will be vastly improved in character, and naturally the crops will be of a higher order of merit. On lighter soils I advocate bringing the bottom spit of the trench to the top and putting the top in the bottom, unless the former is of a most inferior nature; in that case it would be a mistake to bring it to the surface. A good test of the fertility of this lower soil can be seen by noting how Lettuce and other crops answer when grown

on the ridges between Celery trenches. If these crops are a decided success, then it is plainly indicated that the bottom soil is well supplied with plant food, and that it will pay to bring it nearer the surface. I also believe many insect foes are destroyed by deep cultivation: the weather may possibly kill many, but I think birds effectually dispose of large quantities by searching over the newly-dug quarters in search of food. Another advantage of deep culture, according to my experience, is the absence of clubbing in the Cabbage tribe; neither on heavy nor light soil has this scourge put in an appearance with me, though I have been obliged on many occasions to put the same kind of crop on the quarters two or three times consecutively. In fact, the value of deeply-worked soil for all crops in either the vegetable or fruit garden is immense, and the labour necessary to perform the work ought not to be grudged.

W. G. C.

## CHRYSANTHEMUMS.

### PROSPECTS OF THE SEASON.

IN the matter of suitable weather growers will have had little to complain of, and the exceptional amount of sunshine has had a satisfactory effect upon the growth of the popular autumn flower. Everywhere one may see bronzed foliage and firm, well-ripened wood which is certain to produce a crop of excellent blooms. The flowering period does not appear to be earlier than usual. It is reasonable to suppose that the phenomenal weather of September would have brought on the blossoms with a rush. Such, however, is not the case, and I feel certain that the cooler atmosphere of an ordinary autumn is more conducive to the buds swelling quickly than is unusual warmth. It is the nature of the Chrysanthemum to open its flowers without the aid of sunshine. Where the plants have had proper attention splendid results will, as already said, follow such a season, which has enabled growers who produce large blooms to be less early in selecting buds. The exhibitions should, therefore, bring flowers of high colour, if somewhat smaller, than in an ordinary year.

If the general character of the Chrysanthemum growth is so satisfactory, I hear of troubles with insect pests from many sources. Mildew is much in evidence, also aphides, but the most harmful foe is thrips. These tiny insects are so abundant in some quarters, that the flower-buds refuse to open at all. I have often noted the work of thrips about the month of August in attacking swelling buds, and make a practice of dusting a little tobacco powder on them before any harm is done. But the pest is so tiny, that it goes on with its destruction unobserved until it is too late to save the blossoms. Fumigating the plants when under glass is the best means of getting rid of the pest now. Last season there was a general outcry about a disease which ruined plants of the fine yellow Japanese Golden Wedding. Most persons discarded the variety at once. I did not like to do that, however, and this year on my few plants of the variety there is no sign of anything wrong. The hot summer may have helped me, but I shall certainly again grow what seems to me to be the finest yellow Chrysanthemum yet introduced. There is no lack of promising novelties this year, mostly of the Japanese type of flower. This class, however, is easily first favourite, and the introduction of which has done more than anything else to popularise the Chrysanthemum. The diversity of form and

richness of colouring are marvellous; they are mostly of easy culture, too. Size, even to coarseness, has perhaps been too highly prized, but many think the maximum has been reached; the rage for enlarged show boards has ceased, and I fancy the popular taste will go for less bulky specimens. Grace and beauty of outline are often lost when the blossoms measure more than 5 inches or 6 inches in diameter. The light yellow Duchess of York should be abundant and fine. Pallanza, a deep golden yellow flower, seems likely to uphold the promise of its first blooms of last year. Mrs. C. E. Shea and Miss Rita Schroeter have excellent growth; the flowers of these two when first seen were remarkable for richness of colour and fine form. The sensational American sort, Philadelphia, is promising, although not over-strong in growth. Complaints reach me, too, that the opening buds are coloured. The idea is that the grand blooms which were sent last autumn from America were somewhat blanched by long travel, and hence the peculiarly rich ivory-white tint. We shall not, however, have long to wait before it can be proven whether the variety be a great gain among Chrysanthemums or not. I hope Directeur Tisserand will be seen in good form. This variety appeared to me the best from that noted raiser, M. Calvat. M. Chénon de Léché was also fine and of a new colour. M. Harman-Payne was also magnificent. This variety, however, is as yet very scarce, and we may not see it good until another year. Many of M. Calvat's flowers are too coarse, but as the raiser of Mlle. Thérèse Rey and Louise alone, that amateur has done enough to keep his name in the front for years to come. It appears strange to me that many exceedingly handsome Chrysanthemums after they come into general cultivation contract some undesirable habit. Thus Mme. C. Audiguier was lately seen with the petals reflexed instead of loosely incurving, which character, combined with its lovely mauve colour, gave it especial charm. The buds of Belle Paule with most growers went blind when they should swell. Viviani Morel has a tendency to produce flower-buds during the growing season at the expense of healthy foliage; and, last of all, I hear on all sides that growers have a difficulty in obtaining crown buds of Mlle. Thérèse Rey. I have myself seen many cases of blind buds on plants of this variety both this year and last. It will be a great pity if this habit becomes so bad as to prevent us growing so beautiful a flower. In the case of Viviani Morel I came across a capital plan in one collection recently. The grower (an amateur) cut his plants down to the base in June; strong sucker-like shoots were thus induced to spring from under the surface of the soil. Subsequent growth has been extremely rapid, and the plants now present clean, well-ripened stems crowned with most satisfactory flower-buds.

The character of the season, then, has been such an one as to lead us to expect a splendid period of blossoming. Later-formed buds, being less liable to decay by damping, will enable growers to cut blooms in large numbers, and we have, therefore, plenty of signs that this will be a most satisfactory Chrysanthemum year.

H. S.

**Late-flowering Chrysanthemums.**—Such varieties as L. Canning, Peter the Great, W. H. Lincoln, Fair Maid of Guernsey, Source d'Or, and a few more distinct kinds that were planted out in the open in spring should now be lifted and transferred to pots or boxes in which they are to flower. By potting them up thus early the roots will have time to take to the new soil before the autumn frosts compel the early removal of the

plants indoors. The present dry weather will necessitate the soil being thoroughly soaked about the plants. Stand the newly-potted plants in the shade for a day or two and syringe the leaves occasionally. The first-named is perhaps the finest white-flowering variety we have for cultivating in the manner named. The old roots or stools give the best results. By topping the shoots twice, the plants are now 2 feet high, and have increased the number of their stems so much, that from thirty to fifty blooms will be had from each plant, one on a stem. By disbudding as soon as the flower-buds are large enough to handle, the blooms afterwards are much finer than when all buds that form are allowed to develop.—E. M.

### Prize Chrysanthemums in New Zealand.

—Mr. Thos. Wells, the chairman of the Cambridge Chrysanthemum Society (N. Z.) and a great enthusiast in the cultivation of the golden flower, has recently, at the request of some colonial growers, prepared a list of the best thirty-six Japanese varieties for exhibitors in that colony. If I remember aright, I gave in THE GARDEN a month or two ago the names of the selected varieties, but a much more practical test may perhaps be found in the prize stand of forty-eight cut blooms which was staged at this society's last show. The varieties were as follows, viz.: Amos Perry, Bertha Flight, Beauty of Castlehill, Bryden jun., Col. W. B. Smith, Chas. Shrimpton, Coronet, Chas. Davis, Domination, Dr. H. A. Mandaville, E. G. Hill, Exquisite, Eda Prass, G. W. Childs, Grandiflorum, Geo. R. Gauze, Harry May, H. E. Widner, Ivory, Jennie Williams, Joey Hill, Jno. Shrimpton, Jas. Lynch, King's Daughter, Lady T. Lawrence, Lucrèce, Miles A. Wheeler, Mermaid, Mlle. Thérèse Rey, Mlle. M. Hoste, Miss D. Shea, Miss A. Harts-horn, M. Jefferson, Mr. A. H. Nevo, Mr. H. Cannel, Mrs. E. D. Adams, Mrs. F. A. Spaulding, Mrs. Bruce Findlay, Niveum, Puritau, Stanstead White, Secrétaire Cassagneau, Sunflower, Truth, T. H. Brown, Viviani Morel, Waban, and White Louis Boehmer. It is wonderful how rapidly and successfully the Chrysanthemum is making headway in the colony, and also how keenly alert the colonial growers are to obtain all the newest and best varieties of European and American origin.—CHRYSANTH.

**Dwarf Chrysanthemums.**—The objection to tall Chrysanthemums at Woodham Hall, Woking, has induced the gardener, Mr. Seabrook, to adopt drastic measures in the matter of cutting down the plants, resulting in the shortest specimens I have seen. Judging, too, from the appearance of the swelling flower-buds, many of the blooms will not fall very short of the exhibition standard; they are thrown a considerable distance from the leaves in many cases, which is generally a sure indication of huge blossoms. The dwarfest plants of all are those of the yellow W. H. Lincoln, the flower-buds of which are not over a foot above the pot's rim. Wm. Seward, 18 inches high, is developing very fine buds. Avalanche is of similar height, and Mlle. Marie Hoste barely 2 feet from the pots. Mrs. C. Harman-Payne, Etoile de Lyon, Col. W. B. Smith, Edwin Molyneux, and Wm. Tricker are equally short, and Mons. W. Holmes is in full bloom about 18 inches high. Such dwarfness is somewhat out of the ordinary run for the varieties named, although it is possible to obtain short-growing sorts among more recently raised Chrysanthemums without having to follow any mode of cutting back. From Louise a magnificent blossom is obtained on plants less than 2 feet in height, and Souvenir de Petite Amie bears fine white blossoms on growths of a similar height. A. H. Fewkes, a promising yellow, is also very dwarf. Mme. Ad. Chatin, a fine white Japanese flower of incurving form, may be named as being among the shortest of growers. Later introduced kinds than the above-named are commendably dwarf in habit, and it is well to keep raisers of novelties in Chrysanthemums alive to the fact that these dwarf sorts are most appreciated generally. Mr. Seabrook's plan is to strike the cuttings at the usual time and to subsequently shift the young plants into small

pots and then into 5-inch ones. The third week in May all the plants are cut down within 3 inches or so of their base. They are then carefully watered for a time until fresh growth takes place, and are given the final shift into 8-inch and 9-inch pots at midsummer. It is evident the proper details have been carried out since. The plants one and all are exceptionally clean and healthy, the foliage being of a fine dark green hue.—H. S.

#### SHORT NOTES.—CHRYSANTHEMUMS.

**Chrysanthemum Comtesse Foucher de Cariel** is one of the best of early-flowering varieties in the open. The colour, orange-yellow with a bronzy suffusion, is very pleasing. The stocky habit of growth is most desirable for an outdoor variety, while its freedom in blooming is unsurpassed.—E. M.

**Chrysanthemum La Marquise d'Ayguévives**.—This is a well-built, deep flower of the reflexed Japanese type. The colour when opening is a nice shade of salmon-red with gold points, but, unfortunately, before the flowers are fully expanded the tints lose their brightness, thus detracting from the merits of an otherwise handsome bloom. From late buds, however, the shades are rich and the bloom large enough for any purpose.—S.

## PUBLIC GARDENS.

### GARDENING AT THE TOWER OF LONDON.

THIS historical focus-spot of old London deserves a visit, not only for the new Tower Bridge, but for many other reasons; to myself at present, however, it is the trees and flowers and vegetables within the precincts that deserve a few words. The Tower dates back from about 1078, or a few years after the Norman Conquest, and at present stands on about twenty-six acres of ground, eighteen of which, surmounted by the fatal mound known as Tower Hill, being included by the railings which surround the moat or ditch, and which is now dry and partly laid down in greensward, other portions being used as gardens to this day by some of the officials residing in the Tower.

The outer slope of bank of the old fosse on the side farthest from the river is now turfed over and planted with shady trees and gay tinted flowers, so forming a pleasant retreat for the neighbouring population, its due and proper management being guaranteed by the Metropolitan Public Garden Association. These public gardens at the Tower are, however, only an example of the many fresh green breathing-spaces now so pleasantly evident among the dust and din and bustle of one of the busiest cities in the world. London has always been a city of gardens, and its citizens still love the fresh greenness in their midst and the trees and flowers of its numerous open spaces. If you go to the basement of the museum at the Guildhall you can see the earthenware watering pots used by the city gardeners centuries ago, when the Strand ran through green gardens and open fields from Temple Bar to Westminster. Tourists flock to the great Place of St. Mark at Venice to see the pigeons, but the Londoner may see them any day in the garden of St. Paul's Cathedral, cooing and feeding on the cool greensward beneath Wren's noble masterpiece, in the nooks and crannies of which they breed. The Drapers' Gardens, with their Water Lilies and Mulberry trees, and those of the old Token House are things of the past; so, too, are the noble old gardens behind Northumberland House, with their Plane trees and Hawthorns, but for one garden swept away in the London of yesterday we have double the area in open

spaces to-day. We have fresh and well-kept gardens along the Embankment, and scores of old graveyards are now fresh and green and thrown open to the denizens of the city lanes. There are all our noble squares from Kensington to King's Cross, and our London parks are wide and free, and the fountains yet sparkle in Temple Court and in the leafy cloisters at Westminster.

The open space around the Tower is peculiarly fresh and airy owing to its closeness to the broad and breezy river, and the trees and bountiful garden produce afford a good index of the freshness and purity of the atmosphere in its vicinity. In some parts the moat is turfed over, and forms a drill and camping-out ground for soldiers, other portions being devoted to vegetable culture, as I have said, with the best results. These little kitchen gardens are sheltered by the sloping walls, in places covered with Fig trees and scrambling Grape Vines, or with Ivy and Virginian Creepers, amongst which here and there gay window boxes full of flowers peep out very prettily. The tourist and sightseer wander listlessly up Tower Hill, through the jewel room and armoury, and pause again beneath the Plane trees on the little plot that has been red dyed with the life's blood of English queens. Then they go up into the prison chamber in the Beauchamp Tower, in the walls of which are "stones that speak" to us across the centuries, carved by fingers now in dust. Again you look at the paved spot under the Planes. Above stand the tall cupolas of the White Tower or Keep towering up against a fleecy sky, while down below in the old moat the gardens of herbs and blossoms lie basking in the sunshine of August, that is gilding the great disked Sunflowers of Peru, and adding a wine-red glow to the Virginian Vine, as it dangles in festoons from the grey stone walls. Gone are the days of ill-omened entrance by water through the wide-arched "Traitor's Gate," and instead we find trim gardens in its oldest water way. Each plot is sub-divided into brick-margined, rectangular beds for Mint and Thyme, Marjoram and Sage. Here are Leeks and Celery, and there Onions or Kale. Vegetable Marrows, on their rambling runners or vines, shine like golden orbs in the sunshine beside the ruddy-leaved Beet and feathery-leaved Carrots, while there are rows of Parsley as fresh and as crisp as are the daintiest tropical Ferns.

Cabbage and Parsnips, Rhubarb and Lovage, Broccoli, Cauliflowers, and Peas and Beans are here luxuriant in perhaps the self-same river mud, or rich soil, over which floated the youth and beauty of centuries ago. But you ought to go and see all this for yourself. Go early and see the Morning Glory in all its pride of royal blue, see the gold sheen of the Nasturtiums and Sunflowers, and here in the very heart of a great city you can inhale the fragrance of Stocks and Petunias and of Mignonette, Lavender and Golden Balm. That there has always been at least one garden within the precincts of the Tower goes without saying, for it is a mere matter of history that Raleigh, Thomas, the fourth Duke of Norfolk, and other noble prisoners were confined or "lodged," to put it euphemistically as of old, in the Garden Tower. The old gardens were adjacent to the Bloody Tower behind the western parapet, hence no doubt the ancient name of Garden Tower for this gateway. At the present time and for many years ago the site of the gardens has been partly built upon and partly converted into parade grounds, but visitors still may remember with interest that it was the place from which Sir Walter Raleigh looked down and conversed

with passers-by in the outer world of freedom as they came and went by Thames' glittering side. In one old history or chronicle of the place we are told that the garden of the Tower was "fenced with lathes" and used by the keeper or lieutenant for the "growing of herbes." Even to-day half an hour in the prison chamber of the Beauchamp Tower is enough, and on hot autumn days one is glad to descend and breathe the fresh outer air. What it must have been in bygone times when doors were closely shut is past belief. How welcome any little incident or distraction to those weary ones who carved their devices and mottoes on the stones around them. How welcome the advent of the jailor's pretty daughter as she mounted the narrow stair with her little basket of nosegays and sweet herb posies, culled perhaps from the aforesaid governor's garden or from her father's tiny plot beside the gate. It was on the face of the old fosse wall that Sir Walter Raleigh and Essex saw the golden Wallflowers gleaming in the sun and fresh air of springtide, while above, they, pale and immured, languished at the loopholes.

In all England to-day there is not a bit of garden ground so fraught with saddest memory as is that of the Tower. Herein grew "the cluster of white Roses and their leaves greene" worn by the beautiful Anne Boleyn on May 19, 1535, when she laid her comely head on the gruesome block with her eyes unbandaged and bedewed with tears. Essex, Raleigh, Buckingham, the Dudleys, Seymours and the Howards, kings, queens and nobles alike have contributed to make this spot one of the most time-hallowed in our history. Every nook and cranny of this old fortress are haunted by love and beauty and by manly pride in distress and loneliness. When Longschamp, Bishop of Ely, built the extensions to the older Tower, we read that he confiscated surrounding land, as Geoffrey of Essex had previously done when he wanted to make a vineyard, and in another place we find it stated that the slopes of East Smithfield nearest the Tower were known as "the gardens" until the time of Queen Elizabeth. In those days the Tower of London was a flowery place redolent with Lavender, Rosemary, Lad's Love and Thyme, but it is even more interesting to us to-day as a lion taking its rest with the Fig tree and the Vine luxuriant on its outer walls.

F. W. BURBIDGE.

### DUTHIE PARK, ABERDEEN.

This is the most important of the Aberdeen parks. It is unfortunately at some distance from the city itself, but is prettily situated, the ground sloping gradually to the side of the river Dee, thus affording better scope for good gardening than if on a level. Mid-September is not the best season to visit gardens or parks, especially after heavy rains such as have occurred of late. We made note, however, of several interesting features, and one was the good use made of the more compact annuals for edging. They gave splendid bits of colour to shrubberies, in which, as in the English parks, one saw much the same muddled-up arrangement—Laurels thrusting themselves against flowering things, as the beautiful *Spiraea arifolia*, which is very fine here.

Amongst the marginal plants we noticed *Gazania splendens*, *Silene*, *Papaver Rheas*, the Field Poppy in variety (also called Shirley Poppies), the rich brown and crimson *Linaria reticulata aurea purpurea*, annual *Chrysanthemums*, *Coreopsis*, *Godetias* (white and rose), *Platystemon californicum*, *Nemophila*, one variety of the Corn Marigold, *Chrysanthemum segetum grandiflorum*, and the lovely *Clarkia integrifolia alba*, which is one of the most beautiful of all white-flowered

annuals, especially as used in this park. *Eucharidium grandiflorum* and *Gaillardias* were flowering gaily. At the main entrance to the park are several beds of *Roses*, each variety massed together and freely planted with *Gladiolus brecheyleucis*. This gives a welcome glow of scarlet colouring. The principal *Rose* is *Gloire de Dijon*, which does better in Scotland even than in the south, the cottages and larger houses often being covered with the fragrant flowers. Amongst other *Roses* in bloom at the time of our visit was *La France*, but the time of the majority of *Roses* was over. We saw no Tea-scented varieties, such as charm one in southern gardens.

Against the bridge near the lake we noticed two of the finest banks of *Cotoneaster microphylla* we have seen, a dense mass of growth, enlivened with crimson berries. There is no water gardening. The stone edging to the water is as bare as a gravel path, but this is no worse than in London and other English parks.

The rockwork here is far better than one often sees in the south. There are more plants than stones, which are hidden with the growth of masses of hardy Ferns, *Megaseas*, and other things.

Amongst other features, very fine were the beds of single *Begonias*, the flowers exceptionally large and rich in colour, and held well up above the dense compact leafage. Two beds of a splendid scarlet variety against dark blue *Lobelia* were remarkably rich. Near to the bold *Begonia* beds by the Dee side were those of *China Asters* in full bloom, but heavy rains dash these about, whilst the *Begonias* seem unharmed by dripping skies. *Dahlias* of many kinds, early *Chrysanthemums*, *Hollyhocks*, and *Sweet Peas*, which are more popular even than in the south, gave bright breaks of colour to the masses of shrubs, some, the hardy *Azaleas* in particular, already assuming the tints of autumn.

#### VICTORIA PARK.

This is a smaller open space than Duthie Park and placed more in the city, where of course it is more appreciated. It is laid out in a pleasing way. There is an absence of meaningless walks, which split up and spoil Grass swards. A good attempt is made at getting bold masses of various plants, but sometimes the result is not always happy, especially in the confused jumble near the fountain. We were pleased to see good use made of the *Snapdragon* (*Antirrhinum*), two beds being planted with well-coloured flowers, and the white herbaceous *Phlox* was also very handsome. This is a splendid hardy plant for a good group, and flowers, when by a proper selection of things the garden can be gay as in the summer months. We should like to see the white and other decidedly coloured varieties planted well to get rich effects. We were surprised not to see such splendid autumn flowers as the *Tiger Lily* and *L. lanceifolium* (*L. speciosum*) more freely planted. They are so free in growth and bloom, that it would be worth while getting masses of them to colour the garden in September.

**Public park for Bath.**—At a meeting of the Bath City Council lately the Mayor announced the gift of *Henrietta Park* to the city from Captain Forester, who inherited the Bathwick Estate from the late Duke of Cleveland. The park, which was formerly a private one belonging to the estate, is situated in the centre of the city, and will probably be laid out by the Council as a public pleasure ground. A resolution was passed gratefully acknowledging the gift.

**Connaught Park, Dover,** is very well worth visiting. The borders of *Petunias* are finer than I ever saw before. The soil evidently suits them, and there is a very great variety of colour. The upper border has annuals and herbaceous plants mixed, and is very gay. There is a long pond full of gold and silver fish, some *Water Lilies* and other plants. It is in a very warm situation. *Aponogeton distachyon* ought to thrive splendidly.

*M. Latour-Mariac's Water Lilies* ought to be in the pond.—GEORGE F. WILSON.

**Open spaces.**—At the monthly meeting of the Metropolitan Public Gardens Association, 83, Lancaster Gate, lately, Lord Teynham, vice-chairman, presiding, it was announced that an open space in Quadrant Street, Canning Town, had been laid out and opened by the association; that seats had been placed in North End Road, Fulham, Goldhawk Road, Hammersmith, recreation grounds in Twickenham and East Ham, Dulwich High Street, and a space by the Old Street Tabernacle; that a letter had been written to the council of the United Synagogue respecting the condition of some of the Jewish disused burial grounds, and that the West Ham Corporation had agreed to plant additional trees in Freeman's Road. Communications were read respecting the proposed laying out of Marian Square, and the churchyards of St. James's, Piccadilly, St. James's, Pentonville, St. Matthew's, Bethnal Green, St. John's, Westminster, and Christ Church, Blackfriars Road; and it was agreed to continue negotiations respecting some lammas land at Tottenham, the Copperas, Bromley, the vacant site in East Street, Walworth, and other spaces; and to secure a site for a recreation ground in Deptford. A grant of £10 was made for a gymnasium in Southwark, and for six seats for Bloomfield Road, Paddington. Amongst the matters considered at the meeting were the preservation of Ham Common and Chureyard, Bottom Wood, Highgate; the improvement of a small plot of land in Plumstead, the opening of Albion Square, and the burial grounds in Long Lane, Southwark.

## SOCIETIES AND EXHIBITIONS.

### NATIONAL CHRYSANTHEMUM SOCIETY.

OCTOBER 8, 9, 10.

The October show of this society, which has now become a more important fixture than heretofore, was held on Tuesday and the two following days. It was the prettiest show, we think, ever held at this season of the year in the Royal Aquarium. Greater taste was shown in the arrangements and the competition was keen in every class. One can scarcely tell at a glance what month we are in if we judge by *Chrysanthemum* blooms. Those shown on this occasion were quite as large as those seen in November. This is not an advantage, but it shows how busy raisers have been in acquiring fullness and size in their interesting productions.

The great class was for twenty-four blooms of Japanese varieties, and the prize was won by Mr. W. Wells, Earlswood Nurseries, Redhill. He had a splendid stand of flowers, conspicuous amongst the varieties being *Eda Prass*, *Louise*, *Thomas Wilkins*, *Boule d'Or*, *President Borel*, *Mme. E. Rey*, *Rose Wynne*, a variety which was very fine throughout the exhibition, and *Frank Wells*, a flower of a very light and pretty lemon shade. The second prize was awarded to Mr. C. Cox, and the third to Mr. R. Jones, gardener to Mr. C. A. Smith, Barford Hall, Warwick. In the class for twelve Japanese flowers, Mr. Jones won with a very fresh and even collection of blooms, in which we noticed fine examples of *Rose Wynne*, *Mrs. E. G. Hill*, *Mlle. Thérèse Rey*, *Commandant Blusset* and *Mons. Charles Molin*. Mr. James Brookes, gardener to Mr. W. J. Newman, Whetstone Hall, Totteridge, was second, and Mr. W. Collins, Ponsbourne Park Gardens, Hertford, third. Twelve very creditable blooms of Japanese varieties came from Mr. J. Knapp, gardener to Mr. F. W. Amnden, Chichester Road, Croydon, the blooms of the varieties *W. G. Newitt*, *W. H. Lincoln* and *Mlle. Thérèse Rey* being very fine. The second prize was awarded to Mr. T. L. Turk, gardener to Mr. Boney, Southwood House, Highgate. The best six blooms in the Japanese class were from Mr. J. Knapps, the second prize being

awarded to Mr. A. W. Southard, gardener to Mr. H. B. Kenyon, Sutton.

The incurved flowers were naturally not so fine as those of the Japanese class. A very satisfactory six, however, were those from Mr. W. Collins, which secured the premier award. Especially noteworthy were the varieties *M. Bahuant*, *Prince Alfred*, *Lord Wolseley*, *Mme. Darrier*, and *Refulgens*. The second prize went to Mr. R. Filkins, gardener to Miss Alexander, Oakbank, Chislehurst. Mr. Turk, we may mention, also had good incurved blooms, winning in the class for six.

We must not omit to mention that the twelve Japanese flowers from Mr. H. Love, Sandown, Isle of Wight, were very noteworthy. *Phœbus* was superb in colour and form. The second prize in this class went to Mr. W. Amies, South Ashford, Kent.

*Pompons* were exhibited extremely well. The twelve bunches that came from Mr. Chas. Brown, gardener to Mr. R. Henty, Langley House, Abbots Langley, Herts, were amongst the finest we have seen at this season of the year. That exquisite kind *Mlle. Elise Dordan* was in perfection throughout the exhibition, and a variety named *Flora*, rich yellow, was also very beautiful. *Miss Debenham*, *St. Peter's*, *St. Albans*, was second. In the class for six, the last-mentioned exhibitor was to the front. We noticed in this stand a very beautiful kind named *Ryceroft Glory*, of a rich yellow shade, and one of the best of recent additions to this class. Mr. Turk and Mr. Chas. Brown were second and third respectively.

The groups formed a very handsome feature. Mr. H. J. Jones, Rycroft Nursery, Hither Green, Lewisham, was an easy first. His flowers were not only extremely fine and of recent varieties, but staged with great taste, not jumbled up and massed together, as the prevailing fashion now is. In such a group as Mr. Jones' we get light and shade—an artistic arrangement. The second award was made in favour of Mr. W. Howe, gardener to Mr. H. Tate, Park Hill, Streatham Common.

Table decorations were a conspicuous feature, and many of them remarkably pleasing by their distinctness and elegance. The largest class was for the three best filled epergnes, Mr. J. R. Chard, Stoke Newington, as usual, securing the first prize. The *Chrysanthemum* flowers were lightly arranged with appropriate foliage. A very close second was Mr. D. B. Crane, Woodview Terrace, Archway Road, Highgate, N., whose choice of *Croton* leaves, berries and *Chrysanthemum* flowers made a happy piece of seasonable colouring. Mr. Chard was first also for a table of bouquets and wreaths. For two vases of *Chrysanthemums*, Mr. T. Tallett, gardener to Mr. G. Alexander, Warley Lodge, Brentwood, Essex, was first with a bold and pleasing arrangement, whilst Mr. Jas. Brookes was second. Mr. D. M. Hayler, gardener to Mr. W. Hannaford, Tenterden Hall, Hendon, won the premier award for a single vase, Mr. D. B. Crane coming second.

#### MISCELLANEOUS EXHIBITS.

Miscellaneous groups, as usual, formed a very large feature of the exhibition. A tremendous display of the finest varieties of *Dahlia* was made by Mr. T. S. Ware, Hale Farm Nurseries, Tottenham. The huge fountain-like arrangement in the Aquarium was a mass of bloom, arranged in distinct blotches of colour. As the varieties have been frequently mentioned this season we refrain from doing so on the present occasion (silver-gilt medal). A similar award went to Messrs. J. Cheal and Sons, Crawley, who filled with flowers and fruit the corresponding fountain at the other end of the building. *Dahlias* were a fine feature, but the fruit was superb. We must mention Cox's *Pomona*, *Mère de Ménage*, *The Queen*, *Jubilee*, the finest fruits we have seen of this Apple, *Bramley's Seedling*, *Peasgood's Nonsuch*, *Gloria Mundi*, *Bismarck*, *Emperor Alexander*, *Cox's Orange Pippin*, *Collini* (of splendid colour), *Lane's Prince Albert*, *King of the Pippins* (very large), *Ribston Pippin* and *Blenheim Orange*. The same award was also made to the fruit from Messrs. J.

Laing and Sons, Forest Hill. It was a splendid collection, the Apples well coloured, such varieties as Emperor Alexander, Flower of Kent, Stirling Castle, Cellini, Sandringham, Cox's Pomona, Gold Medal, Peasgood's Nonsuch, Bismarck, Lord Derby, Gascoigne's Scarlet and Alfriston being remarkable for size and colour. Mr. H. Berwick, Sidmouth Nursery, Sidmouth, Devon, also showed splendid fruit, the collection large and well set up (silver-gilt medal). Messrs. Spooner and Son, Hounslow Nurseries, Middlesex, received a silver medal for a very fine and interesting collection. Amongst other exhibits in fruit and vegetables we noticed a large display of the well known Onions of Mr. H. Deverill, Banbury, Oxon, to which a silver-gilt medal was awarded. Messrs. Dobbie and Co., Rothesay, N.B., had vegetables, amongst them Dobbie's Champion Leek; also flowers of the single Cactus Dahlias (silver medal). Fine fruits of Apple Royal Jubilee were shown by Mr. T. Fanning, Bath Road, Hounslow.

Messrs. Cannell and Sons, Swanley, Kent, showed a splendid group of Cannas, conspicuous among the varieties being that called Queen Charlotte, the flowers red on a yellow ground; also the interesting Margaret Carnations, besides Cockscombs in a delightful and unusual series of colours, pink and many tender shades, and a glorious mass of the finest Cactus Dahlias. A silver-gilt medal was awarded. Mr. H. J. Jones had a like award for his superb collection of new Chrysanthemums, beautifully arranged with Ferns and Asparagus plumosus. A white, full, finely-formed Chrysanthemum named Emily Spilsbury is worthy of note; it is a distinct gain. The varieties of zonal Pelargoniums are numerous and fine, especially Star of Ryecroft (white, carmine-salmon centre), Alice M. Love (pink), and Etoile de Lyon, but we shall have occasion to refer to these and many other new kinds again. Messrs. Cutbush and Son, Highgate, had a large display of hardy flowers and a promising new Tomato named Polegate Seedling (silver medal). Mr. Godfrey, Exmouth, Devon, had cut flowers of Carnation Reginald Godfrey (pink) and Mary Godfrey (white); also a large collection of cut Chrysanthemums, amongst them many promising seedlings. Mr. H. Briscoe-Ironside, Cedar Lodge, Burgess Hill, Sussex, had a silver medal for Chrysanthemums. Mr. Higgs, The Gardens, Fetcham Park, Leatherhead, showed plants in full bloom of Saintpaulia ionantha from January-sown seed. Mr. W. Wells showed many varieties of Chrysanthemums (silver medal); also Mr. H. Shoemith, Claremont Nursery, Woking, that fine Japanese variety Phœbus being especially worthy of mention. A silver medal went to Messrs. J. Veitch and Sons, Chelsea, for a group of Chrysanthemums; also one to Mr. T. S. Ware. Mr. G. Reid, The Nurseries, Beckenham Hill, Kent, had an interesting group of Dahlias and Cannas.

The floral committee of this society held a meeting on Tuesday last at the Royal Aquarium, the chair being taken by Mr. T. Bevan. The exhibits were numerous and of a high average of excellence. First-class certificates were given to—

**CHRYSANTHEMUM PRESIDENT ARMAND.**—A large incurved Japanese, with long, grooved, pointed florets. Colour inside carmine-chestnut, reverse brownish yellow. Staged by Mr. J. French, gardener to Mrs. Berkeley, Ambleside, Wimbleton.

**CHRYSANTHEMUM PHÆBUS.**—A Japanese; very full and deep, florets of medium width. Colour rich golden yellow. From Mr. H. Shoemith.

**CHRYSANTHEMUM MONS. C. MOLIN.**—A large spreading Japanese, with broad flat florets. Colour a rich shade of yellow with a tinge of carmine on the outer florets. Shown by Mr. Godfrey.

**CHRYSANTHEMUM BOULE D'OR.**—A grand novelty in the incurved Japanese section and not to be confounded with the variety already bearing that name. It is a solid, massive flower, with broad, grooved florets, and the colour is soft amber or

golden buff. This came from Mr. Wells, of Earlewood.

**CHRYSANTHEMUM MONS. AUGUSTE LACVIVIER.**—An effective variety of the same type. Broad incurving florets of a rich crimson-cerise, reverse golden rose, which two colours form a striking contrast as the bloom is in course of expanding. Sent by Mr. Jones, of Lewisham.

**CHRYSANTHEMUM LADY RANDOLPH.**—A compact, globular Japanese. Colour purple-amaranth, reverse silvery.

**CHRYSANTHEMUM MME. MARIE MASSE.**—A pretty, early-flowering decorative Japanese. Colour rosy mauve, with golden centre. Shown by Mr. D. B. Crane.

**CHRYSANTHEMUM LADY ESTHER SMITH.**—Japanese incurved. Very long, grooved curly florets; a solid looking flower. Colour white. From Mr. Owen, of Maidenhead.

**CHRYSANTHEMUM YELLOW GEM.**—A pretty little pompon, globular in form, the tips lacinated, colour pale yellow. Also from Mr. Owen.

A new white Japanese called Emily Spilsbury was shown and was awarded a vote of thanks. Mr. Briscoe-Ironside, sent a new rotary exhibition stand for cut blooms, a valuable suggestion for those who object to the orthodox showboard. He was awarded a high commendation and a small silver medal. An American Japanese A. H. Fawkes, a yellow incurving variety, was commended. There were some other very fine novelties staged, but we can say nothing concerning their merits on account of the eagerness displayed by the exhibitors in removing them immediately the committee rose.

**Royal Horticultural Society.**—The next fruit and floral meeting of the Royal Horticultural Society will be held on Tuesday, October 15, in the Drill Hall, James Street, Victoria Street, Westminster. The committees will meet as usual at 12 o'clock, and at 3 p.m. a lecture on "Nut Culture in England" will be given by Mr. J. Omer Cooper.

**United Horticultural and Benefit Provident Society.**—We are asked to state that Mr. James H. Veitch will preside at the annual dinner of this deserving institution, which will be held at six p.m. on Thursday, October 17, at the Cannon Street Hotel. Tickets may be had from Mr. W. Collins, Secretary, 9, Martindale Road, Balham, S.W.

## NOTES OF THE WEEK.

**Solanum jasminoides**, one of the sweetest climbing plants, well merits a place under glass where there is abundant space for its extension. There is a fine specimen of it in the conservatory at Alnwick Castle, growths from 12 feet to 20 feet long bearing numbers of clusters of white flowers. These shoots are cut clean back to the main branches every year.

**Collomia grandiflora.**—In a recent number of THE GARDEN this well-known species is referred to as being of perennial duration. This is undoubtedly incorrect, as it is a true annual like its brighter coloured ally, *C. coccinea*. It comes up every autumn in my garden from self-sown seeds, which it ripens in abundance, but never puts in a second appearance after flowering.—SENEX.

**Chrysanthemum Mme. Leoni Lassali** is a very fine variety that Mr. Harris grows largely in the gardens at Alnwick both for cutting and for its fine effect in masses or groups. The plants are 2 feet or a little more high, but they flower from bottom to top with great profusion, showing much more lateral bloom than those of the Mme. Desgrange type. The flowers also are of fine size, reflexed form and white, shading to yellow in the centre.

**A double-spathed Arum Lily.**—By same post I forward to you a bloom of a double-spathed Arum Lily. It was grown from a well-matured

tuber, dried off and repotted in good compost early in August. I grow a large quantity, but have not before found anything like it.—C. BLOODWORTH, *Nettingham*.

\* \* Not at all uncommon; we have had many such.—ED.

A fine **Bougainvillea glabra** is the centre of attraction among many beautiful conservatory climbers in the conservatory at Alnwick Castle. Confined root space and unlimited head room would appear to be most conducive to profuse blooming, judging from the conditions under which this plant is growing. This is pruned hard back each spring, and the many long shoots this season are now terminated by wreaths of the characteristic and highly coloured bracts.

**Rudbeckia occidentalis.**—The plant referred to under this in your last issue as being now in flower at Kew is certainly some other species, as that is described by Gray in his "Synoptical Flora of N. America" as having no ray florets, being placed in the section *acosmia*. Can it be the *R. californica*, which is a showy species, though less so perhaps than the best forms of *R. laciniata*, which are found in gardens under several aliases?—W. THOMPSON, *Ipswich*.

**Streptocarpus from Chelsea.**—We have the pleasure to send herewith for your inspection a few flowers of *Streptocarpus*, showing the results of our latest crossings. The plants have been grown in a pit and the flowers are now very much smaller than they have been, but they are fairly representative of the colours we have obtained.—JAMES VEITCH & SONS.

\* \* A beautiful gathering, showing the great improvements that have been made in the colours of these within the past few years.—ED.

**Abutilons in large conservatories.**—One rarely sees *Abutilons* so beautiful as they are in the conservatory at Alnwick, where they have an abundance of room to grow, and in their present delightful profusion of bloom suggest the wisdom of planting them more freely in spacious structures. A plant of the yellow-flowered variety has a run of 5 feet on the back wall and thrusts its many-flowered branches far out into the house. Another fine specimen of *Boule de Neige* hides a pillar and makes a thick column of leafage set off by hundreds of snow-white blooms.

**Carnation Primrose Day.**—Some fine flowers of this yellow Carnation have been sent us by Mr. H. B. May, of Dyson's Lane Nurseries, Edmonton. It has all the essential qualities of a first-rate Carnation, the flower being of fine size, clear colour, and having a long pod that will not split. It has besides a delicate scent, and in this respect is an advance upon other yellow selfs. It is an open-air kind, and worthy of a trial beside *Germania*, to which it may prove a fit companion. An award of merit was granted to it at the Drill Hall on June 12 of last year.

**Begonia Captain Holford.**—When looking through the extensive and beautiful grounds at Westonbirt the other day I saw a charming bed of this new *Begonia*. I never saw a finer or more suitable plant for beds. The habit and colour are perfect, while the freedom of blooming is remarkable. The colour of the flower is a bright coral-red both inside and outside the petals. It has somewhat the style of growth of *Emperor*, only much dwarfer. It is not yet in commerce, but I feel sure if it is ever placed on the market it will quickly become one of the leading *Begonias* for the flower garden.—J. A.

**Dendrobium Phalænopsis Schrederia.**—We are reminded of the exceeding beauty and the great diversity of colours in this *Orchid* by a gathering from Mr. J. Cypher, of Cheltenham. The colours range from purple and purplish rose to the delicately beautiful lighter tints, in which the ground colour of pure white is softly suffused with rose or purple. In one case the flowers are nearly pure white. It is a free growing plant and enjoys an abundance of moisture and heat. The flowers last a long time in perfection after they have been cut, which still more adds to their

value. The good old *Dendrobium nobile* in this has a formidable rival.

**Nectarine Vineux Henri de Monicourt.**—Messrs. Transon Frères, of Orleans, send us this. It is a very interesting and quite a distinct fruit, but we are unable to judge of the flavour after such a long journey as it has undergone, though we should say it would be well worth a trial. It is a late kind, ripening at Orleans from the 1st to the 10th of October, of medium size or large, and having a smooth, shining surface. It has a dark blood colour, striped with violet; the flesh is blood-red, and we are reminded of a Beetroot. Messrs. Transon describe it as a well-flavoured and juicy fruit, the tree vigorous and fertile.

**Tubercus-rooted Begonias.**—I am sending you a few blooms of my new seedling Begonias from my own seed sown this year. They are flowering in the open, therefore have been knocked about a good deal by rain and cold. Of course they will be much larger and finer next year.—EDWARD EDWARDS, *Holmeside, Leighton Buzzard.*

\* \* A lovely series of Rose-like flowers, some colours delicately tinted like a Tea Rose, some brilliant self, others salmon-buff. All the colours are good, none of those magenta shades so unpleasant and poor in many flowers. The blooms are perfectly double, without the ugly centres that disfigure many tubercus Begonias. We hope Mr. Edwards will go on raising such beautiful things as these.—Ed.

**Two good pillar Fuchsias.**—We are glad to see an extended use is being made of Fuchsias to clothe the rafters and pillars of glass structures. They are often very beautiful at Kew, and in the Chelsea nursery one house has all its main rafters clothed with Fuchsias. In the conservatory at Alnwick they are equally beautiful as pillar plants. Two varieties not long planted here Mr. Harris thinks highly of, as they are of rapid growth and quickly attain great height or length, a most essential thing. One is Miss Rundle, which has made a leader 12 feet long this year, as well as flowered abundantly on the laterals. It has bluish-white sepals and bright red petals, and is a long, lovely flower. Olympia, almost as free growing, has flowers of a purplish rose in the petal, but with bluish calyx.

**Kniphofia pauciflora** × **Macowani.**—This interesting hybrid was raised at Kew by Mr. Dewar, and flowered soon after he went to Glasgow. It has no claim to floral beauty, and I am afraid Mr. Gumbleton would class it among the "tush" plants. When Mr. Baker drew up his description of it in 1893 the flowers were white, but several other plants of the same cross have since flowered, and they show variety, one having creamy yellow and another yellow and orange-coloured flowers. The leaves are each from 1 foot to 18 inches long, narrow, triangular, the margins scabrid; the scapes are nearly 2 feet long and the flowers form a head 3 inches long, each flower measuring three quarters of an inch. *K. pauciflora* is a slender little species of doubtful hardness, which first flowered at Kew in 1889.—W. W.

**Kniphofia Nelsoni.**—I agree with Herr Max Leichtlin's description of *K. Nelsoni* if he will allow me to add that it is the leveliest of all Kniphofias of its class. It will not compare with such gaudy giants as August Wilhelm or T. II. Ware, or even the grand old typical *K. caulescens* itself. If Kew had not received a plant of *K. Nelsoni* from Mr. Gumbleton last year I should have concluded from what he says of this species on p. 256 that he had got hold of the wrong thing. The Kew plant has now five spikes, two of which are within an inch of 4 feet in height, and two nearly 3 feet, whilst in colour the flowers are as brilliant a scarlet as those of *K. corallina*. Mr. Gumbleton's plant must be out of condition. I am certain that if he saw the Kew plant he would be willing to award a place among the good garden plants to *K. Nelsoni*.—W. W.

—With gardeners the opinions about plant beauty may differ, but certainly Mr. Gumbleton

would have a much higher opinion of the beauty of this plant if he could see the charming group in my garden here. The strongest plant has twelve scapes, the longest 54½ inches and the smallest 28½ inches high; the spikes are respectively 8 inches and 4½ inches long and 1 inch to 1½ inches thick. I fear Mr. Gumbleton has either a bad variety or the climatic or other conditions at Belgrove do not exactly suit it. The colour of my blooms is superior to that of those of *K. Macowani*, and the foliage continues to grow on in winter and does not even look faded, but fresher and of a healthy green. The long narrow spikes and the high colour give it a peculiar charm and elegance. I am quite sure it will become a favourite when better known, and I still maintain what I have stated about its beauty.—MAX LEICHTLIN, *Baden-Baden.*

**Kniphofia Woodi.**—Plants of this new species were sent to Kew last year by Mr. Medley Wood, curator of the Botanic Garden at Natal, after whom it is named. One of them was planted out in a border in a cool greenhouse, where it has lately flowered. It resembles *K. modesta* in general characters, but is stouter, and the leaves have a few distant marginal spines. The scape is 3½ feet high and the flowers are in a dense, narrow head 9 inches long, each flower being only half an inch long and of a pale cream colour. In *K. modesta*, which first flowered at Kew in 1889 and may be seen in bloom there now, the scapes are only 2 feet high and the leaves have smooth margins, otherwise the two might be called mere forms of one species. Probably *K. Woodi* will prove useful to breed from; it grows and flowers freely in a cool house. Whether it would do out of doors has not yet been proved.—W. W.

**Anemone japonica alba var. Lady Ardilaun.**—In THE GARDEN (September 14, p. 198) "J. C. B." refers to the above as being subject to discoloration of foliage. I being the raiser of this Anemone, and having grown it from its infancy up to the present, will gladly give my experience for "J. C. B.'s" information. I have grown it in various positions and have had no experience of the spots referred to save on one occasion, when I planted a bed which had been heavily dressed with fresh manure. For the first two seasons the foliage of the plants in this bed became spotted as described by "J. C. B.," the third season the plants attained a height of 5 feet, well furnished with luxuriant foliage quite free of any blemish. I attribute the cause of the discoloration the first two seasons to the rich soil in which they were planted. I have found this Anemone do admirably in fresh soil and leaf-mould thoroughly pulverised to a depth of at least 18 inches. If planted firmly and supplied with water in dry weather until the roots become established, the plants grow freely and develop their large glossy leaves, crowned with an abundance of bloom, which in time is replaced with large heads of seed. These if allowed to become ripe can be drawn out to a width of 6 inches, left intact, and laid on a seed pot or pan prepared for them, covering them lightly with sandy soil, placing a piece of glass over each pot and giving a little water as the surface becomes dry. Plants which will flower freely the following autumn will be produced.—A. CAMPBELL, *The Gardens, St. Anne's, Clontarf, Co. Dublin.*

**The weather in West Herts.**—The seventh warm week in succession and the hottest of the series. On five days the highest shade temperature exceeded 75°, and on the 26th and 27th 82° was registered. The nights were uniformly warm for the season, and the exposed thermometer on no occasion fell below 43°. Until the night preceding the 2nd inst. (when nearly a quarter of an inch fell) there had been no rain sufficient to lay the dust for nearly a month; indeed, no rain-water whatever has come through either percolation gauge for ever a week. During September there occurred only two unseasonably cold days, but a good many moderately cold nights. On three

days the maximum shade temperature was 82°, which is a higher reading than any recorded here in September during the previous ten years, and, with one exception (May 30), higher than any similar reading registered this year. At 1 foot deep the ground, taking the month as a whole, was 1½° warmer than in any September since observations were started here in 1885. Practically the whole of the total rainfall was deposited during a thunderstorm on the night of the 6th, and amounted to less than 1 inch. During the past forty years there have been only two Septembers at Berkhamsted as dry—viz., 1865 and 1890—and only one (that of 1865) with as few rainy days. There occurred only one day when no sunshine at all was recorded, and on as many as twenty-two days the sun shone brightly for over seven hours a day. As compared with the ten previous Septembers, the aggregate record exceeded the brightest of these by as much as fifty-one hours. Besides being such a very warm, dry and sunny month it proved also the calmest September of which I have here any record; in fact, the average rate of movement of the air at 30 feet above the ground was only four miles an hour. The atmosphere was, moreover, drier during the past month than in any of the preceding ten Septembers.—E. M., *Berkhamsted, Oct. 3.*

—The weather of the past week has been in every respect a contrast to that of the one preceding it, being cold, wet and sunless, with higher winds and a much more humid atmosphere. The day temperatures have, as a rule, been only about seasonable, but on two nights the exposed thermometer fell to within 5° of the freezing-point, and on two others slight frosts were indicated by it. During the week the temperature of the ground at 2 feet deep has fallen nearly 5°, and at 1 foot deep nearly 7°. At the latter depth the reading is now, however, still 4° above the average for the month. Rain has fallen on every day but one this month, and to the total depth of nearly 2½ inches, so that during the last eight days there has been as much rain as in the previous seven weeks. No rain water at all came through either percolation gauge during the nine days preceding the 4th inst., but since then an amount equivalent to about four and a half gallons through every square yard of surface has come through them. The wind blew with the force of a gale during the afternoon of the 3rd inst.—the highest record was thirty-two miles for the hour ending 3 p.m.—the direction west. This is the strongest wind experienced here since March 24. On three days no sunshine at all was recorded, and on one the sun shone for less than an hour.—E. M., *Berkhamsted.*

**Ostrowakia magnifica.**—I got two plants of this last year about 10 inches long. I put one into a 9 inch pot, the other into the open border. They both stood over last winter and grew about 9 inches high, then withered away. The roots at present appear healthy. Can any reader assign a reason for this?—J. RANKIN, *Airdrie.*

Which does mend Nature: change it rather; but  
THE ART ITSELF IS NATURE."—*Shakespeare.*

## FLOWER GARDEN.

### MICHAELMAS DAISIES.

WHAT I write in my notes about flowers is founded on my experience of them in the latitude and climate of the midland counties. It may not all be true if tested by their habit in the Isle of Wight or in Perthshire. For instance, when I write that a plant is better in Cheshire for being sheltered from cold winds, and a correspondent replies that this is quite a mistake because it grows well in the south of Hampshire without any such shelter, most readers will perceive that the two places in question are rather different. This preliminary remark is especially required in writing of Michaelmas Daisies. Taking average seasons, we should find that the Michaelmas Daisies of Surrey, of Yorkshire and of Aberdeenshire are represented by three different sets of plants, and that those which flower at Michaelmas in the first-mentioned county would never reach flowering at all in the last. Still, it is not before Michaelmas, but after it, especially where florists' Chrysanthemums will not flower out of doors, that most of us want Michaelmas Daisies; and therefore our selection of them must be suited to the climate in which we live. This year most of them have been too early, or rather too short, in their duration; they came in with a rush at the beginning of September, and after a very bright life were many of them over by Michaelmas Day. Those which come out after it will not live so fast and will last longer. One good result of the early flowering is that seeds are sure to ripen, and so improved varieties may be got. To give a list of names of the best varieties is of very little use, even if the names are correctly given. Those amateurs who will take the trouble—and it is very little trouble where there are a few square yards of ground to spare—to raise a thousand seedlings from seed of the best varieties may have something better than the best varieties, and suit them to their own taste. The plants will, if seed is sown in the open air in February or in late autumn, nearly all of them flower the next September. A mark should then be tied to fifty of the best of them, and when the leaves are brown the fifty should be promoted to a better place. This movement may be made any time that frost is out of the ground. By raising seedlings in this way I have already superseded at least half the flowers honoured with three stars by the Chiswick conference.

I must say something about colours. Ancient writers speak of a plant called tripodium, which changed its colour three times in the day, having a distinct morning, noon and evening colour. Perhaps by accident the name was attributed by our early herbalists to an Aster, but certainly Michaelmas Daisies seem to deserve that name because they vary remarkably, according to the way the light falls upon them, and the same flower will seem of a very different hue before breakfast, and at noon, and an hour before sunset, the last of the three aspects being by far the best, and as the fullest light is the most trying for them, midday is the time at which they ought to be judged. In the old *Novi-Belgii* types, mauve—a sort of pale red-purple, a colour abjured by artists—prevailed. We have

quite enough of these, but want lighter and darker and purer colours. A flood of whites has come upon us in the last three or four years. At the Chiswick conference good whites were very limited in number, but making every allowance for the whiteness which has prevailed in the versicolor section this season, owing to the sunshine and the absence of rain, we now have pure white Asters enough to satisfy us for several years. From the bright little versicolor *nanus*, rising hardly 6 inches from the soil, to forms nearly as tall and large in the flower as *punicus pulcherrimus*—8 feet high—there are so many good whites of every stature and coming in succession, that I find it hard to make a selection for naming. Blues (I mean true blue) are still a great desideratum. *Archer-Hind* is late for Michaelmas here, and after all is not bright enough to look really blue at a distance. A seedling I sent to several gardens two years ago named *Nancy* is a really conspicuous pale blue of first-rate habit, but a little too early. I have raised two or three other blues, of which I wish to see more before naming them or letting them go into public.

The varieties of *Amellus* are all of them this year too early and over before October, but out of two or three hundred seedlings which have flowered here and which vary much, I can find only three which come near real blue, and these are nearest it in a clear evening. Most of them mix red in their colouring and are deteriorated in proportion to its quantity; still a close mass of these flowers a yard or more in diameter is gorgeous. The white Aster *Amellus* from Geneva has so far disappointed me, both rays and disc being small and dingy. I hope to improve it from seed which it is making. It is hard to find names for colours, but there is a clean and pleasing colour prevalent amongst my seedlings, something between pale brown and lavender. It is rather a new colour in Asters, and so worth selecting. Many of these have a diffuse branching habit like *turbinellus*, which has a good distinct habit, but is generally too late here. As for dark purple, *arcturus*, a plant of fine habit, is the best I have; seedlings from it have all come of lighter shades. For free-flowering and elegant spreading form down to the ground, *W. J. Grant* is still unsurpassed if well grown. For pink, the dwarf Aster called at the conference *levigatus* is, as far as I know, in possession of the field. The tall varieties called rosy and red of *Novæ-Angliæ* are of a different colour from this, but all the *Novæ-Angliæ* forms are too tall; out of 100 seedlings I produced no improvement on *W. Bowman*, and the red varieties do not choose to come dwarfed. It only remains to say a few words on the cordifolius class, of which *Diana*, when well grown and allowed free room to spread and hang down its elegant waving plumes, remains the greatest favourite. It must not be in dry soil or in full sun, as it withers before flowering in such situations, but it wants moist, light soil and shelter, if not shade. It is one of those plants so often asked for which like a northern aspect. I have many seedlings from it which equal or surpass it, having even larger plumes; one or two with rays of pure white, but retaining the purple disc, are worth notice. Much more might be said about the whole class and its treatment, but I hope that by limiting these notes I am making room for others to have their say on the same subject. C. WOLLEY-DOD.

*Edge Hall, Malpas.*

***Polygonum sachalinense.***—This is now a fine feature in the garden at Fairlawn, Wimbledon Common, the residence of Sir Edwin Saunders.

A large clump on a cool shaded border has produced its delicate greenish yellow flowers in long pointed axillary racemes. A more accommodating or persistent plant it is difficult to name, and it grows and flowers with little if any trouble to the cultivator. Blooming freely at this season of the year, it makes a very ornamental late summer flowering perennial of bold and striking character.—R. D.

***Primula capitata.***—As an autumn blooming plant this lovely species is decidedly the most beautiful and certainly the most welcome by reason of its free and continuous flowering. A large group of it that has been in bloom for some time past in the rock garden at Kew shows its free-flowering character. Some of the heads are in full flower, many others just expanding their earliest blossoms, and others again in every stage of development. It is certainly a valuable species from a variety of standpoints, as, apart from its more natural season of flowering, it may be had for a great part of the year by simply regulating the raising of the seedlings. It should always be understood that it is not a good perennial—that is to say, its greatest decorative value is not forthcoming when treated as such. But if regarded more in the light of a biennial, raising three or four batches of plants every second year or two batches each year, the various stages and ages of the plants would produce an unceasing array of bloom. But if the plants are to be wintered in the open, care should be taken that they do not approach flowering at the opening of winter. By planting in various positions also much may be done with it. The group at Kew is raised somewhat, and, standing well to the view, the rich deep violet-purple of its flowers appears in striking contrast with the dense silvery meal that covers stems, leaves and flower-buds. As a garden plant it has a special value in providing so rich an array of blossoms when the major portion of the Primrose family is at rest. It is of quite easy culture if given a good depth of sandy loam and kept fairly moist in dry weather.—E. J.

### FLOWER GARDEN NOTES.

**THE BEGONIA DISEASE.**—A comparison between Mr. Tallack's remarks in a recent number, those on p. 264 and the editorial note appended to the latter would seem to indicate that some mistake has been made, and that the leaves sent to THE GARDEN office to illustrate the disease were changed, as it is not reasonable to suppose that writers like Mr. Tallack and "J. C. C.," who are apparently keen observers in flower garden matters, would not be aware of the condition of leaves attacked by thrips and attribute it to a disease of a mysterious character. Certainly the Begonia disease, as we have it here, is not caused by any insect, but is more like the fungus or black mildew that is answerable for so many failures with *Lilium candidum*, and, as stated in last week's GARDEN, I have found nothing as yet to check its progress. It would be a great boon if any grower troubled with the disease who has tried remedial measures and found them effectual would give the benefit of his experience.

**SPECIAL HARDY FLOWERS FOR CUTTING.**—With the view to carry on information for another year's requirements, I have jotted down from time to time through the past year in their respective seasons those hardy flowers that have proved most serviceable for cutting, and although tastes may and do differ to a considerable extent, it may be taken for granted that those things enumerated below are hardly likely to go out of favour, and their planting, where not already established, may be safely recommended. Daffodils are about the earliest flowers obtainable in quantity, and may be planted at once in the varieties recommended by those firms who rank as specialists of this flower, the cheaper sorts in their hundreds or thousands with a few choicer varieties as they can be obtained, the chief point being to choose sorts to command a flowering season from (weather permitting) the beginning of February until nearly

the end of May. I should, however, like to note that it is hardly advisable to attempt the naturalisation of Daffodils on a large scale on a poor soil with a light sandy subsoil coming up rather close to the surface. Under these circumstances where they are required in quantity, a portion of a slip garden may be set aside for them where the natural soil has been improved by cultivation, and where space is limited they can be planted occasionally between rows of Red Currants, Gooseberries, &c. The single varieties of Pyrethrums are most in request for cutting, and if the stock is to be increased, they may be split up and replanted before the approach of sharp weather. They are at their best in a fairly stiff soil that has been well worked and a mulching should be given at planting time. The colours range from snow-white to intense crimson and deep maroon, and, as noted in the case of new Phloxes, the varieties of more recent introduction are not only altogether finer in flower, but the individual petals are larger, more thickly set and of much better substance, considerably enhancing their value in a cut state.

**SPANISH IRISES.**—These may now be planted where space will permit fairly close together, as the growth, in comparison with that of some sections of the family, is small. The bulbs can now be obtained cheaply by the thousand, and such a quantity would give many shades of colour and varied forms. As they are over rather early in the season, they should be planted at a sufficient depth so that some dwarf plant may occupy their place later in the year without injury to the bulbs. Among useful flowers for summer cutting the Montbretias take high rank. To make sure of early flowers they should be well mulched in winter, or if the weather proves very sharp, the young growth that is pushing will be cut hard back and the flowering season thereby considerably delayed. This system of mulching will also be put in force in the case of *Gypsophila paniculata*, that invaluable plant alike for flower garden work and for cutting. Where unprotected, it succumbed to the exceptional weather in February, 1895. With the single exception of the Rose, no flower is so much in request for small vases and button-hole work as the Carnation, and as one does not always care to cut from the beds in the flower garden, it is advisable to plant a batch for cutting on some prepared border. Good hardy sorts of distinct shades that will throw plenty of flower and are non-splitters are the best for the purpose; the old white and crimson Cloves—if the latter will not do well, Murillo may be substituted—Ketton Rose and James Kirkpatrick are serviceable sorts. At one or two summer shows where dinner-table work entered rather largely into the arrangements, *Papaver nudicaule* was more in evidence than any other flower, and seems growing in favour with each succeeding year. Having acquired a good batch of the different shades from seed, I planted them as tiny little things on a rather stiff border that was already partly filled with bush Apples, keeping them of course well away from the trees. They grew amazingly, the amount of flowers obtained being very large, and this section is additionally valuable from the fact that it is not short-lived like the majority of Poppies, but will keep flowering away for several months. I had to move the stock of *Statice latifolia* early in the year, and, the dry weather following, it has not taken kindly to its new quarters, not sufficiently so, at any rate, to give a good supply of its long panicles of flowers so acceptable for cutting at this season of the year. The very dry time was also answerable for a comparative failure with the Spiræas, many spikes of flower not developing at all but literally drying up. The best results were obtained from a batch of *S. astilboides* planted under a north wall in a rather stiff, moist border. I removed all the imperfect flower-spikes from other varieties, and the rains commencing about the middle of July set the foliage up wonderfully, but the check had been too much for the plants, and the small flower-buds showing low down the stems did not develop sufficiently to recompense for the loss of the earlier bloom. When

the Starworts and the perennial Sunflowers make their appearance there is never any lack of flowers, and, with no frost up to the time of writing (October 14), the display in 1895 is naturally prolonged and the supply of cut flowers abundant. One of our most welcome autumnal flowers is certainly *Aster Tradescanti*. It is used in a cut state in many ways and for many different purposes, and in all bears itself bravely and well. Let me recommend for dinner-table work this Starwort associated with the purple *Cosmos bipinnatus*, an arrangement with very common flowers, but hard to beat with choicer things. Both are of graceful habit and stand well in a cut state, whilst one has only to pick a flower from the one and a spray from the other and place them together to see what a charming blend of colour is obtained. The latest Starworts we have are *diffusus*, *horizontalis*, *pendulus*, and *grandiflorus*, and, as previously advised, it is desirable to plant these in such a position that they can receive a little protection in the shape of tiffany when the glass drops below freezing point. The earlier of the white flowering *Chrysanthemums* are either in flower, or soon will be, and the last-named of the three Starworts—*grandiflorus*—will be found very serviceable to mix with the *Chrysanthemums*. Among the very best of the annuals of the present year has been *Cosmos bipinnatus* in the three shades of white, pale rose, and the purple mentioned above, as associating so well with *Tradescanti's* Starwort. Given plenty of room, so that individual plants can develop fully, they grow quite 6 feet high and continue furnishing plenty of bloom until the frost cuts them down. The flowers look very fragile, but stand remarkably well; indeed the placing into water seems almost to give additional stiffness to the flower-stems.

Claremont.

E. BURRELL.

**Delphinium Breckei and its variations** from seed.—Some three or four years ago I got from a leading Scotch florist and nurseryman a plant or two of the above-named most charming dwarf deep blue Larkspur, obtained rather over twenty years ago by the late Doctor Breck, and which has since borne his name. At the same time I also received a plant of the pure white-flowered form of this plant, and though they are both perfectly hardy and almost, if not quite, perennial, as it was rather late in the year when they came and they were both covered with flower-buds, I grew them both in pots in the cold greenhouse. After blooming profusely they both of them ripened a fair quantity of seed, which was carefully saved and sown in two pots. Nearly every seed came up, and the following spring the seedlings were planted out in two lots in a nursery bed. When they came into flower in the early summer I was much surprised to find that every plant of both lots of seedlings produced deep blue flowers without a single white among them. The plants in due time again seeded, and amongst a bed of some hundreds of seedlings, all from blue flowers, have now appeared two plants bearing pure white flowers. Being without the white variety at the commencement of this summer, I sent to the same nurseryman for four young plants of it, which I certainly expected would not cost me more than 1s. each, and was much surprised to find them charged at the comparatively high price of 2s. 6d. each. A prettier bed than one filled with this neat growing deep blue Larkspur one could not have in a garden, and if not allowed to seed it will continue blooming on the side shoots till quite the end of the autumn.—W. E. GUMBLETON.

**Crocus speciosus.**—Every year I am constrained to call attention to this beautiful species. It has been blooming abundantly for three weeks past, and it is seen at its best when it has been carefully planted, say, a half dozen corms in a patch in good soil, and then left alone. It spreads quickly, and a cluster which has had two or three years' development blooms very freely. It should be remembered by those unacquainted with the

species that it is a nude-flowering type, throwing up its bright violet flowers in autumn and its grass in spring. For exquisite beauty I do not think we have any spring-flowering *Crocus* which can compare with it.—R. D.

#### CAMPANULAS.

No rock is too high, no vale too low  
For its fragile and tremulous form to grow;  
It crowns the mountain  
With azure bells,  
And decks the fountain  
In forest dells;  
It wreathes the ruin with clusters grey,  
Nodding and laughing the live-long day.

MISS TWAMLY.

It would be difficult indeed to name a genus of flowering plants so endeared to lovers of bardy flowers as that of the Hairbells, or Bellflowers. Campanulas were among the most favoured flowers in the gardens of our ancestors many generations ago, and favourites they are still to the present day. Other flowers have come into fashion and have in due course been discarded for the fashions and fancies of more recent times, but the Bellflowers have held their own, and there is scarcely a garden in the land, from the luxurious pleasure grounds surrounding the mansion of the squire to the humble cottage garden of the peasant, where Bellflowers of one sort or another do not form a conspicuous feature. Such general popularity cannot be attained by any species of plant without decided merit, and great merit from every point of view is certainly possessed by the genus *Campanula*. Not only are most Bellflowers very easy to cultivate, but their variety is so enormous, that plants to suit all sorts and conditions may be chosen from their ranks; and it has been truly said that a garden might be made beautiful for the whole summer season by means of Campanulas alone if the varieties chosen are such as would furnish blooms in succession. We may choose from kinds growing only 2 inches or 3 inches above the ground to such as would attain the stately height of 5 feet to 6 feet; we may have Bellflowers which bloom in May, or we may choose varieties which will last till September; we may grow Campanulas which would be useful as cut flowers for indoor decoration, and we may grow such as would permanently adorn a rock garden intended for the choicest gems of the alpine flora. We may grow bold, upright Campanulas that would brighten the margins of shrubberies and herbaceous borders on a large or small scale, and we may grow kinds with pendent shoots fit for the window boxes of a cottage or as basket plants for banging in the verandah of a mansion. Surely such all-round usefulness deserves to be recognised, and it is no wonder, therefore, that the Campanulas enjoy such universal favour not only in this country, but all over the world.

The natural distribution of Campanulas is a very wide one. They are found in every part of the globe, from the wilds of Siberia to the sunny tropics, sometimes on the fertile soil of the plains and valleys, and sometimes covering the rocky slopes of mountains and ascending to the height of the snow-line. The Bellflowers comprise a genus of between 200 and 300 species, but by far the greatest number of these are indigenous to the south of Europe, especially the mountains of Southern France, Spain, Italy, Greece, Turkey and many islands of the Mediterranean Sea. The species which are considered natives of Great Britain are very few, and in Sir J. D. Hooker's "Students' Flora of the British Islands" (third edition) only eight

species are enumerated. In Central Europe, too, there are not a very great number of species found in a wild state; thus, for instance, Dr. August Garcke's "Flora of North and Central Germany" describes only twenty-five varieties.

beautiful *Campanulas* not mentioned in this paper, but, unless the selection is intended for a botanical collection, the names here given will be found sufficient for most gardens.

Much might be said with regard to the

*Campanula garganica.* (Fig. 4.)

In America the number of native species is much smaller still. But in spite of the comparative scarcity of native *Campanulas* in Northern Europe, and in Great Britain in particular, there is perhaps no country in the world where the introductions from the southern mountains have found a more welcome home than in these islands, where the climatic conditions are so favourable to the Bellflowers, that only very few of them require any special attention, but mostly take care of themselves when once established.

The object of this essay is not to give a synopsis of all the *Campanulas* grown in Great Britain, but rather to select only the very best and to describe a few of the most interesting sorts. As I also propose to give a few hints about the arranging of *Campanulas*, I think I cannot do better than divide my subject, not according to the botanical distinction of the various species, but from a practical rather than a scientific point of view. With this object, I will divide the Bellflowers into four classes, according to the purposes for which they are best suited, viz. :—

SECTION I.—Dwarf *Campanulas* suitable for the select part of a rock garden.

SECTION II.—Dwarf *Campanulas* generally suitable for rock gardens or front of borders.

SECTION III.—*Campanulas* of medium size mostly suitable for borders.

SECTION IV.—Tall *Campanulas* for borders or isolated specimens.

That this form of division is not scientific I am quite willing to admit, but it is of practical value to those who are unacquainted with some of the names, but would choose their plants according to the purpose for which they intend to use them regardless of botanical distinctions. In nearly every case the descriptions are based on my own observation, and in recommending this or that position for a plant I have been guided by practical experience. There are many other

arranging of *Campanulas*, but I must be content with briefly mentioning one or two of the most important points. Whether on rockwork or in borders, most hardy flowers look infinitely better arranged in irregular groups of varying sizes than dotted about singly, and *Campanulas* are no exception to that rule. On the contrary, we might even have different groups of Hairbells adjoining each other if care is taken to blend their colours harmoniously, which should be an easy matter considering the many shades of colour from pure white to all shades of blue and purple. Of other hardy plants which might be associated with *Campanulas* there are perhaps none better than the perennial Poppies. The contrast of colour between these and the Hairbells is one of mutual advantage to both, and as they flower at the same time each is enhanced by the other. *Campanulas* of the dwarfiest types in the rock garden may be associated with the varieties of *Papaver alpinum*. Hairbells of medium size go well with Iceland Poppies (*Papaver nudicaule*), and the tall *Campanulas*, such as *C. pyramidalis*, *C. Medium*, &c., are excellent companions in every way to the giant Poppies of the *Papaver orientale* type. There are, of course, many other classes of hardy plants suitable for associating with Bellflowers, but I know of none that would surpass the Poppies. As the nomenclature of *Campanulas* is in a somewhat confused state owing to some of the varieties being known under several different names, I have thought it best to add where possible the authors of the names.

SECTION I.—RARE AND CHOICE KINDS OF DWARF *CAMPANULAS* SUITABLE FOR SELECT PART OF A ROCK GARDEN.

It is not absolutely necessary that the Bellflowers described under this section should be grown in a rock garden. They will, for the most part, succeed in an ordinary border containing sandy loam mixed with a few stones, but as their native home is among the rocks, it is in a similar position that they would give the most satisfactory results in our gardens. Several of those here enumerated come from very high altitudes, and a cool position such as they would find on the north side of a rock garden is essential to their well-being.

*CAMPANULA ALLIONI* (Vill.).—This little gem is also known under the names of *Campanula alpestris* (All.) and *Campanula nana* (Lam.), and is a native of Piedmont. The corolla is very large for a plant growing seldom more than 3 inches or 4 inches in height, purplish blue (rarely white), urceolate in shape, almost erect on a slender stalk, slightly covered by pubescence. The leaves are linear-lanceolate, with margin entire or very slightly crenate. It is an excellent rock plant, and though requiring plenty of moisture, it should have a well-drained position, and is therefore best grown in a narrow crevice filled with sandy loam and an abundance of small stones and grit. Flowering time, May to August.

*C. CENISIA* (Linn.).—As its name implies, the native home of this little gem is Mont Cenis, but it occurs wild in many other parts of Switzerland and Italy, generally at very high altitudes. I saw masses of it quite close to a glacier in the neighbourhood of Bourg St. Pierre, growing, in fact, in the moraine of the glacier in company with *Linaria alpina* and *Ranunculus glacialis*. It has solitary deep blue flowers on short stems only 2 inches high. The radical leaves are obovate, while those of the stem are ovate-oblong. It flowers in June.

*Campanula Medium.* (Fig. 10.)

Owing to the high altitude at which this little gem is found in its native country, it seldom does well in English rock gardens if planted on a dry slope exposed to the full sun, but it does remarkably well if planted on the north side of a

rock garden where it can have plenty of light, but where the air is cool and moist.

*C. ERINUS* (Linn.).—This is another little gem, but unfortunately not of very long duration. Its native home is on the shore of the Mediterranean. The flowers are very freely produced and appear in semi-prostrate long racemes, each bearing ten to twenty flowers. The individual blossoms are pale blue with light centre, and the star-shaped corolla is scarcely half an inch in diameter, with very acute narrow lobes. The style is conspicuous by its great length and is of the same shade of blue as the corolla. The blossoms often last till September. The small bright glossy green leaves, varying from a quarter of an inch to three-quarters of an inch in diameter, are cordate in shape, but very deeply cut, the pointed lobes being very conspicuous.

*C. EXCISA* (Schleich).—A rare and interesting species from Switzerland, usually found at very high altitudes; the flowers are pale blue and the lobes of the corolla are very deeply cut. At the base between each two lobes this incision takes the shape of a round hole, and it is probably this peculiarity which suggested the very appropriate name. It usually blooms in June, but I saw it in blossom as late as August on the rockwork at Kew, where it seems to thrive remarkably well. The leaves are linear-lanceolate with margins entire. The whole plant is not more than 4 inches or 5 inches in height and likes a position not fully exposed to the sun, but where the air would be cool and moist.

*C. RAINERI* (Perp.).—A native of high mountains in Italy and some parts of Switzerland. It is one of our choicest rock plants, but the true species is rare in English gardens, and several forms of the hybrid *Campanula* G. F. Wilson are often seen under the name of *C. Raineri*. The latter, however, is quite distinct, and one of the best means of identifying the true *C. Raineri* is by the leaves, which are of a deeper green and more tomentose than in the hybrid species referred to. The flowers are solitary, large in size, of turbinate shape and dark purplish blue in colour. The leaves are sessile, obovate and ovate with serrated margin. The plant is seldom more than 3 inches in height and enjoys a well-drained, warm, sunny position. It is well worth a place among choice things in the select part of the rock garden.

*C. WALDSTEINIANA* (Roem. and Schult.).—Croatia and Hungary are the native homes of this charming Bellflower, which grows only 4 inches to 6 inches high, and makes an excellent rock plant in many English gardens. The flowers appear in corymbose racemes of from five to nine blossoms each, the individual blooms having an almost rotate corolla a quarter of an inch in length and three-quarters of an inch in diameter, of a pale purplish blue colour, with lobes spread out almost flat so as to give the flower quite a star-like appearance. A dark spot marks the throat of each flower. Conspicuous also is the large white club-shaped pistil, which is twice the length of the corolla and bears a yellow stigma. The calyx is very short, and its acicular lobes are recurved in a peculiar way. The pedicels are varying in length and bear several bracteoles. The stems are very rigid and bear somewhat fleshy sessile leaves of greyish green colour, alternately arranged, of lanceolate shape, with margins slightly serrate dentate.

*C. ZOYSI* (Wulf.).—This is a native of the Austrian Alps, and a rare little gem for the rock garden. It is, however, very seldom seen to perfection in English gardens, probably on account of its being very liable to perish during winter through excessive moisture. The best lot I have seen I noticed in a rock garden in Essex, where a large overhanging ledge of rock formed a kind of cave. Here it was blooming profusely in August. The plant grows scarcely more than 3 inches or 4 inches in height and bears pale blue flowers of drooping habit, with a rather long cylindrical or tubular corolla. The radical leaves are obovate, while those of the stem are lanceolate.

## SECTION II.—DWARF CAMPANULAS GENERALLY SUITABLE FOR ROCK GARDEN OR FRONT OF BORDERS.

This section comprises the greatest number of Hairbells, and from these I have selected what appear to me the best and most suitable for the purpose indicated. Some of the varieties here mentioned are excellent rock plants, especially those with long pendent shoots, which would display their flowers to the greatest advantage if allowed to hang down over the rocks. Others, again, form compact carpets most suitable for level ground, either on rockwork or border. Most suitable edging plants are also contained among this section.

*CAMPANULA ALPINA* (Jacq.) is a native of the Carpathian Mountains, and varies from 3 inches to 8 inches in height. The flowers are disposed on an erect pyramidal raceme and deep blue in colour. The flowers consist of a tube about 1 inch in length and half an inch in diameter, with triangular lobes completely turned back. The pistil is large and club-shaped; the lobes of the calyx are linear and as long as the tubular part of the corolla; the leaves are sessile, lanceolate, obtuse, of a dark green colour with margins entire, but covered with hair to such an extent as to give the whole plant a shaggy appearance. It is a capital rock plant and very easy of cultivation; it flowers in June and July.

*C. BARBATA* (Linn.).—This variety (see illustration fig. 11) varies much in size. At high elevations in the Alps of Southern Switzerland I saw large numbers of it no higher than 2 inches or 3 inches, but as a border plant in English gardens it will often attain a height of 9 inches or more, and its leaves will be coarser in proportion. In the Alps its pale porcelain-blue flowers close to the ground are exquisite. The blossoms are perfectly smooth outside, but covered with hair on the inside of the corolla; they appear in a loose raceme from the axils of the leaves, which are lanceolate in shape. In the rock garden it should be grown in poor, stony soil, as it is apt to become somewhat coarse when grown in rich soil.

*C. CASPITOSA* (Seop.) (see illustration fig. 1).—This is perhaps still better known under the name of *C. pumila* (Curt.), and is one of the most useful plants in our gardens. It flowers almost continually from May to August or September, and quickly forms a very neat and compact carpet. The leaves are almost orbicular or ovate, slightly lobed, not much more than a quarter of an inch across on short petioles, and of bright green colour. This dense carpet is profusely studded with drooping flowers either blue or white in colour. The fact that it will flourish anywhere has made it a great favourite either for edging, rockwork, or border, and it certainly deserves its popularity. It is a native of South Europe.

*C. CARPATHICA* (Jacq.) (see illustration fig. 2) is a native of Hungary and adjacent districts, and as much a favourite as the last named variety (*caespitosa*). The large deep blue or white flowers are very showy, and last for a considerable time. The flowers are often more than 1½ inches in diameter, and are usually 8 inches to 10 inches in height. The leaves are 1 inch to 1½ inches long and three-quarters of an inch to 1 inch wide, cordate, involute, coarsely dentated, and deeply undulated. In the border large groups of this Bellflower are most effective. If planted in the rock garden it is best arranged in masses not on, but between the rocks, or forming a carpet between taller plants in the background. The white form (*C. carpathica alba*) is also most effective and equally easy of cultivation.

*C. CARPATHICA BELVIFORMIS* (Lam.) is a sub-variety distinguished by its very large pale lilac or heliotrope-coloured blossoms. The flowers are fragrant, often as much as 2 inches across, somewhat flat or saucer-shaped and appear in loose panicles. The leaves are ovate or cordate, toothed at the margin. Though a native of the island of Crete, it does very well in Great Britain and Ireland.

*C. C. TURBINATA* (Schott) is another sub-variety of *C. carpathica* with flowers more bell-shaped, turbinate, dwarfer and more compact. The flowers are often 2 inches across and of a deep purplish blue. The leaves are cordate-lanceolate with crenate-serrate margin. It is an excellent rock plant, and as it is one of the easiest of cultivation, it does also remarkably well in the front part of an ordinary border. It grows seldom more than 6 inches in height.

*C. C. TURBINATA PALLIDA*, with flowers of a pale blue colour, but in other respects similar to the former, is a very effective sub-species, though rarer in cultivation.

*C. C. T. G. F. WILSON* (see illustration fig. 3).—This interesting hybrid was the result of a cross between *C. c. turbinata* and *C. pulla*, and is certainly very distinct, combining the large bell-shaped flowers of *C. c. turbinata* with the splendid dark colour of *C. pulla*. It is very compact and dwarf in habit, and hence an excellent rock plant, well known to lovers of hardy plants. The leaves are small, very hairy, ovate in shape, with a crenate-serrate margin.

*C. ELATINES* (Linn.) is found wild in Italy and Austria, and though somewhat rare in English gardens, is an excellent variety for the rock garden on account of its dwarf, compact growth. The flowers are deep blue, borne in a paniced raceme not more than 5 inches or 6 inches high. The cordate leaves are dentate at the margin. It does well in light stony soil.

*C. FRAGILIS* (Cyrill.).—This is another Italian species, known also as *C. Barelieri* (Fresl.). It would probably require protection in the north of England or Scotland, but here in Devon it is, as a rule, perfectly hardy. Its long trailing shoots are covered with rather pale purplish blue flowers with white centre. The leaves are ovate and deeply lobed. On account of its trailing habit it makes an excellent basket plant for suspending from the roof of a verandah, and is also most suitable for window boxes or for covering prominent stones in the rock garden.

*C. GARGANICA* (Tenore) (see illustration fig. 4).—This is a native of Italy and Greece, and a most valuable addition to our garden flowers either for rockwork or border. As the illustration shows, it is very free-flowering, and the flowers flat, with the lobes of the corolla so widely spread as to appear almost like little stars. The blooms are pale blue with whitish centre, and last throughout June and July. The leaves are deep green and glossy, on petioles about 1 inch in length; they are cordate or reniform when flattened, but biserrate, deeply lobed and involute. It will do well on rockwork in a half-shady position.

*C. G. HIRSA* (see illustration fig. 5).—This handsome sub-variety is also of Italian origin, and, though the small illustration might imply that it is smaller than the last named (*C. garganica*), it is really more vigorous than that variety. It bears in June numerous long racemes of twelve to fifteen flowers each, very similar to those of *C. garganica*, but a trifle larger. The leaves also are larger and quite tomentose, which among hardy plants generally is a sure sign of their loving a position fully exposed to the sun. For sunny rock gardens there are few plants to equal this one, but it must of course be planted where it cannot overgrow smaller subjects.

*C. HAYLOGGENSIS* (Hort.) is an interesting hybrid, raised at Hay Lodge, Edinburgh, from a cross between *C. carpathica* and *C. pusilla*. I have only seen it flowering at Kew, but it appears to be a good thing and flowered abundantly on the rockwork. The colour is light blue and the flowers are somewhat saucer-shaped. The plant grows 6 inches to 8 inches high and lasts in bloom till August. The radical leaves are orbicular, while the cauline ones are ovate, with a dentate margin.

*C. ISOPHYLLA* (Moretti).—This native of North Italy also bears the name of *C. floribunda* (Viv.), and its white variety (*C. i. alba*) is illustrated in the engraving fig. 6. *C. isophylla* has a cymose inflorescence and pale blue, flat, saucer-shaped flowers more than 1 inch in diameter. The broad lobes of the corolla are very obtuse, and another

*Campanula carpathica.* (Fig. 2.)

*Campanula isophylla alba.* (Fig. 6.)

*Campanula barbata.* (Fig. 11.)

*Campanula turbinata* (t. F. Wilson. (Fig. 3.)

*Campanula caspitosa.* (Fig. 1.)

*Campanula Portenschlagiana.* (Fig. 8.)

*Campanula Loreyi.* (Fig. 7.)

*Campanula aarqanica hirsuta.* (Fig. 5.)

*Campanula pusilla.* (Fig. 9.)

conspicuous feature is the style, which is comparatively large and projects quite an inch from the centre of the flower. The leaves have petioles 1 inch to 2 inches long; they are involute, cordate, slightly hairy and coarsely serrated at the edge. It is not found in cultivation quite so often as its white variety (here illustrated), but both are excellent rock plants or basket plants, and their pendent shoots laden with flowers should always have a position that would show them off to advantage. Their cultivation presents no difficulties whatever, and I have seen them do equally well in a sunny or in a half-shady position.

*C. LOREYI* (Pollini) (syn., *C. ramosissima*, Host.) (see illustration fig. 7).—Unfortunately this interesting species from Italy and the Austrian Alps is only annual, but it is quite worthy of a place among dwarf plants, and might be sown in the open border in spring. It is from 6 inches to 12 inches high and produces tubular flowers of rather inflated appearance. These are almost white at the base, but are shaded towards the apex of the lobes with blue and violet. The stems are long and erect and have lanceolate and linear leaves.

*C. MOLLIS* (Linn.).—Though the native home of this Bellflower is on the shores of the Mediterranean, it has nevertheless proved itself to be perfectly hardy in this country and stood the test of the last severe winter. It is most useful for rockwork or border and easy of cultivation. The flowers are of a dark purplish blue and very freely produced during May and June. The plant is from 6 inches to 8 inches high and soon forms a compact spreading carpet of glossy green leaves, which are ornamental, even at midwinter, by their brightness of colour. The leaves are on rather long petioles, and when flattened out appear reniform, but they are involute to such an extent as to appear almost funnel-shaped. The margins of the leaves are bi-serrate and very deeply cut.

*C. NITIDA* (? Soland), also known as *C. planiflora*, is an American species and a decided acquisition. It is fit to occupy some choice sunny corner in the rock garden. The flowers are blue and very flat, saucer-shaped, almost rotate. There is also a white variety, viz., *C. nitida alba*, the flowers of which remind one of *Nierembergia rivularis*, but they are more wax in appearance. Both varieties are of very slow growth, dwarf and compact. The leaves are arranged in whorls, forming very dark green shining rosettes, the individual leaves being about  $1\frac{1}{2}$  inches long and a quarter of an inch wide, very leathery in substance and crenate, slightly undulating at the margin.

*C. PORTENSCHLAGIANA* (Roem. and Schult.), (see illustration fig. 8).—This is a native of Dalmatia, and is synonymous with *C. muralis* (Portenschl.). It is a most useful plant for the quick formation of a dense dwarf carpet, and is suitable for almost any position. It grows from 6 inches to 8 inches high, and has a bell-shaped corolla about half an inch in length, and a diameter of three-quarters of an inch from lobe to lobe. The lobes are recurved and rather obtuse. It flowers most abundantly during the whole of the summer, the blossoms being disposed in paniced racemes. The radical leaves are reniform, smooth dark green, and more than an inch in diameter; the cauline leaves are smaller, and have coarsely serrated edges. There is also a more robust variety named *C. P. major*.

*C. PELLA* (Linn.).—This native of South Eastern Europe is easily distinguished from all other Hairbells by its very dark colour, the flowers being of an intense dark purple-blue, almost approaching to black. It loves light sandy soil, and is an excellent rock plant, growing only 4 inches or 5 inches in height. The leaves measure less than a quarter of an inch across, and the indentations at the margin are very slightly crenate and dentate.

*C. PUSILLA* (Haeenke), (see illustration fig. 9).—By many botanists this variety is considered identical with *C. pumila*, and though a difference undoubtedly exists, it is questionable whether that difference justifies the retaining of a separate name. The *C. pusilla* here illustrated is an excel-

lent rock plant, and does well in gritty soil. The flowers are blue, and appear three to five on a stem with a campanulate corolla little more than half an inch in length. The radical leaves are orbicular, half an inch in diameter, serrate and slightly involute on petioles about 1 inch in length. The cauline leaves are linear and lanceolate.

*C. ROTUNDIFOLIA* (Linn.).—This British species is very widely distributed, not only in Great Britain, but also in most European countries, and even in Africa, North America, and parts of Asia. It varies according to situation from 6 inches to 18 inches in height, and has drooping flowers of a blue colour. The lobes of the campanulate corolla are recurved and rather short. The radical leaves are ovate or cordate, sometimes orbicular with a crenate margin. The cauline leaves are linear and almost entire. It is well worthy of a place in the rougher part of the rock garden or border. There is also a white form.

*C. ROTUNDIFOLIA HOSTI* is a handsome sub-variety of the former, distinguished by larger flowers of a deeper blue and by stronger wiry flower-stems.

*C. R. SOLDANELLEFLORA* is another very distinct form with semi-double blue flowers split into many narrow divisions, which remind one of the fringe of a Soldanella.

*C. SCHEUCHZERI* (Vill.).—This variety is, according to Garke's "Flora of North and Central Germany," considered to be only another variation of *C. rotundifolia*, and has from one to five large flowers of a deeper bell shape than the British species and with lanceolate leaves crenate at the margin. It grows about 6 inches high and is a native of South Europe. On rockwork and in borders it is effective and of the easiest cultivation. There is also a white variety under the name of *C. Scheuchzeri alba*.

#### SECTION III.—CAMPANULAS OF MEDIUM SIZE, MOSTLY SUITABLE FOR BORDERS.

It is somewhat difficult to draw anything like a hard and fast line where the sizes of plants are concerned, for the reason that even the same species will often vary in size if planted in another locality or under different conditions. The term "plants of medium size" is therefore rather indefinite, but I have used it for practical reasons, and the Campanulas mentioned under this section must be understood to mean plants generally varying from 9 inches to 18 inches in height, and only under exceptionally favourable circumstances exceeding a height of 2 feet. The Hairbells of this section are such as would not require the preparation of narrow crevices or any special treatment, but would grow in ordinary soil in the herbaceous border. It does not follow that they should not also be used in the rock garden, but where used for that purpose their proper place would be in large or small batches between the groups of rock rather than on the rocks themselves. All the varieties here mentioned will be found far more effective when they are combined together in the formation of large groups than when dotted about singly.

*CAMPANULA ABETINA* (Griseb.) is seldom more than 12 inches to 15 inches in height, and the large purplish blue flowers are borne in great profusion on slender, but wiry stems. The flowers are further distinguished from other varieties by being distinctly shaded with reddish purple. It is free-flowering and an excellent border plant.

*C. BERGHALTI* (Hort.).—This is a very handsome hybrid form of *C. Van Houttei* (Carr.), and, though little known at present, it is sure to become popular. It grows from 18 inches to 2 feet in height, and is most distinct. The flowers are disposed in strong racemes of from six to eight flowers each: they are axillary, with pedicels about 1 inch in length, and bearing two short bracteoles. The flower-buds are dark purple, but the pendent flowers when expanded are of a very

distinct pale lilac colour. Each individual corolla is fully  $2\frac{1}{2}$  inches in length and about three quarters of an inch in diameter, the tubular or cylindrical part of the corolla alone being quite 2 inches long. The lobes of the corolla are not recurved, but in a line with the tube; the interior of the corolla is covered with long silky hair to such an extent as to have quite a shaggy appearance. The style is very large, tapering towards the bottom, and covered with short hairs. The calyx-lobes are about 1 inch in length. The radical leaves are about 3 inches in diameter and remind one of those of the Nettle; they are wrinkled, cordate in shape, with a crenate margin, and covered with hair on both sides. Their petioles are 3 inches to 4 inches in length. The cauline leaves are sessile, or have their petioles expanded into a narrow blade; they are alternate at intervals of about 2 inches, and, like the radical leaves, rough to the touch, owing to a covering of bristly hairs. Towards the top the cauline leaves become much narrower. Flowering time from early August to September.

*C. GLOMERATA DAHURICA* (syn., *C. speciosa*, Hornem.) is one of the handsomest of early-flowering Campanulas. It flowers throughout May and June, growing about 15 inches or 18 inches high, and bearing terminal heads of numerous large tubular flowers of the deepest purple colour. The leaves are ovate or cordate,  $1\frac{1}{2}$  inches to 3 inches long, and 1 inch to 2 inches wide, covered with very short, stiff hairs, especially on the upper side, which has a rough surface. The petioles are a little longer than the blades, and in the case of young leaves striped with red. The margins are crenate. It is one of the most desirable plants either for border or rock garden, and is of the easiest cultivation.

*C. GRANDIS* (Fisch.) (syn., *C. latiloba*, De C.).—This is a very fine form for the border, where it will rapidly form a thick carpet of sessile, lanceolate leaves, throwing up flower-stems about 18 inches high, covered with large pale violet-blue flowers often 2 inches in diameter. There is also a very good white form under the name of *C. grandis alba*.

*C. HENDERSONI* (Hort.) is generally considered to be a form of *C. carpathica turbinata*, but it is certainly much more robust than that variety, and grows a foot or more in height. The dark blue flowers, each  $1\frac{1}{2}$  inches to 2 inches in diameter, are borne in short racemes of from six to nine flowers each. The lobes of the corolla are very obtuse, almost hemispherical. The stems are very thick, strong and wiry. The leaves are on petioles 1 inch to  $1\frac{1}{2}$  inches long, folded upwards through the middle, so as to appear almost conduplicate. They are ovate and ovate-cordate,  $1\frac{1}{2}$  inches long and about three-quarters of an inch wide, slightly hairy on both sides and with serrated margins.

*C. MACROSTYLA* (Boiss.).—This grows about 18 inches in height, and has large flat, purple flowers beautifully veined, and bearing in the centre the very large peculiar-shaped style from which the plant takes its name. It is, unfortunately, however, only of annual duration.

*C. RHOMBOIDALIS* (Linn.).—This is a very fine variety and well adapted for the rock garden or the border: it grows about 12 inches high and has blue flowers, which appear in July. Almost finer than the type is the sub-variety *Campanula rhomboidalis alba*, with pure white flowers. This has a large corolla of hemispherical shape, measuring more in width than in length. The style and stamens are very short and inconspicuous. The flowers are disposed eight or ten on a stem in an almost corymbose raceme, with the lower pedicels  $2\frac{1}{2}$  inches to 3 inches long, while those of the upper part of the raceme measure only about an inch. All pedicels have one or more bracteoles. The lobes of the corolla are slightly recurved. The radical leaves are sessile, linear-lanceolate, slightly crenate, 2 inches in length and little more than an eighth of an inch in width; towards the top of the stem the leaves become gradually narrow, quite linear or acicular, with margins entire. It is altogether a most

desirable species, but as its leaves and stems die down soon after flowering (July and August) it should be planted like an evergreen species.

*C. SARMAITICA* (Ker-Gawl)—also known as *C. gummifera* (Wild.)—is a native of the Caucasus, and grows from 1 foot to 2 feet high, with light blue, drooping flowers disposed in a long, loose raceme. It flowers during July and August. Its leaves are of a very dark green, wrinkled and leathery, of uniform and ovate-cordate shape, crenated at the margin and only slightly involute.

*C. THYRSOIDEA* (Linn.) grows about 18 inches high and is distinguished by its creamy yellow or sulphur-coloured flowers, arranged in a dense pyramidal spike. Unfortunately it is only biennial. The radical leaves are sessile, spatulate, about 2½ inches long and three-quarters of an inch wide, arranged in a rosette flat on the ground. The serration at the margin is very minute and the leaves appear almost entire. The cauline leaves are linear and lanceolate, and, like the radical ones, covered with long hairs at the margin.

*C. VAN HOUTTEI* (Carr.)—This is one of our finest border Campanulas, blooming in July and August. It has large, pendent, tubular flowers, of a deep dark blue colour, but is in other respects scarcely to be distinguished from its fine hybrid, *C. Burghalti*, which has been already described.

*C. VIDALI* (Wats.)—This handsome species from the Azores has beautiful white, wax-like flowers on stems about 18 inches to 2 feet long, and leaves more like a *Mesembryanthemum* than a *Campanula*. Though undoubtedly a rare and handsome species, it cannot be considered a hardy plant except during the summer months, and should be wintered in a frame or greenhouse. A full description appeared in *THE GARDEN* of August 24, page 136.

#### SECTION IV.—TALL CAMPANULAS FOR BORDERS OR FOR PLANTING AS ISOLATED SPECIMENS.

The Hairbells mentioned under this section are the giants of the family, varying in height from 2 feet to 5 feet, or even more. In planting they are best arranged in groups in the back part of the herbaceous border, but some of the rarest and handsomest kinds might with advantage be introduced as isolated specimens, either into a border carpeted with smaller flowers or by themselves on the lawn, or into places in the rock garden where it is desirable to emphasise a bold effect.

*CAMPANULA BONONIENSIS* (Linn.)—Of this fine border plant there are two varieties, one with bluish violet flowers, the other with pure white flowers. The plant is very widely distributed in Europe, and grows about 2½ feet in height. The flowers are arranged on a long, narrow, pyramidal spike, about 2 feet in length, and bear from sixty to a hundred small flowers, with acutely-lobed corollas scarcely more than an inch in length. The leaves are alternate, sessile, amplexicaul, ovate-lanceolate, serrated at the margin.

*C. LACTIFLORA* (Bieb.), also known as *C. celtidifolia* (Boiss.), is a native of the Caucasus and Siberia, and attains in our gardens a height varying from 2½ feet to 5 feet. It is a first-class border perennial, with pale blue flowers arranged in loose panicles, and flowers from July to September. The leaves are ovate-lanceolate.

*C. LATIFOLIA* (Linn.)—This is a stately native species, growing 3 feet or 4 feet high, with large blue or white flowers. The flowers are axillary and have large leafy bracts, which give the whole raceme a very leafy appearance. The lobes of the corolla are acuminate. The leaves are large, many being quite 6 inches long, oblong, ovate, bi-serrate, covered with soft hairs. Two fine sub-varieties are *C. latifolia eriocarpa* (Bieb.) and *C. l. macrantha*; the latter has larger flowers than the type, and all are excellent border plants.

*C. MEDIUM* (Linn.) (see illustration fig. 10).—This is our old familiar friend the Canterbury Bell, so well known to everybody as to need no further description. The illustration represents

the Hose-in-hose or Cup and Saucer variety. There are several double and semi-double forms, but as the plant is only biennial it is necessary to keep up a fresh supply of young plants, which is easily managed by sowing in pots or pans in early spring and planting out when strong enough. The plants will then flower the following season, and must be reckoned among our showiest border subjects.

*C. PERSICIFOLIA* (Linn.) (see illustration fig. 12).—This handsome Bellflower is sometimes found naturalised in woods in various parts of Great Britain, but the cultivated form is very much finer in all its parts. The large blue flowers are borne in a loose raceme 2 feet to 3 feet high, and are blue or white, excellent for cutting. The leaves are obtuse, spatulate, 3 inches to 4 inches in length, leathery, and slightly serrated. Of this *Campanula* we have a great many sub-varieties, as *C. p. flore-pleno* with double flowers, *C. p. alba* (see illustration), *C. p. alba coronata*, with semi-double flowers, *C. p. alba fl.-pl.*, with magnificent double flowers excellent for cutting. Of all the *Campanulas* none can surpass the following:—

*C. PERSICIFOLIA ALBA GRANDIFLORA*.—This is the queen of Hairbells, a truly noble plant fit for growing as an isolated specimen in the rock garden or in groups in the border. It is like the *C. persicifolia alba* here illustrated, but the pure white flowers are much larger, and often measure 2½ inches across. It is excellent for cutting, too, and second to no other hardy perennial.

*C. PYRAMIDALIS* (Linn.) (see illustration fig. 13) is the giant among *Campanulas*, attaining often a height of 5 feet to 7 feet. Young plants give the finest flowers, and it is therefore best treated as a biennial. Though somewhat stiff in appearance it is an excellent border plant, and also well suited for being grown in pots to decorate verandahs, conservatories, &c. It is one of our oldest hardy flowers and most effective. There are several shades of colour, from pure white to blue. The flowers are densely crowded in long pyramidal spikes and the leaves are large, ovate. The plant prefers a slightly shaded position to one fully exposed. F. W. MEYER.

*Exeter.*

**Eritrichium.**—About twenty years ago the late Mr. James Backhouse received several species of *Eritrichium* from N. America, all of which, with one exception, proved to be very coarse, weedy things. The only one that was in any degree worth growing was *E. aretioides*. Has any reader ever come across this or any other American species that is worth anything?—W. M.

**Colour in Carnations.**—Possibly one of the most vexatious items, particularly in so far as appertains to new plants, is the catalogue descriptions of their colours. In not a few instances some popular shade of colour has never existed beyond the imagination of the raiser or introducer. Whether this is the result of colour blindness or ignorance matters little, or even if it is design the case is much the same, and in the end only tends to make possible purchasers of new plants the more cautious, for while one may pardon in a measure exaggerated colour descriptions when any particular shade exists, it really can serve no useful purpose to attach colours which do not exist at all. For instance, at page 218 of *THE GARDEN* the American *Carnation* William Scott is described as pink, which of all shades in *Carnations* is perhaps the most sought after. Now, I had always regarded the well-known Miss Joliffe as having flowers of a good representative pink shade, and if this is really so, then those of William Scott have certainly nothing to do with this shade at all. I do not know what precise shade an artist such as Mr. Moon would give to this flower, but it appears to me a rose-magenta, a colour exceedingly common among border kinds. Then again, Daybreak is called a light pink, whereas this kind has more white in it than even the old blush Malmaison. Daybreak also bursts the pod very badly. Apart from the colour of William Scott the plant has a gross habit of growth, while the flowers are exceedingly com-

mon-looking, and the great saw-edged petals are not at all pleasing. For shades of pink such as Miss Joliffe, Reginald Godfrey and others have, there is abundant room, and while such are procurable, the florists, who virtually control the cut flower trade, will not take kindly to such as William Scott. Though a larger flower than Miss Joliffe, it lacks the exceeding beauty and refinement of this variety. Indeed, the latter, where it can yet be grown, has scarcely any equal either for quality of bloom, freedom and continuity of producing its flowers, or its exquisite shade. The great majority of growers, however, fail to manage it now, and the constitution appears gone. Even growers who have been accustomed to have it by the ten thousand have, quite failed with it during the past few years. In its bushy habit and perfect calyx it is an ideal *Carnation*, and of such a standard only very few ever come to the front. Some of the seedlings raised from this variety, carefully fertilised with its own pollen and protected afterwards, resulted in scarlets and brick-red shades. Nothing to compare with the parent, so far as I am aware, has been raised from it.—E. J.

## STOVE AND GREENHOUSE.

### WINTER-BLOOMING CARNATIONS.

THE information given on these is often very misleading, especially to those who are forming a collection, so many varieties being named that are not Tree *Carnations* at all and will not flower in winter except by mere chance. As a rule *Carnations* are grown in pots for cutting, and any variety that only produces a few blooms is not worth the labour and house room. Since I formed the collection here I have tried and discarded many so-called good varieties sent out with grand names, but utterly useless where the flower basket has to be filled in mid-winter. A few years ago a good deal was written in praise of seedling *Carnations* for winter work, and I was induced to try them, but I grew none a second time, as not one out of a whole batch, and that obtained from an expensive packet of seed, was comparable to the old standard sorts, such as Miss Joliffe, *Alécatiere*, *Winter Cheer* and *La Neige*. The last comparatively new Tree is the greatest advance that has been made for many years. I still have Mlle. Carle, but shall not grow it after this season, *La Neige* being so much more free in growth and flowering and a non-splitter. I do not think *Uriah Pike* will prove itself a free winter bloomer, although it may flower well in spring. My plants are extra large and robust with abundance of side shoots, which have been well exposed to the sun, but at present only a solitary bloom here and there is visible, whereas every plant of the old sorts is covered with blooms and buds in every stage of development. Of course, a good spring bloomer is valuable, as it keeps up the supply after other sorts are on the wane, so that should *Uriah Pike* prove itself to be this, it will be well worth growing in pots, as its colour and fragrance are very beautiful. Our plants look most promising, having just been housed in a rather lofty structure on a stage close to the roof-glass, air both at the top and front ventilators being admitted day and night. It is a good plan to fumigate the plants immediately they are taken in, as the somewhat drier atmosphere is almost sure to bring greenfly, and this must not be allowed to make headway. An intermediate temperature recommended by some encourages this pest and causes a weakly, unproductive growth. So long as actual frost is excluded the plants will be safe. In regard to feeding, I give no manure water during summer growth, but water twice weekly

in winter when the plants are taxed by blooming with diluted farmyard liquid the colour of pale ale. During October the plants are gently dewed over with the syringe on fine sunny days and the stage and floors kept moist. During November, December and January draught is avoided, as it soon produces mildew. Last January I layered a number of strong shoots of Miss Joliffe and La Neige on the plants as they stood in the house, putting a little Moss in the incision to keep it open and also mossaing the stem round; these rooted freely, the young rootlets showing themselves through the Moss at the end of February. They were detached and potted, Moss and all, into small pots and grown on through the summer. They are now very large bushes, twice the size of those struck from cuttings in spring in the usual way.

J. C.

#### DWARF POINSETTIAS.

MENTION is made at page 265 of the difficulty often experienced in obtaining dwarf plants of the above for vases and similar work, and a method of overcoming the difficulty is also alluded to. This, however, is virtually spoiling a large plant to make a small one. Here is another way of obtaining dwarf plants for the purpose named by "J. C.," and one which means simply the more complete utilisation of old stock plants. Many gardeners fail to root Poinsettias by growing sappy cuttings in too much heat. To avoid this, in May, when the usual stock of these plants has been some time rooted, place the old stock plants either in cold frames or in the open if weather permits. In the frames, however, the old plants will presently produce short, serviceable cuttings, or, if there is any fear in this respect, keep the plants in a slightly warmer place till 3 inches of fresh growth have been made. Now remove to a pit or frame, and keep them quite on the dry side at the root for the first fortnight. By giving air increasingly day by day the lights may be left off altogether and the plants subjected to full light. A few days of this treatment and you have short, sturdy cuttings, totally distinct from the soft, sappy ones produced in greater heat and moisture. Secure these cuttings with a heel attached when 4 inches long, and insert singly in small pots. In any gentle bottom heat, as, for example, a manure frame, such cuttings root quickly and with greater certainty than those produced in heat. When well rooted and gradually hardened off the plants should be grown in the open in full sun, and at all times given moderate supplies of water at the root. Thus grown and fully exposed, growth is somewhat slow, and short-jointed, well-ripened wood resulting. And the result of well-ripened wood is known to all. From the cutting pot the young plants should be shifted into 4½-inch pots, and in these allowed to develop their heads of bloom. The system throughout, in fact, is simply one of cool culture combined with late propagation, under which the plants usually attain about 1 foot high, while the heads of coloured leaves are in size proportionate. Plants of this size are decidedly more serviceable for decoration generally, whether employed in baskets or in a cut state. One great advantage of plants coolly grown is that they suffer less when used for decoration than those grown in much warmer structures. These latter are usually unnecessarily tall for many places and positions, and gardeners would do well to grow a batch of dwarf plants as a reserve for decoration generally. I am aware that the cool system is in vogue in private gardens and nurseries alike. Upwards of fifteen years since I saw a large number thus grown in a nobleman's garden in Hertfordshire, and quite recently in the nurseries of Messrs. Heath and Son, of Cheltenham, I saw 200 or 300 of these dwarf plants. Indeed, the Messrs. Heath, who are themselves large floral decorators, have made these dwarf plants quite a feature for years past, and during the past summer the plants were growing quite

exposed in the open, where they remain till cooler nights render it necessary to cover the plants with lights. These plants, notwithstanding the pots were quite 6 inches or 8 inches apart and the great heat experienced, carried foliage to the pots, a proof that they were quite happy under the treatment.

E. J.

**Swainsonia Veitchi.**—No one could scarcely pass this elegant plant when in flower without expressing admiration for it. It is a member of the Leguminosae, and the majority of the species have coloured flowers. In the plant under notice the flowers are exquisitely pure in their whiteness, and therefore very chaste and beautiful. When the plants are established and well grown, they are rarely to be seen without flowers upon them. The spikes of pure white blossom are enhanced in their value by the elegant foliage of the plant. It is one of those easily grown greenhouse subjects that thrives with but little care, and where large and cool conservatories exist, would form a capital subject for planting out. In such places its elegant foliage and pure white spikes of blossom would be much esteemed. Under pot culture the plant gives but little trouble, succeeding best in a mixture of peat and loam similar to that usually given to Genistas and such like plants. All the kinds may be readily increased at the

*Villarsia nymphæoides*, showing growth.

present time by cuttings inserted in sandy soil and covered by a bell-glass. Cuttings 3 inches or 4 inches long and with a heel attached are the best. By pinching the points of the shoots twice during the season, nice bushy plants result, and in this way a few specimens may be prepared for autumn flowering. In summer the older bushes may with advantage be planted in the open garden, where they would yield a useful supply of their pleasing and fragrant blossoms.—E. J.

**Aralia Veitchi.**—The slender-growing specimens seen at exhibitions in collections of table plants can hardly be identified with the vigorous-growing, large-leaved examples occasionally seen when planted out in suitable soil. I find it is also inclined to lose the very slender habit even when grown in pots. To have plants of a suitable size for table decoration it is necessary to propagate at least annually. Grafting seems to be the only safe method of keeping up a stock. *Aralia reticulata* is the best stock, and this is easily propagated from cuttings. The grafting may be done at almost any season of the year, though I find it is best not to do it during the very hottest weather. If the top of a fair-sized plant is taken off, the same plant will break out and give further stock later on, but it is very slow work to use anything but tops or the lower part of the stem after the lateral shoots have started. All of the slender-growing Aralias

should be potted in rather light peaty compost and good drainage should be given. Although usually grown in the stove, I have seen plants doing well in an ordinary greenhouse. Of course it would be fatal to take them from the stove and expose them to a low temperature all at once, but if gradually hardened off they will stand well where the thermometer does not fall much below 40° F., and will be more serviceable when required for table decoration or other purposes where they would have to be exposed. At most of the Chrysanthemum shows a class is provided for table plants, and in almost every successful collection one of the Aralias will be found.—H.

## GARDEN FLORA.

### PLATE 1036.

#### VILLARSIA NYMPHÆOIDES.

(WITH A COLOURED PLATE.\*)

THE round-leaved Buckbean is a very pretty little native aquatic plant, which is not uncommon in the reaches of the Thames from Richmond upwards. It is said to be truly wild only in the southern counties, although it is to be met with in the north, where, however, it has no doubt been introduced. It is plentiful in the moat between the old deer park at Richmond and the towing-path of the Thames, as many British botanists know, this being the source of a great many specimens in herbaria, the plant being one of those rare natives which are so dear to the collector. Mr. Moon's picture was prepared from plants that had been transferred from the park moat to the tank for aquatics at Kew, where also it is established in the lake.

Considering the beauty of the flowers and the ease with which the plant may be established in gardens, it is surprising that so little has been done with it horticulturally. In July, August, and September I have seen the moat at Richmond studded over with thousands of the bright yellow star-like flowers, making a picture fit for the choicest of water gardens. The roots grow in mud a foot or two below the surface of the water, producing slender branching stems with alternate leaves, and other floating stems upon which the leaves are opposite and which are terminated by a cluster of flowers. The leaves are like those of a *Nymphaea* in shape, but much smaller and thicker, and they generally have a few rust-red blotches on the upper surface. The stalks of the leaves are long or short according to the depth of the water. The flower-stems are erect, 1 inch to 3 inches long, each bearing a single flower an inch in diameter and formed of five spreading petals, which have thin crisp margins and are coloured bright yellow. The fruit matures freely, and good seeds may be obtained in late autumn.

Whilst some botanists call this plant by the name adopted here, others refer it to *Limnanthemum*, and it has also been placed with the Bogbean proper, under *Menyanthes*. It resembles *Limnanthemum* more than the other two, although there is a close family resem-

\* Drawn for THE GARDEN in the Royal Garden Kew, by H. G. Moon. Lithographed and printed Messrs. Joseph Mansell, Limited.

VILLARSIA NYMPHÆOIDES.

blance between the three of them. The distribution of the species here figured extends from West and Central Europe to China, the genus *Limnanthemum* being as widely distributed as is *Nymphaea*, viz., throughout the tropical and temperate zones. There are fourteen species, all aquatic in habit, some of them being much larger than our native species. For instance, *L. indicum*, common throughout India, has leaves 1 foot in diameter and whitish flowers; *L. Humboldtianum*, a South American species, has leaves 6 inches across and large, stellate, fringed flowers nearly 2 inches across, white, with a yellow eye; and *L. calthæfolium*, an Australian species, has spikes of flowers 7 feet or 8 feet high. So far as I know, none of these are in cultivation in Europe. Collectors might do worse than send home seeds of these and similar interesting ornamental aquatics, for it would seem as though the water garden is likely soon to receive much more attention in this country than it has yet done. W. W.

## THE WEEK'S WORK.

### KITCHEN GARDEN.

**JERUSALEM ARTICHOKE.**—As a rule, these are not in demand until a few sharp frosts have occurred, it being generally supposed that by the freezing the flavour is improved. Where required, however, they may now be lifted, the smaller tubers being laid in ashes or covered with leaf mould, to be used as seed in the spring. Artichokes retain their quality better if left in the ground and dug as required. The Chinese Artichoke (*Stachys tuberosa*) is a favourite with many, and should be lifted by the first week in November and stored in the same way as Beetroot.

**BEETROOT.**—The Turnip-rooted variety and the earliest sown rows of the long-rooted section should now be taken up, sorted, and removed to the root shed. It is a good plan to size them, keeping the large, coarser portion of the crop by itself for immediate use. The medium-sized roots are what are most appreciated for the salad bowl or for slicing up and serving cold. When lifting be careful not to injure the tap root, and when cleaning avoid scraping the skin, this causing bleeding. I do not advise cutting the tops off close to the crown, rather leave a fair length of leaf-stalk, and when storing arrange the roots in layers, with a layer of moist soil between. Where it is desirable to save roots of any choice strain for seed next year, the best plan is to select the required number of medium-sized, well-shaped roots and to clamp them in the same way as Potatoes, covering them with a good thickness of dry Bracken, and finally with soil, letting in a Seakale pot at the top of the clamp for the admission of air in mild weather. During frost the pot should be stopped up with Fern or straw. Where store-house room is short, every other row of roots may be lifted and the others earthed up with soil to protect them from frost. Unless very severe, they will take no harm, especially if a covering of litter is given during frost.

**ENDIVE.**—Attention must now be given to this important salad, as in all large establishments it will soon be preferred to Lettuce, at any rate as a change. When the delicate Moss-curved variety is grown for early use it should now be blanched, as much wet soon rots the centres. If a spare frame can be placed over the plants where they stand, they can be shielded from rain, and blanching accomplished by covering the lights with garden mats or even Bracken, admitting a little air by tilting at the back of the frame, but allowing the mats to fall down over the aperture. Where Lettuce has been scarce and no frames at hand, I have seen this early Endive quickly blanched in the border by laying some large light slates over the plants. The earliest and largest plants of the Broad-leaved

Batavian must now be lifted and placed in frames, or, better still, pits, as in the latter better drainage is secured and the plants are less liable to damp off in foggy weather. In the case of extra large spreading plants it is best to tie up the foliage before starting to lift, so as to prevent the soil from falling into the centres. Thrust the spade in on both sides of the plants and lift carefully so as to get as much soil with the balls as possible. Make a slight trench sufficiently deep to contain the roots and cover with soil from the next trench, pressing it firmly round each plant with the hands. Planting completed, give a gentle watering through a rose to settle the soil firmly, after which expose freely in fine weather, drawing up and tilting the lights during rainy periods. Allow plenty of room between the rows and individual plants, as a free circulation of air is essential to ward off damp and decay. Sometimes Endive is planted along the front of orchard houses, being first laid on the hard border and then covered with dry soil, receiving a good watering afterwards. Here, with the admission of plenty of front air, the plants winter well and are easily got at during hard or snowy weather. Sometimes plants resulting from a late sowing may be safely wintered at the foot of a warm south wall, being covered with dry leaves if frost necessitates it. I find Fraser's Improved Broad-leaved the best all-round Endive, and less liable to run to seed in spring. The flavour also is sweet and nutty.

**CABBAGES IN FRAMES.**—Small plants of August sowings of spring Cabbage should now be pricked out into frames with a view to protecting them through the winter. The smaller the plants the better, provided they have perfect centres and healthy roots. Brown Cos Lettuce should also be served in the same way, as the recent great heat induced a free and sappy growth, which would be easily injured by frost. Stir soot freely into the soil in the frames, as slugs are generally troublesome, and during wet weather draw the lights over the plants and sprinkle wood ashes over the surface, or damp and decay will be likely to work sad havoc.

**LIFTING HORN CARROTS.**—Although Carrots are not easily injured by frost, it is advisable to lift all crops of this root as they mature, so that the ground may be turned up. As there is always a percentage of the roots either cracked or deformed, it is well to separate these from the rest, as in the case of Beetroot. They can then be used for soup, the better-shaped roots being reserved for more important purposes. It is not imperative to give Carrots shed room, as they keep well enough if laid in soil, ashes, or sand behind north walls, where they can be covered with litter in case of very hard weather. The lifting at present will be confined to the Horn section, the intermediate and long varieties being best left in the ground for some time longer. If lifted too soon the roots shrivel early in spring. Late-sown beds of Carrots intended to afford young tender roots for soups in autumn and early winter, whether in frames or the open ground, must be kept quite free from weeds and rubbish.

**TURNIPS.**—Breadths of Chirk Castle sown for a supply during winter will now have swelled to a good size, and may be encouraged to become larger by one more broadcast sprinkling of guano or fish manure. Later sowings with bulbs only the size of Walnuts need frequent stirring with the Dutch hoe, as with a fair winter these roots will continue to grow till the new year, being then most useful, besides supplying tender tops. Any full-grown bulbs of Golden Ball should be lifted and laid in ashes in some convenient corner, as if left in the ground, splitting and decay are sure to follow.

**SALSAFY AND SCORZONERA.**—It is too soon yet to lift these, as healthy roots on good ground will grow for some time to come. Many early sown plants have this season owing to the drought run to seed, and many in successional batches are showing a tendency to do so. It is almost waste of time and ground to sow early, as in nine cases out of ten bolting ensues. It is not too late to

give another good soaking of farmyard liquid of good strength to increase the size of the roots, as thin, wiry roots possess very little flavour. The new Russian Scorzonera is a great improvement on the old variety.

**ROUTINE WORK.**—In many places copious rains have fallen of late. This will have produced a fresh colony of weeds amongst late-planted crops. As soon as a fine day favours it, the Dutch hoe and rake must be put through once more. The rake is necessary, as it is seldom that weeds simply hoed up die after this date, but grow away again after the first shower. Any rows of late Peas, Scarlet Runners, or Marrow growths should be cleared off without delay if only for appearance sake. Choose a fine day for giving another sprinkling of salt to the walks in the kitchen garden. J. CRAWFORD.

### FRUIT HOUSES.

**FIGS IN POTS.**—The earliest crop of Figs is best obtained from pot trees or those in restricted borders. Many have not room for permanent trees, and for hard forcing pot plants are always reliable, given good culture. Now is a suitable time to prepare pot trees, repotting, cleansing, and doing any necessary pruning. There will, however, be little pruning if due attention was paid to stopping and ripening of the young wood. The fruit produced on the ends of the new wood is of better quality than on other parts of the tree. In the case of plants which are large enough it is well to shake them out of the pots, removing a few inches of the old ball with a pointed stick and cutting back the large roots, replacing in the same sized pot and ramming firmly as the new compost is added. By reducing the ball, say, a couple of inches all round and cutting away a portion from the base, the trees will remain in good condition for two or three years. Larger trees that cannot be given a shift should be top-dressed with good material, such as turfy loam, with a liberal addition of bone-meal, old mortar rubble, and wood ashes if the loam is heavy. This builds up a sturdy, fruitful growth and short-jointed wood. Previous to top-dressing, the old ball of soil should be examined, and if at all dry well saturated before the new soil is added. After repotting it is advisable to place the trees under cover to prevent the new soil becoming soddened, but the plants should be kept as cool as possible, a thorough watering being given to settle the soil. Pot trees are less liable to insect pests than permanent ones, brown scale and mealy bug being the worst pests to deal with. In noting the value of small trees for a first crop, it may not be out of place to name the newer kinds valuable for hard forcing. St. John's and Pingo de Mel are invaluable, as they do not cast their first crop like some of the older kinds, and are wonderfully prolific. Though the fruits are not so large as those of Brown Turkey, they are above medium size and of good quality.

**YOUNG FIG TREES.**—Now is a good time to make a selection for pot work, as it is well to grow on a few young trees to take the place of worn-out ones. Excellent trees for fruiting next season may now be purchased in 6-inch or 8-inch pots to grow on. It is advisable to select those plants with a single stem and as short-jointed as possible, thus securing a good foundation for future crops. Cuttings struck last season should now be in condition to pot up into 8-inch pots or even larger if they have been well attended to during the first season of growth. I prefer shifting now before the plants have cast all their leaves, plunging the pots in ashes and sheltering from heavy rains. A cold frame or fruit house at rest is a good place to stand the plants in till started early in the year. Plants required for walls or planting out need different treatment. These should be pruned so as to secure good leaders for training and should be kept free of sucker growth. Any large enough to plant need not be potted on.

**PERMANENT FIG TREES.**—These will be under two headings, those which provide fruit in May

and those which give a succession. I will take the earlier first. The leaves of these should now have fallen, and it will readily be seen what pruning is required. I am a great advocate for early pruning, as a longer season of rest is secured, cleansing is facilitated, and any necessary repairs, painting and linewashing may be proceeded with. In pruning vigorous trees endeavour to lay in what is termed fruiting wood, that is clean, firm shoots, not at all soft or green. Cut out all useless wood from the base, avoid crowding, and do not allow sucker growth to rob the fruiting wood. It will readily be seen what is termed healthy fruiting wood—the points of the shoots of the new wood on this season's growth bristling with embryo fruits. These must get the best place and ample space to develop. After pruning, cleansing, and regulating the new wood, top-dressing may be done, removing the old surface soil down to the small fibrous roots and giving new turfy loam to which a liberal quantity of bone-meal has been added.

LATER TREES which gave the supply well into September will continue to produce small fruits of the second crop if allowed to do so. The grower's aim should now be to thoroughly ripen the wood. Remove these late fruits and cut away all soft and useless wood. If the trees were well attended to in the way of moisture and mulching, they will not require water at this season for a time. Should the top growth be late, it is well to give a little fire-heat during the day with a free circulation of air. Trees that do not bear freely and need root-pruning should now be attended to. Give such trees a good layer of brick rubble under the roots with plenty of good loam well rammed, using mortar rubble or wood ashes to induce sturdy growth.

CLEANSING FIG TREES.—Now is the time to clear away any insect pests. By cutting away the old wood it is an easy matter to cleanse the new. Care is necessary, as the new wood is often covered with small embryo fruits, which should be preserved. Washing the wood with strong soapy water with a very soft brush will eradicate scale. It is advisable to paint the wood after the cleansing. The wood should be painted with a mixture of sulphur, soft soap, and clay, with a wineglassful of tar to a gallon of mixture for trees badly infested with bug, well rubbing in the mixture on the old bark. Omit the tar when dressing the young growths.

LATE MELONS.—The season for late Melons has been more favourable than usual, and the fruits so far have finished well. With a sudden fall in the temperature the grower will find a difficulty in getting good flavour unless there is plenty of top and bottom heat at command. For late work I advised pots, as the roots can be better managed as regards moisture and feeding. Very late fruits will need the latter to get quick growth. A liberal temperature must be given, as sudden changes will cause damping at the collar and collapse of the plants. There will be few superfluous growths on pot plants. Trees with more root space should not be allowed to make too much growth. Very little air will be required, and damping down should be done soon after mid-day. A night temperature of 70 must be given fruit finishing, the thermometer being allowed to run up freely during the day. The fruits as they ripen should be detached from the plants and finished on a warm shelf.

STRAWBERRIES IN POTS.—The plants will now be maturing the summer growth, and, with heavy rains, need care to prevent waterlogging. It is also well to move the plants frequently to prevent rooting through, and to turn them round to get them hardened. Runners will form freely; these need constant removal, and, though rather late, it is advisable to keep the side growths which form close to the main crowns removed. This, if done frequently, assists the crowns to swell up. Care must be taken that the plants do not get dry. I like to keep the plants as long as possible in the open if due attention is paid to moisture.

G. WYTHES.

## ORCHARD AND FRUIT GARDEN.

### CRYSTAL PALACE FRUIT SHOW.

TO THE EDITOR OF THE GARDEN.

STR.—As a country visitor to the great fruit show recently held at the Crystal Palace, and as one taking an active interest in the management of a fairly good provincial show, I was quite taken by surprise at the lack of arrangement for staging the various exhibits. We look for slipshod work in shows managed by inexperienced amateurs, as they frequently are in places where social status goes for more than practical ability, when arranging the committees, but when visiting a great metropolitan show held under the auspices of the Royal Horticultural Society we have a right to expect that the arrangements shall be as nearly as possible perfect. But what was the fact? I found the greatest difficulty in locating the exhibits in the various classes, as in some cases exhibits in the same class would be found on different tables and perhaps at a long distance apart, while on the table or space which would seem to have been set apart for one class, exhibits in another had found a place. This was particularly noticeable in the class for six bunches of Grapes; one exhibit was missing from the table which held the others, and space which it might have occupied was filled by Grapes from another class. If this want of arrangement only affected members of the general public, there might be no cause for more than the grumble to which all Englishmen are entitled; but it is a fact that two exhibits, one of the twelve bunches of Grapes and the other of the six bunches, were completely overlooked by the judges until their attention had been called to the matter some time after the prizes had been awarded. In each case the exhibit was awarded a prize, which, but for persistence in looking up the judges, would have been lost to the exhibitor. It was the opinion of many good judges that one of these exhibits ought to have been placed at the top of its class. Surely arrangements which allowed of an exhibit of twelve fine bunches of Grapes being missed by the judges will bear some improvement, and the pity of it is that a retrograde step must have been taken, for in the old days when the admirable methods contained in the "Field Judging Book" formed the basis on which the judging at R.H.S. shows was carried out, such an oversight would have been next to impossible if the judges took the most ordinary care in carrying out their work.

In my opinion the diamond-shaped tables were a mistake in such a place as the Crystal Palace, where there is ample room for broad gangways between tables of the ordinary form. The little attempts to break up the line of sight were paltry in such an immense building and with surroundings so massive; they added nothing to and probably took something from the general effect, while they certainly helped to confuse exhibitors, judges, pressmen, and those members of the general public who wished to make notes. It is a positive injustice to exhibitors not to allow their exhibits space side by side with others in the same class, for judging cannot be well carried out under any other conditions, and if by any chance exhibits are overlooked, judges, being only human, do not care to alter their awards even when such mistakes are discovered in time to allow of alteration, while exhibitors who may have to take lower positions than those originally awarded may be forgiven for indulging in unpleasant remarks anent the whole business. Such a

jumbling method of exhibiting the grand fruits that were brought to the Crystal Palace for this show ought to be beneath the R.H.S., and should never be repeated.—CORNUBIAN.

—The recent splendid show held under the auspices of the Royal Horticultural Society will doubtless become an annual one, but it will certainly need some revision before it commands respect from exhibitors. It is no easy matter for an exhibitor to travel a long distance, probably been up all night, and when he gets to the show to be bandied about from pillar to post, told to stage here, move there, and then have to move everything when he has set up his exhibits, owing to the space being required because, I suppose, more entries have come than room was allowed for. I protest most strongly against this haphazard staging. For instance, if there is not room, half a class or a portion is staged a considerable distance from the other. This is unfair to the exhibitors, to the judges and the visitors, and to those who wish to compare notes. Part of the class is never seen at all, and the exhibitor is not only worried at a time he needs a cool head, but does not get justice, the judges being unable (in some cases) to find the fruit. In others it is so crammed, that comparison is out of the question. Why cannot the Chiswick or Kensington method be followed, beginning at class 1 and following with each class as far as possible? I admit it may be necessary to have a prominent exhibit, like Grapes, in the centre, but that would be a simple matter, and the schedule could be followed throughout from, say, class 24 to 128; whereas a portion is wedged in here, another there, and there is confusion. Doubtless the judges in some of the classes will be strongly condemned for the errors of judgment. Take Grapes, for instance. Some staged were not seen when the class was first judged, the judges having to go over the exhibits again. The judges in this case could not be blamed. The exhibitor, who fortunately was present, looked after his own interests. I find assistants who dare to complain get scant attention, and it often happens young men are sent with exhibits. Of course I cannot justify the judges who gave the first prize to the wrong variety. This occurred also last year, and points out the necessity of the judges in each class being experts. Again, reversing the awards after the classes have been judged some hours is annoying to those who exhibit and is the cause of severe criticism. I admit trade exhibits can make a show, but there is a healthy sort of horticulture in competition, and exhibitors should be encouraged. Another point needing attention is the so-called gardeners' luncheon. Why not have a popular lunch near the exhibition? The last one was in a vast room at the extreme end of the grounds, needing a long journey to tired exhibitors on a melting hot day. The society, which is so anxious for reforms, will doubtless favourably consider my appeal on behalf of the poor exhibitor.—AN EXHIBITOR.

—Visitors to this show were no doubt much struck by the many fine dishes of Apples and Pears that were staged and admired their colour and finish, but how many of those kinds are really useful from Christmas onward many practical growers were asking themselves. For cooking Apples there were, in addition to those for collections, thirty-two classes, the greater portion of which consisted of early and soft-fleshed varieties, such as Bismarek, Cellini, Cox's Pomona, Duchess of Oldenburg, Ecklinville, Emperor Alexander, Lord Derby, Lord Grosvenor, Lord Suffield, Peasgood's Nonsuch, Potts' Seedling, Stirling Castle, Loddington, The Queen, Grenadier, New Hawthornden, Warner's King, and Gascoigne's Scarlet. I do not know who is responsible for the schedule, but certainly more attention ought to be paid to encouraging the growth of late kinds instead of those that only flood the market during September and October. As an illustration, let us take the variety Wellington, Dumelow's Seedling as some call it, the latter name being the one it was shown under at the Palace. In this class

there were twenty dishes staged, and when I complained of the first prize being awarded to a dish of New Hawthornden the cards were changed, but not till after the reporters had been round. The third prize, however, was withheld. This does not say much for the ability of the judges employed or the fairness of the authorities of the R.H.S. Again, in the class for Bramley's Seedling I failed to find the dish on which the first prize card had been placed, and many others were the same. True, most of those varieties named above are good show kinds, and did every credit to the cultivators who staged them, being very attractive on the show table on account of their colour and finish, but where should we be if fruit was simply grown for exhibition and all such kinds as were not showy discarded from our gardens? If those responsible for compiling the schedule had to supply the kitchen from January onward, they would be sadly wanting if only those mentioned above were grown. Why should not such sterling varieties as Yorkshire Greening, Norfolk Beaufin, Hanwell Souring, Royal Russet, Easter Pippin, Queening, and many others of like excellence find favour? Gardeners who have to supply the kitchen know full well the value of these long-keeping kinds, and on that account usually plant them in preference to more showy kinds.

Turning to the dessert kinds, we here find Worcestershire Pearmain, which is far inferior to the old Keswick Codlin, with a class to itself, while such grand varieties as Court Pendu Plat, Court of Wick, and Sturmer Pippin are left out. The first idea that would strike a practical gardener when looking over the schedule would be that it was either compiled by nurserymen who have those varieties of trees to sell, or by some interested party who has only a superficial knowledge of what is really required to supply a gentleman's establishment or our own markets.

Let us now turn to Pears, and here again we find the same blunders, prizes being offered for worthless kinds, while really good well-flavoured varieties are altogether ignored. One would have thought that a society like the R.H.S. would have set an example by encouraging the production of really first-class fruit, instead of which they do not seem to know what a really good Pear is, for many of the classes in their schedule were allotted to varieties of very inferior quality simply because they grow to an extra ugly size. Who cares for Souvenir du Congrès, Pitmaston Duchess, Maréchal de la Cour, or even for Beurré Diel? Such, no doubt, look well on the show table and in the shop window, but as dessert varieties they are certainly very inferior, and are not worthy to be compared with Gansel's Bergamot, Hayshe's Prince Consort, White Doyenné, Passe Colmar, Jean de Witte, Seckle, Thompson's, Hacon's Incomparable, Van Mons Leon Leclere, or Zephirin Grégoire. Most gardeners know that soil and situation alter both the flavour and the appearance of Pears wonderfully. The latter kinds are, however, usually of the finest quality, and may be relied upon as being suited to most soils and climate, as I have found by experience from cultivation both in north and south. Here, too, the greater number of classes was for early varieties, while but few were allotted to the late kinds. If we are to have an R.H.S. worthy of the name, it should certainly take a leading place in horticulture instead of being in the background.—H. C. PRINSEP, *Buxted Park, Uckfield.*

**Apple Cox's Orange Pippin.**—Surely this has been a record year for this famous Apple, as never have I seen such crops of it. It is hard to believe that this Apple refuses to fruit in some gardens, yet we must admit this from what we so often read in the horticultural press from time to time. During the last few weeks I have seen many standards of it, and in all cases the trees were carrying grand crops of fruit. In the orchard here one half-standard tree sixteen years planted gave us this season six bushels of highly-coloured fruit. The soil is somewhat heavy and retentive of moisture, yet there are but slight

signs of canker or any other disease about the trees. In the orchard attached to Mr. Perkins' garden near Southampton there are at least thirty large trees of this Apple. The soil there is somewhat thin, resting upon gravel. As standards, bushes and cordon-trained trees as edgings to paths they are grown. In no case was there a failure to crop and the colour was remarkable. More than one fruit I measured was over 10 inches in circumference. In Mr. Peters' fruit garden at Nutbourne, near Em-worth, not far from the sea, where forty acres are devoted to fruit culture, Cox's Orange Pippin is held in the same esteem. The trees mainly are freely grown bushes, and at the time of my visit the branches were literally loaded with fruits of excellent quality.—E. M., *Swanmore Park, Bishop's Waltham.*

— This Apple is fruiting in this neighbourhood on half-standard trees with greater freedom than it has done for many years. Why this should be is not easy to say, as last autumn was anything but the best for consolidating growth. The majority of the trees of Cox's Orange in South Notts generally fail to fruit, not because there is no bloom, but because this falls to the ground instead of setting, it being very tender. A nurseryman told me some time ago that the delicacy of its bloom was its greatest drawback. I have it growing in various aspects as an espalier, but it fruits but very sparingly, although annually laden with blossom. I think with Mr. Molyneux that it does best grown in a loose, untrammelled form, the leading shoots being shortened but little, but the weaker spray entirely removed. Doubtless Cox's Orange Pippin is a capricious Apple, except in the most favoured soils and climates. In Essex I have seen healthy trees go barren year after year, and in a recent tour in Norfolk I did not once meet with a tree bearing a good crop.—J. C., *Newark.*

— This must be a record year for good quality in what may be termed the best Apples. The fruits of Cox's Orange this season are finer than usual. At the recent Palace show there were no less than forty nine dishes in the single dish class. Cox's Orange appeared to me to be the most popular Apple in the building, and the dishes staged by Messrs. Turton and Wright showed to what perfection this Apple could be grown. I will remember how well this variety did in standard form in Hereford and Monmouthshire many years ago. So far, we have no dessert variety to equal it, and its free cropping makes it doubly valuable. I fear with so much heat during the last few weeks it will be impossible to leave this variety on the trees as late as one could wish, and the season will not be a long one. It is well to store late to secure good fruits during the first three months of the year, as when gathered late they do not shrivel so quickly if kept very cool.—G. W.

**Late Apples.**—The value of these will become more and more apparent if we continue to have dry summers and hot, sunny autumns, as under these conditions not only do all our early Codlins ripen too speedily and soon become useless, but mid-season sorts also quickly follow on and are past long before they ought to be, a glut taking place in November. This is not only a drawback in private places, but a serious loss to those who grow for market. I think that if those who contemplate planting in the future were to include many more trees of later varieties than is usually done, better and more profitable results would follow, as many of the late-keeping Apples are fit for use in December. I cannot help thinking, too, that some of the very old sorts which seem to be elbowed almost out of cultivation would still pay well to grow. What better Apple is there for flavour than the old Sturmer Pippin, or for cropping either, although it is but of medium size? For pies and sauce I know of none to beat it. Hambleton Deux Ans is another excellent old and almost discarded Apple. I saw it in Lincolnshire two years ago in grand form on old standard trees, and it was the sheet anchor of the fruit room in February and March. Both these Apples carry with them a good amount of natural sugar.

Rymer, again, another very old cooking Apple, will carry on the supply even longer, and although slightly acid, is delicious when cooked and sufficient sugar added. This sort used to be grown in Essex many years ago, but I had lost sight of it until last month, when I saw it at Blickling Hall, Mr. Oolee, who evidently knows its value, having planted it in a good position. One of the very best Apples to grow in order to prevent a break in the supply between the earliest varieties and those above-named is Earl Morrin. It is fit for use in October and will keep sound till February.—J. C.

**Alpine Strawberries.**—These are pleasing and almost showy from the number and brightness of their variously-shaped fruits, some being round and others egg, almond, and pyramid-shaped, and in all cases the fruits are fairly large and the green calyces more so proportionately. It is largely due to the dressy calyx and the way in which the bright red fruits are held up by the ascending, yet slender stalks that these plants attract notice so late in the year. However, one could do worse than plant these Strawberries for effect in the rock garden; their only fault for such purpose is the way they wander.—J. Wood.

**Open-air Peaches.**—I quite agree with "J. C." (p. 255) that Peach-growing against open walls is on the increase. In very few instances will the theory hold good that unsuitable seasons and positions are not favourable to open-air Peach culture. I have lately seen excellent crops upon trees growing in town gardens where the air is admittedly not so favourable as that in the country. According to my experience Peaches will fruit successfully not only on south, but also on east and west walls; indeed, it is an advantage to have trees growing against walls with a western aspect, the season of ripe fruit being much prolonged in consequence.—E. M.

**Apple Bramley's Seedling.**—I cannot say, like "G. W." (p. 255), that this Apple bears freely in a young state. In the autumn of 1891 I planted one hundred maiden trees; these were cut tolerably hard back to induce them to break vigorously near the base. Although they have grown well, I have had no fruit from them. I think they will bear freely when established and are making less vigorous growth. In the autumn of 1890 I planted fifty standards; these have grown freely and most of the trees bore a good crop of fruit this season.—E. M.

**Small Pears.**—I would like to supplement Mr. Prinsep's remarks on small Pears, page 234. Doubtless, as he contends, many of them are of much finer flavour than the larger kinds, to say nothing of their more suitable size for the individual guest at the dining table. Several of the sorts, however, mentioned by Mr. Prinsep are suitable only for the best of soils and climates. With me Winter Nelis grows and fruits remarkably well both on east and west walls, the soil being light and well drained, but Ne Plus Meuris on a sunny wall was never even in the best of summers fit for anything but stewing, so I discarded it. I do not think this Pear will ripen out of doors either in midland or northern counties. I have grafted it with Beurré Rance, a much more reliable variety, and, I think, still unsurpassed as a late Pear. Comte de Lamy is not so well known as it should be, as it is a certain bearer, is not particular as to soil or aspect, and being very sweet and refreshing, yet not over-rich, is just the Pear for invalids. This little Pear does well in Norfolk. Aston Town, also mentioned by Mr. Prinsep, was grown here on a wall, but although the wood was clean and healthy and the tree not too vigorous, it never bore a single fruit, and was, after years of patient waiting, rooted out. I have been informed by a gentleman acquainted with its origin that it is very capricious, although when well ripened most delicious. Thompson's cannot be surpassed for richness, and succeeds well on our light, well-drained soil, but cankers badly a few miles away planted in strong loam. A cool season suits it best, as in a hot one

like the present it not only ripens weeks before its proper time, but is mealy also. Some years ago when our summers were more moist and cool, Thompson's did not ripen until December, but for the past few seasons it has been fit for eating in October. I have it on an east, also a west wall, but on neither will it stand a dry season. One of the very best of the small Pears, and which will moreover keep sound for a month when fully ripe, is *Beurré d'Aremberg*. It crops enormously whether on wall or espalier, coming into use in December. That old Pear *Beurré de Capiaumont* is not so often met with as formerly, although it is a constant bearer, and the crisp, juicy fruit is liked by most people.—J. C.

**Princess Pear.**—This Pear is very good this season, showing that it likes a warm soil and plenty of sunshine. It is a seedling from that excellent variety *Louise Bonne* of Jersey. Princess promises well both as regards cropping and good flavour; the flesh is soft and melting, and it is a very handsome fruit. I have it very good this season on a warm wall. Like many other varieties, it will be fit for use long before its stated season (November). The fruits at this date (the end of September) are colouring up freely. In future I intend to grow this variety in bush form on the Quince stock, and by this means get a succession to *Louise Bonne* of Jersey. The fruit when well grown is of a nice size—in fact, it much resembles that of its parent in size and shape, being long, pyriform, and of a pale yellow flushed with red.—S. H. B.

**Pear Beurre Diel.**—How well this variety has fruited this season. The fruits are larger than usual, and in my case quite free of the russet markings usually seen. The best fruits are on a warm wall with a south-west aspect. The stock is the Quince and the fruits are very fine, showing how well a hot season suits such varieties and the value of a warm soil. It will be interesting later on to test these very fine fruits and note if the flavour is superior this year, as with good finish there should be superior flavour and freedom from the grittiness this Pear is often subject to. I have this variety on the Pear stock in pyramid form, and the fruits are not at all good either in shape or size and always gritty, though well attended to, showing that this variety in cold or exposed districts and in heavy soil should be given wall culture.—G. WYTHES.

**Plum Reine Claude de Bayay.**—The brilliant sunshine of the past few weeks, coupled with the high temperature, has rendered this late Plum of most excellent quality, this being quite different from its behaviour in the ordinary run of seasons. The flesh with me has, as a rule, been stringy and of poor flavour. Whatever may be its quality in a better climate and on a warmer soil I do not know, but if we could rely upon it in the ordinary run of seasons to ripen as well as this year, it would be one of our most valuable Plums, ripening, as it does, so late as the last week of September and the first week of October.—A. YOUNG.

**Red spider on Vines.**—Whilst holding to the opinion that in very bad cases of attacks of red spider exceptional remedies may be necessary, I certainly have faith in retaining the old bark on Vine rods, believing that the Vines are benefited thereby. During the past nine or ten years I have not had any taken from the Vines under my charge, and if the same winter treatment is accorded in the future as in the past, they may go on for as many more. The winter washing cannot be too thorough or enough care taken. In many cases the washing the Vines undergo is more a matter of form, that is, the wash is not made to soak deep enough. The best plan I find is directly after the leaves have fallen and the Vines are pruned to give the rods a thorough washing with warm soapy water, working it well in with a new painter's brush, afterwards before the rods become dry following on with an application of Gihurst compound. I daresay in cases where the Vines have been very badly attacked more drastic measures need to be taken, but otherwise I think the above course of treatment is ample,

and if persisted in annually, red spider may be prevented from remaining on the Vines during the winter.—A. YOUNG.

## ORCHIDS.

### CYPRIPEDIUM SPICERIANUM.

WITH the opening days of October came the first flowers of this distinct and handsome species, and where sufficient plants are grown and brought on successively they will continue in beauty until the new year, the individual flowers lasting in many cases for four or five weeks. When first introduced, *C. Spicerianum* was very expensive, but, as is usual when the habitat of any Orchid is discovered, further importations soon brought down the price, and as it is now to be obtained for a few shillings and is seen in nearly all collections, it may be included amongst the most popular in this very extensive genus. It was named in compliment

to the genus, it requires an abundant supply of water at the roots, and in making up the compost this must be taken into consideration and provided for accordingly. The best mixture I have tried consists of three parts of nice mellow, but fibrous loam with some of the soil shaken out from the fibre, the remaining portion being made up of peat similarly treated and fresh chopped Sphagnum Moss. Some growers leave out the latter altogether and depend wholly upon loam, but the Moss gives greater elasticity to the bulk and prevents it settling into a close and heavy mass. Some rough pieces of crocks or ballast should be mixed with this, or even preferably introduced as the work of repotting is in progress. The plants if healthy and in good condition at the roots should be disturbed as little as possible when repotting, just breaking the pot with a hammer if they are clinging to the sides and spreading them out well in the new pot, filling in with the compost to within an inch or so of the rim. If, on the other hand, they are found to be decayed and the old compost sour, it will be better to well

*Cypripedium Spicerianum.*

to Mr. H. Spicer, of Godalming, and comes from India, whence it was introduced in 1878. In habit, *C. Spicerianum* somewhat resembles the old *C. insigne*, but the undersides of the leaves, which are rather broader than those of the latter, are spotted with deep purple. It is a free grower, and under suitable conditions small pieces soon make good plants that flower freely at the proper season. The scapes are usually one-flowered, though when the plants are in vigorous health twin-flowered scapes are not uncommon. The dorsal sepal is from 2 in. to 3 in. long, pure white at the apex, with a deep purple line running down the centre and tinged at the base with green; the petals are 2 inches in length, wavy, light green with spots of purple, and the lip is broad and deep purplish brown. This represents a good typical form, but many variations will be found in a large number of plants both in size and colour. *C. Spicerianum* is very easily grown, and is not fastidious as to temperature. A brisk heat while making its growth suits it best, the leaves being larger and the flowers more freely produced than in a cooler house. Like all in

wash the roots in warm water, swilling away the whole of the grit from about them and cutting away all dead parts. This is a state that *Cypripediums* take a long time to recover from, and very careful treatment is necessary to bring them round. The compost for such may be made a little lighter by the addition of more Moss and crocks, and the plants must be put into as small pots as possible. The drainage in each case must be thorough and well protected until the roots again get a hold of the compost. After potting, the plants must be put at once into heat and encouraged to grow strongly, watering freely as soon as the roots commence running among the soil. Towards the end of the summer the flower-buds will make their appearance, and if it is intended to keep up a succession, some of the last to show bloom should be retarded by placing in a slightly lower temperature, or by growing some of the plants a few degrees cooler the same end is attained. As soon as the blossoms are fully open the plants must be taken to a drier atmosphere in order to preserve them as long as possible. When they are over they may be kept as quiet

as possible until the end of January or early in February, and this will be the best season to report any that require it. R.

**Oncidium Lanceanum.**—This has flowered twice this season, and the last of the blossoms are just going off. The chief attraction of *O. Lanceanum* is the rich contrast formed by the rosy violet shade of the curiously shaped lip with the deep chocolate spots on the sepals. The present season has been all that could be desired for this plant, the long-continued sunshine hardening and ripening up the foliage, which is larger and more healthy looking than usual. I grow it in moderately large baskets in a compost consisting largely of Sphagnum and charcoal, and find that it dislikes being disturbed. A clear light is of the utmost importance, and for this reason it is kept as near the roof glass as possible, and from now until the growth commences in early spring the plants will be kept nearly dry at the roots.—H.

**Oncidium divaricatum.**—The blossoms of this *Oncidium* are individually small, but they are produced in considerable numbers upon the large branching panicles. The flowers are bright yellow with reddish brown spots about the base of the sepals, petals, and lip. The plant is of easy culture and very free flowering. It should be grown in the Cattleya house in the ordinary peat and Moss mixture, keeping the pseudo-bulbs well above the rims of the pots. This plant usually commences to grow early in the season, and takes a long time to mature its pseudo-bulbs. These produce flowers at once, and the spikes if cut off when the flowers are newly opened often throw out small side branches, which are very useful for button-holes or sprays. It requires plenty of water while growing, but during winter it must be kept well on the dry side to induce the plants to rest until spring, this treatment being most likely to cause them to flower freely.

**Odontoglossum grande superbum.**—This is a fine form of the type, with very richly-coloured flowers of great substance. The varnished appearance usual in the species seems brighter and even more glossy than in the type and the sepals more brightly spotted. The lip is pure white in ground colour, with a few brownish spots. I have not seen more than four flowers upon a spike of this variety, while in the type from seven to nine are not uncommon. This, however, possibly arises from the fact that my plant is not very strong, though quite healthy and thriving.—H. R.

**Maxillaria picta.**—This old species is not large enough to find much favour in collections, but it is, nevertheless, a free-blooming and effective little Orchid. The flowers, produced on single-flowered scapes from the base of the bulbs, are each about 1½ inches across, bright yellow with crimson spots, the lip being almost wholly white. It is an easily-grown kind, thriving well in a cool house and requiring a fair amount of atmospheric and root moisture all the year round. It is best grown in small pots in peat and Moss. It is a native of Brazil and was introduced about 1830.

**Houlletia Brocklehurstiana.**—This is by no means a common Orchid, and it is a pity that it and the other species in the genus are not more grown, for they are really effective when in flower. The blossoms, moreover, are produced at such a dull season, that they are all the more welcome. The pseudo-bulbs of *H. Brocklehurstiana* are roundish ovate, and each bears one leaf a foot or more in length. From the base of these the spikes are produced, and bear many flowers which are brownish purple in colour, with many spots of brighter purple about the base of the sepals and petals. The lip is also spotted, but yellow at the base and bears on each side a peculiar horn-like process. Its culture is not difficult, the plants thriving well in pots or baskets in a free and open compost consisting of three parts of peat to one of Sphagnum, with a few pieces of charcoal or crocks. The plants like plenty of water at the

roots while growing, and the atmosphere must also be kept very moist. The Sphagnum may with advantage be allowed to grow freely about the pseudo-bulbs in summer, but a little of this may be clipped off during the winter. This *Houlletia* thrives best in the warmest and shadiest part of the *Odontoglossum* house, and the foliage must be kept free of thrips and red spider. It is a native of Brazil, from whence it was introduced in 1841.

**Lælia autumnalis atro-rubens.**—This is a charming variety, one of the richest in colour of this favourite species. The growth and flower-spikes are very vigorous, the individual blooms being large and well formed. The sepals and petals are of a deep, but brilliant crimson at the tips, becoming much paler at the base. The lip has an intensely deep blotch of purplish crimson on the front lobe, the side lobes being creamy white, lightly spotted on the upper edges. This has flowered with me earlier than usual, possibly on account of the amount of sun during last month. It thrives well on rafts hung up near the light at the cool end of the Cattleya house, and during its season of growth requires plenty of water at the roots.—H. R.

#### CALANTHE VERATRIFOLIA.

THE evergreen section of *Calanthes* to which this species belongs does not receive so much attention as do the deciduous species, such as *vestita* and its allies, nor can they be expected to rank so high in a gardener's estimation as these free-blooming and very useful plants. Still, they have many good points, not the least of these being the fact that they are very easily grown in an ordinary plant stove, and welcome additions to the flowering plants therein at this season. *C. veratrifolia* is as popular as any, and may occasionally be seen in capital condition where few or no other Orchids are grown. The foliage is large, giving the plants a very striking appearance whether in or out of flower, and the bloom spikes are upwards of 2 feet in length, bearing on the top a dense mass of flowers individually small and pure white. These last a considerable time in good condition if they are kept perfectly dry, but the least drop of water soon spots and disfigures them. It requires a moist heat while growing and abundance of water at the roots, and even when resting the soil about them must never be dry. It may be repotted in spring in a mixture consisting of fibrous loam, chopped Sphagnum, and well-rotted cow manure, adding some finely broken crocks to keep the mixture open. The pots should be rather large, so as to serve the plants for a couple or three years. The drainage must about half fill the pots, in large ones inverting a small pot over the drainage hole and filling up around it with the potsherds, finishing off with small bits and a good layer of rough Moss. This will make it impossible for the soil to be swilled down among the drainage before the roots get a good hold of the compost, after which there is no fear. The growth is usually rapidly made, and during the time this is going on a little weak manure water may be given at intervals of a week, or the plants may be lightly surface-dressed with one of the many good fertilisers now advertised. These greatly assist the growth, making it strong and vigorous, and the effect will subsequently be seen in large, healthy flower-spikes. If propagation is desired, the best plan is to cut through between the growths with a sharp knife some time before the division is to be made, endeavouring to secure as many roots as possible on each piece. The young shoots that spring up from the base may also sometimes be taken off and separately potted without interfering with the rest of the plant. The former plan is, I find, much the safer. As a great deal of the beauty of a plant of this kind depends upon the foliage, care must be taken that insects are not allowed to get the upper hand. Scale and red spider are the chief enemies, the former being more troublesome just as the new leaves are form-

ing, and the sponge must be frequently used to keep them under. A few variations from the type are recorded, the principal being *C. v. Regneri*, a form with a bright yellow lip, and one or two others. It is an old plant in collections, and widely distributed in Southern Asia and the islands of Australasia.

**Odontoglossum maxillare.**—Although fifty years have passed since this species first came into cultivation, it still remains amongst the rarest species of *Odontoglossum*. It is a native of Mexico, but the original plant described by Lindley in 1847 was a waif of whose origin nothing certain was then known. It was found by Roezli in 1872 on the Sierra Madre, in Mexico, and was re-named *O. madrense* after that locality by Reichenbach. It is under this latter name that the species is still most frequently grown. It is a handsome and distinct *Odontoglossum*, with thin two-edged pseudo-bulbs that measure 4 inches to 5 inches in height, and carry a pair of leaves 6 inches to 8 inches long. The flowers are borne on erect racemes, six or eight of them to each. In diameter they are each about 3 inches, the sharply-pointed sepals being white, marked with a blotch of reddish purple at the base; the petals are larger and broader, similar in colour, but with a larger blotch. The lip is shorter and broader than either the sepals or petals; it also is white, the disc and crest, however, being orange-yellow. The species has recently been in flower at Kew, and is well worth a place among autumn-flowering *Odontoglossos*.

**Pleione lagenaria.**—None of our cool Orchids do more to brighten up the Orchid houses in autumn than the *Pleiones*. Of the four or five species at present in cultivation *P. lagenaria* is the earliest to flower, and it is at least as beautiful and free-flowering as any other species. When well grown it is not unusual to see the whole surface of the pans or pots in which the bulbs are completely hidden by the profusion of flowers. This species has the short flat pseudo-bulbs characteristic of the *Pleiones*. They are about 2 inches high and of a dark, dull green with brown mottlings. The scapes on strong healthy plants are mostly twin-flowered, one scape being produced from each of the two or three young growths which are already pushing from the base of the pseudo-bulb. Four to six flowers may, therefore, spring from one pseudo-bulb, and as they each measure 3 inches to 4 inches across the sepals and are of a bright rosy lilac, it may readily be conceived that a few panicles make quite a brilliant show just as the dull days of early winter are setting in. The plants are destitute of foliage at the flowering season, this character and the dwarf habit of the species having suggested the popular name of Indian Crocuses. A few Maiden-hair Ferns and other light fine-foliaged plants should be associated with them when in bloom. The lip has a pale lilac ground, quite ornately blotched with yellow and crimson. This and all the *Pleiones* are natives of Northern India.

**Dendrobium formosum var. giganteum.**—This is certainly one of the finest *Dendrobies* in bloom at this season, the flowers, indeed, being individually amongst the very largest in this genus. When, as is the case with some of the stronger growths, eight flowers are borne at the apex of a single stem and each one measures from 4 inches to 5 inches in diameter, a large plant of this variety produces an effect not equalled by any other white flowered *Dendrobium*. The sepals are comparatively narrow, but the petals are broad and full (frequently 2 inches or over in width); both sepals and petals are of a pure glistening white. The large spreading lip is also white, but has a large sulphur yellow patch on the recurving front lobe. *Dendrobium formosum* is distributed somewhat widely over the East. It was in the first instance sent home by Gibson (the Duke of Devonshire's collector) from Khasia nearly sixty years ago. Since then it has been discovered and imported from Burmah, the Andaman Islands,

and other districts. Like most of the *Dendrobiums* with black hairs on the stems, it is not easy to keep it in good health for many years after importation. It is quite a tropical species, and during the growing period should have abundant heat and moisture and scarcely any shade. Several plants of the variety *giganteum* are flowering nicely in the Orchid house at Kew.

## ROSE GARDEN.

### OCTOBER ROSES.

HERE in the west of England we never had so few Rose blooms in the month of October as we have had this year. I am not speaking of Roses

of all are, I think, *Gloire de Dijon* and *Rêve d'Or*. These two useful autumn Roses are generally well laden with flowers at this time of year, and in a mild time frequently give plenty of handsome buds up to near Christmas, but now one has to search to find a passable flower. We do not want any better evidence than this, that even these free-flowering kinds cannot thrive in a dry root medium, nor can we wonder that mildew runs riot over these and others. *Souvenir de la Malmaison* is pretty clear from this pest, and is the only one that has given blooms of any value. Last year at this time Mrs. Paul furnished a few good blooms, but at the present time there are no signs of any flowers. Amongst strong-growing Roses, William Allen Richardson is certainly the most satisfactory autumn variety we have in a dry season. A large bush-plant growing in the open has furnished more flowers than any other, and still promises to continue doing so.

With regard to the Teas, the value of a deep and fairly rich root medium for them was never more manifest than during the present season, and even where this has been provided the want of root moisture is very evident in the weak growth and the presence of mildew on all varieties alike. At the same time there are less mildew and more flowers where a depth of good soil has been provided. Such weak growers as *Mme. Charles*, *Ma Capucine*, and *Ethel Brownlow* cannot make any progress when the foliage is laden with mildew, and should only be planted where the roots can have all the moisture they require.

Amongst the Hybrid Perpetuals none has surprised me more in its behaviour than *Her Majesty*. One always expects to see this Rose stricken with mildew even in a favourable season, but when that pest is more severe than usual in its attacks, I hardly expected to see a single plant developing three good flowers at the end of September. I find old plants of this Rose are more perpetual in character than young ones, and when the roots are well nourished he blooms on old plants are but little inferior in size and substance. Where all the plants have suffered from mildew more or less, I do not think it would be wise to single out any as likely to be able to withstand such an enemy another year. The three least affected by it under present conditions are *Victor Hugo*, *Etienne Levet*, and *Magna Charta*. J. C. CLARKE.

### NOTES ON ROSES.

IN an interesting article on autumn Roses in THE GARDEN of September 21, page 213, the following statement occurs: "Augustine Guinoisseau, which really has no resemblance to *La France*, but stands out conspicuous on its own merits, is one of the freest, sweetest and most persistent of

bloomers." I am much astonished to find anyone making this statement, for the Rose in question has never been claimed as a seedling, but both in foreign and English catalogues has been classed as a sport from *La France*. It is identical with it in form, in the shape of the petals, in growth, freedom of flowering and perfume. The National Rose Society's catalogue of exhibition Roses, which was drawn up by some of the most experienced Rose growers in the country, describes it as a sport from *La France*, and I have often heard these growers say that they could go through a row of *La France* and find flowers which they could stage as *Augustine Guinoisseau*. With regard to these Hybrid Tea Roses, there seems to be a craze amongst the foreign raisers, which some of our English rosarians have not been slow to take up, to class many of their productions under this head instead of placing them where they

*Campanula persicifolia alba*. (Fig. 12. See p. 299.)

in nursery quarters or in gardens where they are exceptionally well cared for, but of Roses where the plants have only ordinary attention. In all the cases that have come under my notice there is a great dearth of flowers. The reason of this is not far to seek. The long drought and excessive heat are quite sufficient to account for this state of things, for although we had some dull weather and some showers of rain in the middle of the summer, sufficient moisture has not fallen to reach the roots of the Roses since May last. The most surprising

*Campanula pyramidalis*. (Fig. 13. See p. 299.)

used to be formerly—amongst Hybrid Perpetuals, Teas and Noisettes. Thus Guillot, who brought out *La France* nearly thirty years ago as a Hybrid Perpetual, moved it into this class, and with it of course went its various sports—*Danmark*, *Augustine Guinoisseau* and *Duchess of Albany*. In the same way *Capt. Christy*, which we have always regarded as a Hybrid Perpetual, has also been foisted into this class, and the craze seems to be going on. Thus that fine new Rose of Alex. Dickson and Sons, *Mrs. W. J. Grant* (alias *Belle Siebrecht*), is called a Hybrid Tea, instead of being classed (as I think it ought to be) as a Hybrid Perpetual. We may well ask, where is the evidence

of cross-breeding in Kaiserin Augusta Victoria? It is to all intents and purposes a pure Tea, inclining towards the Noisette section, but having no affinity to a Hybrid Perpetual that I can see. So, again, that good garden Rose of Mr. Geo. Prince—Clara Watson—instead of being called a Hybrid Tea should surely be a Hybrid Perpetual. Neither in perfume nor habit can I see any appearance of Tea blood, though of course, as Roses have been so much hybridised either naturally or artificially, it is very difficult to say what blood may not have entered into their composition; but this would be applicable to all Roses, and therefore could not be distinctly claimed by any. It is never well to multiply divisions, and I have for some years strongly advocated the plan of putting Hybrid Perpetuals, Hybrid Teas and Bourbons into one class, giving them all either the name of Perpetuals or Hybrid Perpetuals. This would end the confusion that now prevails and is likely still further to increase, as I see that the French growers are still announcing a considerable number of Hybrid Teas. There is one autumn-blooming Rose to which I would draw attention—*Beauté Inconstante*. It is one of these small Tea Roses allied to W. A. Richardson and l'Idéal, which go under the name of button-hole Roses; like them, it is of long growth, and the colour of the flower is one of those indefinable mixtures of apricot, peach and copper which people sometimes called terra-cotta, but it is very bright and admirably suited for this purpose. I recollect noticing the single Rose exhibited by Mr. Frank Cant to which Mr. Orpen alluded in a recent issue, and it struck me at the time that, though very like *Bardou Job*, it was quite distinct from it. Although I have not grown it myself, I understand from those who have, that *Alister Stella Grey* is likely to be a very valuable small Rose for continuous blooming. It will form a good companion to W. A. Richardson, of a different shade of colour, but somewhat in the same style. It was raised by Mr. Alexander Hill Grey, one of our most enthusiastic growers of Tea Roses.

DELTA.

## SEPTEMBER IN SOUTH DEVON.

THE past month has been exceptional, both on account of its dryness and warmth, as well as from its immunity from wind. The rainfall has only amounted to 0.01 of an inch, though 0.27 of an inch fell between midnight on September 30 and 9 a.m. on October 1, and must, therefore, be added to the month's real rainfall by the Meteorological Society's rule. The rainfall of September, 1894, was 3.05 inches, and the average for the past nineteen years is 2.34 inches. From January 1 to the end of September the total amount of rainfall was 16.83 inches, with ninety days on which not less than 0.01 of an inch was measured. Last year for the same period the rainfall was 25.55 inches, with 150 wet days, the average fall for the nine months being 23.30 inches; so that at present we are 6.47 inches below the average. The dews were exceptionally heavy, even for September. The amount of sunshine registered was 213 hours 45 minutes, against 156 hours 5 minutes in September, 1894, and an average of 164 hours 25 minutes. There was only one day in the month on which the sun did not shine. The amount of sunshine registered for the first nine months of the year reached 1644 hours 15 minutes, while that for the same period of last year amounted to but 1364 hours 20 minutes, or nearly 280 hours less. The mean temperature was 60.9°, being 3.1° above the average mean temperature of September. The highest temperature recorded in the screen was 73.9° on the 28th, and the lowest reading on the grass 43.0° on the 17th. These readings show that the South Devon seaboard has been particularly favoured during the period of abnormal heat that has been experienced throughout the kingdom. The total horizontal movement of the wind was 3175 miles, the month having been the calmest for the last two years.

The garden, despite the drought, has been gay with autumn flowers, the drenching dews having

kept the lawns green and the herbaceous plants from flagging. The Starworts, with their varied colours and heights, have made the borders beautiful with tender gradations of tints ranging from lilac-blue to white. The first to open was the white *Harpur-Crewe*, to be followed by the large-flowered and brightly-coloured *Amellus bessarabicus*, *Archer-Hind* and the 6 feet high *Robert Parker*, the latter, with its wealth of pale mauve flowers, being perhaps the most effective of all the Asters. *Pluto*, a dark-flowered variety of the *Novi-Belgi* section, is worth a place in the border, as is *A. puniceus pulcherrimus*, a good large-flowered white. The beautiful *A. ericoides*, in great request for indoor decoration, and even more graceful than the somewhat similar *A. cordifolius* and its lilac-tinted variety *A. c. elegans*, should be grown in quantity, and, for the sake of old associations, *A. diffusus horizontalis*, the commonest Starwort in the cottage gardens, and a pretty sight when smothered in its inconspicuous maroon and white blossoms, should not be omitted. Of the *Novæ-Angliæ* section the best are *ruber*, a dark rose colour, and *Melpomene*, purple. *Pyrethrum uliginosum* has produced its large, narrow-petalled white stars in profusion, sheaves of its long, graceful flower-scapes being cut for arranging in tall vases. Of yellow, an abundant display has been afforded by the *Helianthus* family. A line of *H. giganteus* at the boundary fence has carried a wide fringe of saffron over 8 feet high. *H. latiflorus*, with its rich gold and black centred blossoms, has made a fine effect against an evergreen background, while *H. multiflorus* and *H. m. Soleil d'Or*, *H. rigidus* (of which the variation named *Miss Mellish*, now to be seen in perfection at Kew, is a distinct advance upon the type), the annual Sunflowers, both the giant, with their large, dark discs, and the miniature strain, the *Rudbeckias*, early *Chrysanthemums*, and yellow *Cactus Dahlias* have all added their quota to the preponderating tone of colour. Of reds, we have had long spires of the thorny-leaved *Erythrina crista-galli*, the last spikes of *Lobelia cardinalis*, the scarlet *Cactus Dahlias* and the *Tropæolums*, while the tuberous *Begonias* have, week by week, increased the splendour of their dazzling carpet. The white *Everlasting Pea* (*Lathyrus latifolius albus*), that was badly injured by the severe winter, did not open its first blossoms till well into the month, and the standard *Magnolia grandiflora*, which shed all its earlier buds, has made a second and more successful attempt at flowering, and produced a number of its fragrant white chalice during September. The *Belladonna Lilies* have flowered well, and the row of *Anemone japonica alba* has been throughout the month a white cloud beneath the ivied wall. The last of the *Lilies*—*L. tigrinum Fortunei*—has been remarkably fine, having grown to a height of over 6 feet. This variety is, with me, distinctly the most satisfactory of the *Tiger Lilies*. Two tall Palm-like plants of *Aralia spinosa*, now fully 15 feet high, have flowered for the first time, and, with the straight shafts of their stems shooting up from an undergrowth of *Cannas*, *Hedychiums*, and *Acanthi*, have put a finishing touch to the broad outlines of a sub-tropical picture. The most noticeable of the September Roses has been the white *Macartney*, which, commencing to bloom in July, has not since let a day pass without the opening of two or three delicately scented single blossoms, sometimes 4 inches in diameter, with the snowy petals of which the golden stamens form a harmonious contrast. The large *Hydrangea* bushes with their wealth of massive blossoms, now pink, now almost white, sometimes of well-nigh *Forget-me-not* blue, have lighted up the verges of shady paths and bloomed on sunny banks with equal vigour. *Solanum jasminoides*, which, associated with the scarlet *Tropæolum* that had scaled the house-wall, furnished such a striking colour-picture during August, in September was associated in an even more beautiful combination of tints. *Ampelopsis Veitchi* had grown behind the wires on which the long flower-sprays of the *Solanum* wandered and swayed, and for a full week from the caves downward the

white bloom-clusters stood out against the background of the crimsoning creeper, a sight beautiful as it was fleeting, for the month's end saw the background vanished and the crimson leaves lying among the *Heliotrope* beneath.

September has been a fine month for the ripening of outdoor fruit, the Peaches having swelled up well and coloured grandly. *Sea Eagle* has been especially satisfactory, many fruits on a tree bearing a good crop having reached nearly 1 lb. in weight. Pears, although not a heavy crop, have been individually fine, one fruit on a young tree of *Triomphe de Vienne* weighing 27 oz. Apples have been a heavy crop, *King of the Pippins*, which bore prodigiously last year, being almost the only failure. *Cellini* and *Barnack's Beauty* have produced exceptionally fine fruit, and of *Cox's Orange Pippin* a fair crop in good condition has been stored. Of large cooking Apples, *Warner's King* and *Gloria Mundi* have both fruited well, and *Bismarck* has perfected a fine crop, the small trees being loaded with large fruit, running from a half pound to 1 lb. apiece in weight. *Lane's Prince Albert* has also borne heavily. *King of Tompkins County* does very indifferently here, and lacks the bright colouring of imported fruits of this variety. S. W. F.

## SOCIETIES AND EXHIBITIONS.

## ROYAL HORTICULTURAL SOCIETY.

OCTOBER 15.

THE Drill Hall was again crowded on this date with exhibits of the most comprehensive character. These were also very remarkable for their high-class quality, whether it be in plants, fruits or vegetables. Amongst plants the post of honour must be accorded to Mr. Wythes' large exhibit of *Nepenthes*; some two dozen splendid examples of the best and newest kinds (but few being in duplicate) were staged. The pitchers were very finely developed and in good character for the respective varieties, the new and rare *Veitchian* hybrid, *N. mixta*, being especially noteworthy. The gold medal was most deservedly awarded to this exhibit. *Crotons* from Mr. H. B. May, finely grown and of rich colour, showed the great value of these plants for decoration. Orchids were present in the greatest abundance. Of these, *Cattleya labiata*, now in its season, was represented by several superb forms, notably a very fine white variety. The rare and unique *Lælia Dominicana*, of the richest colouring, was also present from the *Dell* collection, whilst from Messrs. Sander came a grand plant of the singular *Habenaria Susanna* in unusual vigour. *Chrysanthemums* are already well advanced, a fine group from the *Ryecroft* collection being staged, as well as several new and noteworthy kinds from the best growers. *Dahlias*, still holding out well, testified to the favourable state of the weather, the singles in this instance being the most prominent.

Fruit was present in great abundance and in large variety also. From *Sawbridgeworth* came a very fine assortment of the best Apples, the perfect finish and colour being most remarkable, some of these being orchard house fruit. A large and fine collection was also staged by Messrs. *Veitch and Sons*. This comprised varieties only that were not shown at the *Crystal Palace*, hence not quite so large as on that occasion, but the present exhibit was valuable in that it proved that, over and above the 100 kinds shown at the *Palace*, it is not by any means a difficult matter to stage yet another 100 sorts of excellent quality. The conditions under which this exhibit was staged were clearly indicated, but by many they were not fully realised. Other and smaller exhibits of fruits were very numerous, *Melons* being still in good condition, whilst of *Pears*, two very highly coloured dishes of *Doyenné du Comice* were shown by Mr. Hill from *Tring Park*; these were notable by their perfect finish and high-class colour. An award of merit was

most deservedly given to a new late Plum from Messrs. Rivers, which bids fair to be the finest late kind grown for cooking. Of vegetables there was one large and most meritorious exhibit from Mr. Beckett, a well-known cultivator. Every dish in this collection (as comprehensive as it could well be) was of the highest excellence, and it deserved a better award than it obtained. Other exhibits comprised abnormally large Onions, good Leeks, and Celery.

#### Orchid Committee.

At this meeting first class certificates were given to—

**CIRRHOPELALUM ROTHSCHILDIANUM.**—A very distinct and remarkably fine species of this singular and interesting genus, the flowers much larger than in most species. The colour of the entire flower is a dark vinous red with bronzy suffusion; the tail-like sepals, broad at the base, are fully 6 inches in length, while the greenish yellow at the base affords a pleasing relief. Shown from Lord Rothschild's collection at Triog by Mr. Hill.

**CATLEYA LABIATA COOKSONI.**—A pure white form and the finest in its way yet seen; the sepals and petals are of the purest white, the latter being also of extra breadth; the lip has the central part of the brightest crimson-purple, with a well defined white margin. This fine form was greatly admired. From Mr. Norman S. Cookson, Wylam-on-Tyne.

Awards of merit were made to the following:—

**CATLEYA MANTINI** (C. Dowiana × C. Bowringiana).—A very beautiful hybrid, but one in which the well-known features of its former parent are greatly subdued, its stamp being chiefly visible in the golden veins in the throat. The colour is deeper than in the best forms of C. Bowringiana, the sepals and petals broader, the lip of a deep purple shade, and the plant of dwarf habit. From Messrs. James Veitch and Sons, Chelsea.

**SOBRALIA LINDENI.**—A distinct species of moderate growth with white sepals and petals, the lip mottled with crimson and relieved with white. The flowers had apparently suffered in transit, hence it was not seen to the best advantage. From Mr. Lucas, Warnham Court, Horsham.

**CYPRIPEDIUM ALFRED HOLLINGTON.**—A very fine hybrid, the parentage of which was not given, but in which C. Curtisii was very discernible, being in all probability one of its parents; the pouch was after C. Curtisii, but of the two larger and quite as dark in colour; the petals partake of the same drooping character with somewhat similar markings, being also longer. The dorsal sepal is broad, but pointed, with dark purplish veins. The spike bore twin flowers, whilst the habit is vigorous. From Mr. Hollington, Forty Hill, Enfield.

**MILTONIA COBBIANA.**—A distinctly superior form of the M. Clowesi section, the lip much larger and finer, and also clearer in its markings; the sepals and petals are darker in colour, the same being well defined. From Mr. Cobb, Dulcote, Tunbridge Wells.

**CATLEYA LABIATA** (Thompson's var.).—A very superior form with flowers of unusual size and substance, the petals being of extra breadth also; both sepals and petals are much deeper in colour, whilst the same remark applies to the labellum, which is of an intensely deep crimson-purple, the margin being delicately fringed. From Mr. Thompson, Stone, Staffs.

**CATLEYA LABIATA CERULEA.**—A distinct and noteworthy form, and as such deserving of the award, but it is not so handsome as the preceding by any means. The sepals and petals are slightly flushed, whilst the lip is of a pale purplish tint, the individual flowers being of large size. From Mr. Thompson.

**CYPRIPEDIUM CHARLESWORTH MARGINATUM,** which chiefly differs from the type in having the dorsal sepal of a much lighter shade, the central part of which is nearly white with a slight tinge

of rose towards the margin and darker at the base. From Mr. Thompson.

Mr. Gurney Fowler, Woodford, Essex, had an extra rich and finely cultivated group, in which were included several excellent varieties of *Cattleya labiata*, bearing a profusion of bloom. In the same collection was to be seen a grand example of *Epidendrum Godeffianum*, with long terminal spikes of bloom, the bronzy sepals and petals with the rosy lilac lip being very effective. *Vanda cerulea* in the same collection was excellent, and so was *Miltonia Moreliana*, but slightly paler than usual (silver Flora medal). Messrs. Sander and Co. had an excellent group, which included both cut specimens and plants of *Dendrobium Phalaenopsis Schrederianum*, showing a wide range of colour. *Oncidium Marshallianum* was very fine, the spike a dense one. *Cattleya labiata* was also present in fine varieties. Of *Zygopetalum Gautieri* an excellent example was shown, its novel colouring making it most distinct, the lip being of an intensely dark shade. *Habenaria Susanna* was particularly fine, the long spikes bearing large pure white blossoms, with the lip deeply serrated. Both *Sophranitis coccinea* and *S. grandiflora* were present, as also was *Miltonia Moreliana*. *Lælia Perrini nivea*, a pure form both beautiful and rare, was much admired here. An imported *Lælio-Cattleya* was also shown, bearing some resemblance to *L. elegans* in the tinting, but the lip was that of a *Cattleya* and deep purple in colour. *Cattleya labiata lilacina*, very distinct in its marking, with only one slight splash of purplish crimson on the lip, was quite distinct. Of *Cypripediums* there were *C. ananthum superbum*, *C. Niobe*, *C. Tityus*, *C. Albert Truffaut*, and *C. Thayerianum*; and of curious *Orchids* there were *Mormodes* species, very dark in colour, and *M. buccinator*, with *Catasetum* species, an intensely dark kind. *Epi-Lælia Hardyana*, a most beautiful hybrid, with long narrow sepals and petals slightly tinted with rosy lilac, and the lip a deep vinous purple, was also noteworthy (silver Banksian medal). Messrs. B. S. Williams and Son sent a very interesting group, which comprised a beautiful example of *Oncidium incurvum* full of flower. *Oncidium ornithorrhynchum* was also shown, as well as *Odontoglossum grande* and those difficult-to-cultivate *Orchids*, *Pescatorea Lehmanni* and *P. Klambochorum splendens*. *Cattleya labiata* was included also, as were several choice hybrid *Cypripediums*, as *C. Peetersianum*, *C. Pitcherianum* (Williams' var.) and *C. ananthum superbum*, with others. *Pleione lagenaria* also made its appearance here (silver Banksian medal). Messrs. H. Low and Co. had a remarkably fine collection of *Cattleya labiata* in great variety and of high class quality, the growth of the plants being very robust and sturdy. One form called *Lowe* was also shown. It has white sepals and petals, with a crimson-purple lip, being much in the way of *Cooksoni*, but as the flowers were scarcely expanded one could scarcely judge of its real merits. Another very dark form was shown here with the lip yet darker. *Phalaenopsis Portei* and *Bulbophyllum mandibulare* were also included here (silver Banksian medal). A cultural commendation was awarded to Mr. Thompson for a very fine example of *Vanda Kimballiana* bearing seven spikes, most of which were expanded.

Of other exhibits, Messrs. Veitch and Sons had several hybrid *Orchids*, including *Lælio-Cattleya Eunomia superba* (C. Gaskelliana × L. pumila), which might be described as a glorified *L. pumila*, the lip extra fine and deep in colour; *L.-C. Parysalis* (L. pumila × C. Bowringiana), of very dwarf habit, and *L.-C. Fortuna* (L. elegans alba × C. Mossie), the sepals and petals of which were slightly flushed, and the lip with a dark crimson blotch. *L.-C. Isis* (C. Mastersonia × L. pumila), dwarf in growth and bearing large flowers of a bright rose colour, was very striking here. From Sir William Marriott, Blandford, came *Cypripedium Marriottianum*, a white hybrid with dark veins and spots. From Baron Schröder came *Lælia Dominiana*, an almost unapproachable hybrid of most intense colouring, the lip

being of a rich velvety maroon shade, relieved with faint golden lines; this is a gem amongst hybrid *Orchids*. *Lælia Perrini alba* was also shown with pure snow-white flowers from this source. Mr. Ebner, Beckenham, showed two distinct-looking hybrid *Cypripediums*, the names of which were not intelligibly written. In Mr. Statter's exhibit were to be seen a few rare and choice things, as *Cattleya bicolor cerulea*, with pale greenish yellow sepals and petals, with a clouded or lavender-blue lip; also *C. aurea* (Stand Hall var.), in which the rich yellow petals were tinted with the colour of the lip. *C. aurea*, in good form, was also shown, as well as *Lælio-Cattleya Parisiana*, a very distinct-looking hybrid, with rosy mauve sepals and petals and a rotund lip of crimson-purple. A small collection of *Orchids* came from Mr. McArthur, Maida Vale, which comprised forms of *Cypripedium Charlesworthi*, *C. Tennyson*, a bright-looking hybrid, also *C. insignis Gortoni*, with *Cattleya labiata* and *Oncidium varicosum Rogersi* bearing good spikes. From Mr. Thompson came, in addition to the certificated plants, the following: *Odontoglossum Pescatorei*, a very distinct variety with pure white sepals and petals, the characteristic spots being very bright and dark in colour, a most beautiful variety and the spike a very fine one. *O. Harryanum* was represented by a very fine spike of large flowers, with the colouring deeper than usual. *O. Schrederianum*, a singularly distinct species with reflexed sepals and petals of a dark tint, with the lip half white and half rosy purple, a pretty variety, and *O. crispum Thompsoni*, a fine form bearing large massive flowers, thirteen to the spike, were also very conspicuous. From Messrs. Charlesworth and Co., Bradford, came a grand mass in profuse flower of *Vanda cerulea*, with seven spikes of bloom; also *Cypripedium Charlesworthi* in variety, as well as *Catasetum Bungeoethi*, *Cattleya labiata*, *Odontoglossum crispum* and *Vanda Kimballiana* extra fine with large flowers. Mr. Hollington had another hybrid *Cypripedium* in *C. A. J. Hellington*, with creamy yellow flowers faintly spotted, and from Mr. Fowler came, in addition, *Vanda Sanderiana*, with extra fine flowers, the markings deeper than usually seen. Mr. de B. Crawshaw showed *Vanda Kimballiana* (Mrs. Studd's var.), a fine and distinct form with pure white sepals and petals, but broader than in the type, the lip also larger. Sir F. Wigan showed the singularly beautiful *Ceologyne pandurata*, a fine spike of flowers. From Mr. Ashworth came a hybrid *Cypripedium*, the flowers of which had been cut the previous day after being fully expanded for three months and seventeen days, and still fairly good. Mr. Lutwycho showed *Oncidium tigrinum*, a particularly fine spike of this beautiful cool house species. Of Continental exhibits there, came from Mons. A. A. Peeters *Cattleya labiata Peetersiana*, which has mottled sepals and petals and lip, the colouring also deep and strangely commingled; the effect scarcely beautiful, but distinct. *Cypripedium François Peeters*, of dwarf habit and with dark vinous-purple flowers, came from the same source.

#### Floral Committee.

The exhibits before this committee were interesting and varied.

First-class certificates were given to the following:—

**PHYSALIS FRANCHETTI.**—We have previously described this remarkable plant, one of the choice things recently brought from Japan by Mr. James Veitch. Picture to oneself a much enlarged edition of the ordinary *P. Alkekengi* and one has a good idea of this new introduction. The bladder-like covering to the calyx is about 2½ inches long and the same in breadth, but the size varies somewhat, as also the colouring, which is sometimes intense scarlet and sometimes shaded with yellow, the colouring depending upon the ripeness of the fruit. Messrs. J. Veitch and Sons showed this splendid hardy plant, so free, bold, and brilliant in colour, not so pleasing, it is true, as in the old kind, but creating a superb picture at this season in the open. Its

huge fruits are very handsome, too, in large decorations.

**ABIES DOUGLASSI GLAUCA PENDULA.**—It is, of course, very difficult to judge of an Abies in a pot, but we think this is a good variety. Its foliage has quite a glaucous tone, and the branches are conspicuously pendent. From Messrs. Paul and Son, Cheshunt.

An award of merit went to each of the following:—

**CHRYSANTHEMUM LAGO MAGGIORE.**—A very handsome variety of the Japanese class, the flower large, not stiff, the outer petals drooping gracefully and rich yellow in colour. We admire this variety because free from coarseness, and the colour is both decided and rich. From Mr. H. Briscoe-Ironside, Cedar Lodge, Burgess Hill.

**CHRYSANTHEMUM LADY ESTHER SMITH.**—A beautiful incurved Japanese variety, the flower compact and dead white. A distinct and welcome introduction. From Mr. Owen, Maidenhead.

**CHRYSANTHEMUM (POMPON) YELLOW GEM.**—This is well named. It is a gem amongst this class, the flowers of delightful form, pure yellow and fimbriated. A large bunch of it from Mr. Owen, was one of the best things of the meeting.

**CHRYSANTHEMUM PHŒBUS.**—A very large and handsome flower, one of the most striking of recent introductions. It is broad without coarseness and the colour is of a bright and pleasing yellow. Shown by Mr. H. J. Jones, Ryecroft Nursery, Hither Green Lane, Lewisham, and Mr. Shoemith, of Woking.

**CHRYSANTHEMUM BOULE D'OR.**—One of the incurved Japanese class, the flower large, rather pale yellow, with bronzy lower petals. Exhibited by both Mr. H. J. Jones and Mr. Wells, Earlswood Nurseries, Redhill.

**CHRYSANTHEMUM PRIDE OF MADFORD.**—A striking flower, large, as the majority of the new kinds, and belonging to the Japanese class. The florets are purple-rose with silvery reverse, a pleasing harmony of colour. From Messrs. H. Cannell and Sons.

**CHRYSANTHEMUM T. B. HAYWOOD.**—A beautiful Japanese variety, the flower large, refined, and of the purest white. From Mr. Salter, gardener to Mr. T. B. Haywood, Reigate.

**VIOLET PRINCESS OF WALES.**—A very large, rich blue Violet, the flowers sent by Messrs. Cannell having been gathered from the open ground, and, what is of great importance, one gets a full, rich perfume. From Messrs. Cannell and Mr. Owen Thomas, gardener to Her Majesty the Queen, Frogmore.

**BEGONIA MRS. HEAL.**—This is another splendid hybrid raised by Mr. Heal, and is the result of a cross between a tuberous variety and *B. scottrana*. The plants shown were quite distinct, sturdy in growth and bearing a profusion of warm carmine-rose flowers. Individually they are of fine shape, almost round, robust, and carried in clusters, as it were, the plants being a mass of colour from the many bright blossoms. It is a decided advance, and in time doubtless this winter-flowering race will rival for brilliancy and usefulness the glorious varieties that make the garden gay in summer and early autumn. From Messrs. J. Veitch and Sons.

**CARNATION J. GARDINER MUIR.**—A very delicately-coloured Carnation with a fringed petal. The flower is large, strongly scented like the Clove, and white, with a soft salmon centre; the plant is strong in growth and very free-flowering. We value it, not only for its strength and refined colour, but especially for its fragrance, wanting unfortunately in many varieties, such as that much-praised kind, Mrs. Leopold Rothschild, which was shown with J. Gardiner Muir. We protest, however, against the name; it is ugly and unnecessarily long. From Messrs. J. Veitch and Sons.

The chief group came from Mr. G. Wythes, gardener to Earl Percy, Syon House, Brentford, and the highest award (a gold medal) was deservedly given to it. The collection of plants consisted chiefly of Pitcher Plants (*Nepenthes*),

and we think very few gardens could produce such an interesting display. The group was well arranged, Crotons, Dracaenas and Ferns forming a groundwork, as it were, to the *Nepenthes*, each of which was remarkably well "pitchered," and comprised both old and recent kinds. Especially fine was that beautiful kind *N. Mastersiana*, which we think is one of the best of the family. Conspicuous also was the comparatively new hybrid, *N. mixta*, about which we have written before in *THE GARDEN*. *N. Hookeriana*, *N. Chel-soni*, *N. Amesiana*, *N. Dicksoniana*, *N. Curtisi superba*, *N. Raflesiana*, *N. Wrigleyana* and *N. Northiana* were amongst the best grown, whilst of the fine-foliaged plants we noticed splendid plants for colour of that graceful, narrow-leaved Croton named *Countess*. The group occupied the best part of one side of the Drill Hall. A silver-gilt medal went to Mr. H. B. May, The Nurseries, Dyson's Lane, Edmonton, for one of the most delightful groups we have seen from this firm. The Crotons and Dracaenas made as bright a display almost as a bank of flowers. Of the Crotons we may mention *Alexandra*, *Nestor*, *aneitensis* (very beautiful), the leaves rather narrow and yellow barred with green; *majesticus*, *ruberrimus*, red and green in its leaf colouring, *Thomsoni*, a broad leaf, and marked with green and yellow. A new Carnation named *Primrose Day* is a pleasing yellow variety, and a new Fern named *Pteris cretica Wimsetti* was noteworthy, the growth dense, and the tips of the fronds densely crested. The same award was made to Mr. H. J. Jones, of Lewisham, for his tastefully set-up group of *Chrysanthemums*. The plants were not densely put together, as the fashion was recently, but each kind could be well seen, the base of the group Ferns, *Araucaria excelsa*, and other fine-foliaged plants. George Biron was conspicuous amongst Japanese varieties, the flowers dull red with old gold reverse, and one noticed a mass of that splendid little Japanese kind for cutting, *Ryecroft Glory*, the flowers rich yellow. Mr. Jones also had numerous new kinds in boxes, some of which have been already described. Mrs. D. Airdrie, white, M. G. Montigny, pink, incurved Japanese, and Emily Spilsbury, of purest white, are valuable introductions. A silver medal was awarded to Mr. T. S. Ware, Hale Farm Nurseries, Tottenham, for a bunch of single-flowered Dahlias, but as we have already made many notes on Dahlias this season, it is unnecessary to again allude to the rich selection here presented. *Lilium nepalense*, illustrated by a coloured plate in *THE GARDEN*, January 19, 1889, and *Nerines* in many forms comprised this bright and interesting group. A bronze medal was awarded to Mr. W. J. Empson, gardener to Mrs. Wingfield, Amptill House, Amptill, for a group of indoor plants.

Among other contributions were the following: Mr. Owen, Maidenhead, showed some very fine blooms of new October-flowering *Chrysanthemums*, such as *C. Bernard*, a bright chestnut-red Japanese variety; *M. Backmann*, very pretty, buff, tinted with red; *Lady Ridgway*, bright yellowish buff, reverse reddish in colour, and others noticed above. Messrs. Cannell and Sons showed many interesting exhibits. The beautiful single Violet has been already described, and a word of praise must be given to the valuable series of zonal *Pelargoniums*, such as *Mme. Beuvron*, pink, with a multitude of crimson spots in the centre, *Lady Newton*, salmon-pink, a lovely variety, and *Belle Alliance*, a neat little flower, white, freely dotted with purple, besides several bunches of *Canna Queen Charlotte*, a brilliant variety, carmine, edged with rich yellow. Mr. Anthony Waterer, Knaphill, Woking, showed a boxful of flowers of that fine variety of *Spiraea Bumalda* named *Anthony Waterer*. It was exhibited to show how late in the year it flowers. Messrs. J. Veitch and Sons had *Caryopteris mastacanthus*, a bright purplish, hardy-flowering shrub, very charming at this season, and Messrs. Paul and Son showed late autumn flowers, amongst them that fine perennial, none too well known, *Rudbeckia purpurea*, its flowers rosy purple in colour.

They also had plants of the pot Rose Winter Bloomer, a neat flower of the Catherine Mermet character, rosy in colour and deeper at the edge, the perpetual blooming climbing Rose *Alister Stella Gray*, and plants in bloom of *Caryopteris mastacanthus* lifted from the open. Mr. Salter, gardener to Mr. T. B. Haywood, Reigate, showed seedling *Chrysanthemums*, one described above and another named Mrs. H. B. Higgins, a seedling raised in Australia. Its white flowers were about 11 inches across. Messrs. Dobbie and Co., Rothesay, had flowers of single Cactus Dahlias and Shirley Poppies so-called, but which are only improved forms of the field Poppy. Mr. G. F. Wilson, Heatherbank, Weybridge, showed a plant in full flower and lifted from the open of *Tricyrtis hirta*. Messrs. Veitch and Sons showed a group of *Lilium longiflorum Harrisii*, and Mr. Briscoe-Ironside a rotary arrangement for cut flowers, which is a useful and artistic contrivance.

We must not omit to mention the beautiful climbing pillar *Begonias* from Messrs. Sander and Co., St. Albans. *Duchess of York* has bronzy-red leaves, *Duke of York* is of a similar metallic lustrous colour, and another lovely variety is *Princess of Wales*, the leaves quite silvery. *Sarracenia Drummondii major* is an exquisite variety; the pitchers are light green for the most part, the mouth veined with crimson. The same firm had a charming series of hybrid *Sonerilas*. One named *Silver Queen* has leaves of a self silver tone. Messrs. B. S. Williams and Son, Upper Holloway, showed a collection of *Nerines*, *N. Moorei*, brilliant scarlet, *N. sarniensis*, rose, and *N. flexuosa*, rose, being noteworthy. A collection of cut flowers of leading *Chrysanthemums* came from Mr. Owen Thomas, Frogmore, Mrs. Harman-Payne and *Avalanche* being very fine.

#### Fruit Committee.

The exhibits before this committee were numerous, many of them of special merit. Vegetables were excellent; Apples and Pears being also staged in quantity. Melons were deficient in flavour, and the new varieties of Grapes staged did not compare favourably with older varieties.

An award of merit was given to—

**PLUM RIVERS' PRESIDENT.**—A large black fruit, somewhat like *Monarch*, but much later and of very good flavour, considering the time of year. It is a freestone and is said to crop freely.

A very fine collection of fruit was sent by Messrs. Rivers, Sawbridgeworth, the Pears being noted for their splendid finish. Mention must be made of *Conference*, *Magnate*, a very large yellow fruit; *Princess*, *Fertility* and *Beacon*, new seedlings of great merit. There were very fine dishes of *Durondeau*, *Nouvelle Fulvie*, *Lebrun*, *Doyenné du Comice*, *Glou Morceau*, *Beurré Diel*, *B. Alexander Lucas* and *B. Bachelier*. Some grand baskets of *Cox's Orange Pippin*, *Rivers' Codlin*, *Bijou*, *Cellini*, *Peasgood's Nonsuch*, *Crimson Queening*, *Beauty of Kent*, *Ecklinville*, *New Hawthornden*, *Ribston* and other good dessert kinds were included, well meriting the silver-gilt Knightian medal awarded. Messrs. Veitch, Chelsea, sent over 100 dishes, mostly dessert Apples and Pears. There was also a very fine lot of the new *Physalis Franchetti*. Some very good alpine Strawberries, *White Grape Currants*, and fine fruits of *Superlative Raspberry*, the best late Raspberry grown, were also staged (silver Knightian medal). Messrs. Paul and Son, Cheshunt, staged 100 dishes of Apples, *Ribston*, *Cox's Orange*, *Nonpareil*, *Cellini*, *Cox's Pomona*, *Peasgood's Nonsuch* and *Alfriston* being excellent (silver Knightian medal). Mr. Rockwood, Fulwell Park Gardens, Twickenham, also staged 100 dishes of Apples and Pears, kinds well known and mostly mentioned above (silver Banksian medal). Mr. E. Beckett, Aldenham House, Elstree, Herts, staged a remarkable lot of vegetables, the quality being superb—in fact, so many fine dishes are rarely seen in a single collection. Veitch's Autumn Giant Cauliflower was grand, the heads pure white, close and firm. Celery, Kales in variety, Savoys, Cabbages, Coleworts, Telegraph Cucumber (excellent), Student

Parsnip, Artichokes in variety, Scarlet Model and Intermediate Carrots, Perfection Tomato and very good Mushrooms were well represented. The exhibit was well set up and deserved the award given (silver-gilt Knightian medal). Mr. Divers, Belvoir Castle Gardens, Grantham, staged twenty-four varieties of Celery, the best being Major Clarke's Red, Superb Pink, Early Rose, Standard-bearer, Wright's Grove Pink and Man of Kent, with other old kinds such as Sandringham, Gem and Conqueror (silver Banksian medal). Messrs. Dobbie, Orpington, Kent, sent very fine Champion, International and Selected Leeks, very good Kales, beautifully curled; also Parsley and immense bulbs of Ailsa Craig and Sandy Prize Onions, with very fine examples of Selected Parsnips (silver Banksian medal). Mr. Jones, Greenford Place, Sudbury, sent four varieties of Leeks—the Lyon, Ayton Castle, Champion and Sutton's Prize-taker well grown. Messrs. Deverill, Banbury, sent very large Onions—Anglo-Spanish and Ailsa Craig. Mr. Young sent a seedling Tomato. Mr. Wells Lincoln (a cottager), sent three splendid samples of Sutton's Satisfaction, Reading Russet and Windsor Castle Potatoes, well meriting the cultural award given.

Seedling Melons were shown by Mr. Bishop, Westley Hall, Bury St. Edmunds, Mr. Empson, Amptill House, Mr. Ward, Longford Castle, and Mr. Warren, Gloucester Nursery, Hampton. Mr. Wythes sent Melon Beauty of Syon to test its quality as a late forcing variety, it having been certificated in 1892.

Grapes were shown largely, but the greatest interest was centred in the open-air kinds, a very nice lot having been sent from Chiswick Gardens, the berries good and the quality excellent. Chasselas Noir was fine, also Chasselas Rose and Gamin Noir. A very fine bunch of Black Monukka was also staged and of splendid flavour. Mr. Will Taylor, Hampton, sent Grape Olga de Wurtemberg from open walls much like Gamin Noir in flavour. Mr. Bradshaw, Hillsborough Castle, Co. Down, Ireland, sent his new seedling Grape Lady Downshire, the berries being oval and amber-coloured, but not in good condition. Mr. Empson staged a new seedling Grape, Mrs. Wingfield, not unlike Madresfield Court, but in favour a Gros Colman. This was asked to be sent again early in the year. A very fine lot of Red Gravenstein came from Nova Scotia, through Messrs. Nothard and Lowe, Tootley Street, London. These were sent as distinct from the old Gravenstein, being more highly coloured, the old kind also being staged. Mr. Palmer, Andover, sent a seedling from Red Quarrenden, similar, but much later, and of excellent quality. This was desired to be sent later to test keeping.

Seedling Apples were also sent by Mr. Thomas, the Royal Gardens, Frogmore; Mr. Wallas, Leighton Buzzard; and Messrs. Paul, Cheshunt. Mr. Mills, Southampton, sent Blenheim Orange Pippin, a bright red-skinned fruit: this had been treated with chemicals to obtain colour. Messrs. Spooner, Hounslow, sent Apple The Baron, but not equal to older kinds as regards quality. Mr. Hill, Tring Park, Tring, sent very fine fruits of Pear Doyenné du Comice grown on a south wall. Mr. McIndoe, Hutton Hall, Guisborough, sent a new seedling Pear named Charles Ernest. Though of fine appearance, it lacked quality.

A lecture on "Nut Culture" was given by Mr. J. O. Cooper. Unfortunately, the paper was, to our mind, rather marred by botanical information which savoured too much of the ordinary treatise, but Mr. Cooper told his hearers some useful facts. He mentioned that the wood of the common Hazel was used in many ways, for cabinet-making, toys, whip-handles, &c., and those rods from dry ground were most durable. The Hazel would make a good hedge, only Nut gatherers would destroy it by their depredations. It forms an excellent covert for birds, and by its autumn tints adds greatly to the beauty of the landscape. All cultivated Nuts are called Filberts, and the large cultivated Nut was unquestionably an introduction, but at what date is not

known, although doubtless first introduced into Kent, where the Nut is most largely grown.

The Nut is propagated by layers, suckers, grafting, and from seed. It does not come true from seed, a slow process too, and is best from layers, a period of twelve months being required for the layers to root well. The tree may be grown on the borders of plantations, in open spots, or in plots when grown for market. The ground must be well drained and the trees put 12 feet from row to row, or sometimes growers place them at 24 feet with a row of Apple or other trees between. The lecturer mentioned various other ways of planting, as in squares. A rich, dry loam, well worked, and with a stony or rocky bottom formed the best soil. A very important point is to remove all suckers from the trees, and a great mistake, too, is to let weeds grow on the surface of the soil. The return of Nuts on a plantation of 8½ acres of forty-five years' growth was 2 tons as the maximum and 2½ cwt. as the minimum. This was in Kent, with Apples and Damsons grown between. The lecturer mentioned, however, that the Damson was not suitable for such culture, because it robs the soil of nutriment, is a prey to green-fly, and the crop does not pay. Mr. Cooper mentioned as especially suitable varieties Webb's Prize Cob, a hardy, prolific Nut and the Nut of the future, Daveyanum and the Duke of Edinburgh.

He also made interesting remarks about the many enemies of the Nut, the nuthatch, squirrel, field mouse, &c. Unfortunately, we lost much of the lecture through the bad acoustic properties of the hall. It is seldom possible to hear a lecture well.

## NOTES OF THE WEEK.

**Polygonum Brunonis** is one of the best rock plants to give bright colour in the late autumn days, but we never saw so much of it as at Cragside, where there are groups in several aspects, each covering many square yards of rocky ground. It is here most luxuriant and effective in colour with its thousands of erect spikes of red flowers.

A pretty *Ipomæa* trained to the roof of one of the glasshouses in the gardens at Callaly Castle is flowering well. The plant was sent from the Bermudas and looks uncommonly like the old *I. Leari*, except that it has large lobed, Vine-like leaves, that are not exactly like those of *I. Leari*. Its flowers are of a pale blue outside, but inside they are of an exquisitely rich shade of deep blue, with a red vein which makes each division of the flower specially prominent.

**Mina lobata** would be of little use for outside walls in northern gardens except for those favourably situated, but at Lilburn Tower it is grown in the conservatory and trails about prettily along the front lights, hanging in graceful festoons. It is a plant that always attracts notice when blooming by reason of its singularly forked flower-spikes and the contrasting hues of its rich red buds and creamy yellow blossoms. It is treated as an annual and the plants are grown in pots.

**Delphiniums flowering twice in a season.**—An incident of this exceptional summer is the sight of a bed of these fine hardy plants in bloom during October. They had borne their usual crop of extra strong spikes, and the great height to which the clumps had grown caused them to get much blown about by wind; this induced the owner to cut them down when the flowers were over, with the result that another display, if not equal to the first, is, nevertheless, a very fine one.—S.

**The Sweet Brier flowering in October.**—It is not often that autumnal flowers are seen upon our native wild Roses, but the Sweet Brier has been blooming profusely of late, doubtless a result of the phenomenal weather. In the early days of the present month we saw a long hedge of it studded with many fresh pink blooms, the branches as well heavily laden with the scarlet hedges from the first flower crop. But for these,

the appearance of the bushes was more suggestive of June than October, as there were many flowers open.

**An old Peach tree and its crop.**—I herewith send you a photograph of a Peach tree in my garden which has borne a wonderfully profuse and good crop this summer. The tree had upon it over 370 fully-developed Peaches, many having been picked before the fruit was counted or the enclosed photograph taken. The tree, which is of the Barrington variety, was planted eighteen years ago against a wall facing almost due west in a garden on a rather steep slope on the top of Widcombe Hill, Bath, and, curiously, the trunk of this tree is almost entirely dead. My gardener had not expected the tree to last through the season on account of this rotten state, and therefore did not take the trouble to relieve it of any of its abundant promise.—V. W., Bath.

**Desfontainea spinosa.**—One would hardly expect to find this beautiful shrub growing and flowering freely in the heart of Northumberland. We have just seen several fine healthy bushes studded with flowers in Lord Armstrong's delightful garden at Cragside. This shrub, however, is not hardy here, but it receives full exposure throughout the summer and autumn months. The bushes are growing in a border in front of a wall, against which a lean-to glass erection has been built, but all the glass-lights are taken away during summer. This and several other equally beautiful half-hardy plants are thus grown and flowered to perfection, and they worthily deserve such careful attention. No shrub of the present time is so showy in blossom. Some of the finer bushes were 5 feet in height, a dense mass of spiny Holly-like leaves, which make a fine setting for the large tubular red and yellow flowers.

**The weather in West Herts.**—A week of changeable weather. On the 10th the temperature in the shade at no time rose above 52°, whereas two days afterwards the highest reading was 60°. Again, on the night preceding the 11th the thermometer on the lawn showed 4° of frost, but during the following night it never fell lower than 42°. Both at 1 foot and 2 feet deep the temperature of the soil now stands at 54°, and at the former depth is rather more than 3° above the October average. There were four fine days during the week, but the fall of rain since the beginning of the month has been heavy even for October, amounting altogether to nearly 2½ inches.—E. M., Berkhamsted.

**Names of plants.**—A. N.—Grass: *Melica uniflora*.—*Alpine*.—1, *Clerodendron trichotomum*; 2, *Buddleia Lindleyana*; 3, *Cistus albidus*; 4, *Caryopteris mastacanthus*; 5, *Cistus*, too poor to name.—*Ignorant*.—2, *Tolpis barbata*; 4, *Sisymbrium Millefolium*.—*P. E.*.—1, *Oncidium incurvum*; 2, *Epidendrum prismatocarpum*; 3, too shrivelled; 4, *Ocimum Forbesi*.—*L. H. S.*.—1, *Adiantum pedatum*; 2, *Nephridium molle*; 3, *Selaginella Martensi*; 4, *Selaginella casia*.—*W. Eastwood*.—A remarkably fine spotted form of *Odontoglossum crispum*. You ought to show it to the Orchid committee of the R.H.S.

**Names of fruit.**—A. B.—1, Egg, or White Paradise; 2, Golden Noble; 3, London Pippin.—*J. B.*—Probably Sturmer Pippin.—*H. T. Balfour*.—Norfolk Beaufin.—*J. D. C.*—1, Hawthornden; 2, not recognised; 3, Norfolk Beaufin; 4, small Lane's Prince Albert; 5, not recognised.—*H. W.*.—1, Marie Louise; 2, Louise Bonne; 3, Duchesne d'Angoulême; 4, Glou Moreau; 5, Uvedale's St. Germain; 6, Hollandbury; 7, Hawthornden; 8, Cout Pendu Plat; 9, Hanwell Souring; 10, Gloria Mundi; 11, Blenheim Orange; 12, not sure of.—*W. E. Anderson*.—1, 3, 5, Pearn's Pippin; 2, Sturmer; 4, Royal Russet; 6, not recognised; 7, Emperor Alexander; 8, Blenheim; 9, Pear Eyewood; 10, Pear Van Mons Leon Leclerc; 11, not recognised; 12, Pear Souvenir du Congrès; 13, Pear Easter Beurré; 14, Hanwell Souring; 15, Hoary Morning; 16, Pear Hessele; 17, Sturmer; 18, Northern Greening; 19, Pear Beurré Rance.—*T. A. D.*—Blenheim Orange.—*R. C. Coode*.—Apple Golden Noble.—*W. Lisney*.—Nouvelle Fulvie.—*A. R. Walfar*.—1, not recognised; 2, Catshead; 3, Lane's Prince Albert.

No. 1249. SATURDAY, October 26, 1895. Vol. XLVIII.

"This is an Art  
Which does mend Nature; change it rather; but  
THE ART ITSELF IS NATURE."—*Shakespeare*.

## ORCHARD AND FRUIT GARDEN.

## STRAWBERRY GROWING ON ALNWICK MOOR.

A LARGE tract of exposed land on the outskirts of the town of Alnwick is divided up into lots and vested in the working-men freeholders of the town, who are each entitled to 1 acre. Strawberries having been found to do well, the growth of this fruit is becoming quite an important industry. One of the largest growers is Mr. Rickaby, who now has about 4 acres of ground entirely cropped with Strawberries, as, in addition to his own freehold, he rents the adjoining plots of others who prefer to let them. We lately had the pleasure of inspecting these Strawberry beds in the company of their owner, who, although quite an amateur in gardening matters, and whose lines of culture are altogether different from those pursued in the south of England, has certainly met with remarkable success, so much so, that the area devoted to Strawberries is being extended each year, other freeholders following his example. The place is fully exposed to the north-east winds, which sweep across the tract direct from the sea with nothing intervening in the few miles to break their force. In consequence of this the Strawberries are late, and their backwardness is without a doubt a contributory cause to the profitableness of the undertaking, as they ripen when the southern supplies are nearly or entirely over, and find a ready market in Newcastle, from which place considerable quantities of the fruit are sent further south. Instead of confining the plants to rows, as is generally done, they are here allowed to run together and entirely cover the ground. Mr. Rickaby maintains that in this way the plants shelter one another and do much better than when each is restricted to an isolated tuft. The soil is fairly stiff and suits Strawberries well, although it is shallow. Some of the best beds we saw were on the site of an old brick field, and there is a good quantity of burnt earth incorporated with the surface soil, which suits the plants. Deep cultivation, however, is essential previous to planting, and the ground is trenched up fully two spits deep. If the ground has been well prepared in this way the beds will stand a long time provided there is a little surface feeding each year. We saw some beds that were in their eighth year, and they were a perfect sheet of deep green leaves without an inch of bare ground or a weed visible. The crops from these beds had been as good this year as at any time since the plants were put out. New beds are formed in the spring of the year, so that the plants may have the entire season before them in which to establish themselves. The plants are put out thickly in the rows, which are about 2 feet apart. Plants that were put out only this spring had already nearly filled the intervening spaces with rooted runners. The varieties at present chiefly grown are the old Vicomtesse, here called Garibaldi, Marshal MacMahon, which Mr. Rickaby finds the best of all in that district, President and Sir Joseph Paxton. Noble has been tried, but did not succeed, and we saw a fine batch of Royal Sovereign just received to test next year. The latest kinds that are

grown in the south do not come to perfection, as, for example, Latest of All and Elton Pine. Another good grower on a smaller scale, and who first informed us of the existence of these Strawberry gardens, is Mr. Purvis. Some of his plants of this season's planting had made a very fine growth. He had Aberdeen Favourite on trial, and was favourably impressed with it.

**Yellows in Peach trees.**—This is a malady too well known amongst Peach growers, and a source of much disappointment, apparently quite healthy trees suddenly turning from a healthy green to a sickly yellow shade. Some soils seem to favour the disease more than others, the worst cases I have met with having been on strong soils retentive of moisture. In such the roots of the current year do not mature in autumn, especially should such be dull and sunless, and the effect is seen the following summer. Biennial, or at the most triennial, lifting of the roots is the only means in such cases of keeping the yellows in check, adding a large percentage of old mortar rubble, charcoal, or the sweepings of walks and drives, raising the soil also above the ordinary level and not covering the roots more than 3 inches deep. If this is done, say in October or during the early part of November, according to the varieties, just when the foliage is assuming a yellow tinge, and a mulching of leaf-mould or old Mushroom bed manure applied to protect the newly-disturbed roots from frost, a more healthy and better coloured growth will generally follow in spring. A little soot mixed with the soil is good in cases of yellows. When trees are replanted thus shallow, a good mulch of manure ought to be placed over the surface the following spring and occasional copious waterings given, or drought will be liable to affect them, and the trees consequently go from bad to worse. Some varieties of Peaches and Nectarines, notably Hale's Early and Lord Napier, are much more subject to attacks of the yellows than others, and I believe that, owing to the increased demand for trees now-a-days, unsuitable stocks are often employed, as it is well known that the stock that suits one Peach or Nectarine is often unsuitable for others. My advice is always to plant on stations so as to prevent the descent of strong tap roots, and in strong soils raise the borders, use plenty of correctives, lift every third year, and in order to counteract the evils of drought, mulch well and feed liberally.—J. CRAWFORD.

**Salway Peach.**—This old yellow-fleshed Peach is seldom met with now-a-days, but it is well worth growing on the back wall of a cool orchard house to ripen in October. It is naturally so very late that, even in Berkshire and under the influence of an average summer's sun, it is generally the beginning of November before it is quite ripe. If given the shelter of a cool house, the flavour is much improved; indeed, is preferable to that of some of the more popular late sorts, such as Lord Palmerston. A well-ripened fruit of Salway is very handsome, the mixed colours of yellow and bronzy red giving it an attractive appearance. Salway generally sets a fair crop of fruit, as, being later in coming into flower, it is not subject to so many cutting winds as the earlier varieties. All things considered, I consider it to be well worth a place in a late house if room can be spared.—J. C.

**Good late Peaches.**—There is a very gratifying improvement going on annually in outdoor Peach culture as compared with that of a dozen or more years ago. No doubt bad seasons accounted for some of the failures, but I think the system of cropping the borders with vegetables almost close up to the trees was one of the causes of non-success, especially with the later sorts, which were robbed by the crops, and frequently had their roots disturbed by lifting whatever was planted on the borders at a season when the trees and fruit required all the assistance they could obtain. By allowing more ground for the trees to root in undisturbed and a more liberal diet, with other good cultural attention, magnificent fruit

is produced that will equal that grown under glass. Golden Eagle is a particularly fine variety for late supplies either under glass or outside, ripening well and acquiring a beautiful golden hue, which has a telling effect both on the dessert and exhibition table. The flavour is also excellent as compared with that of some of the late sorts. Princess of Wales attains a large size both under glass and in the open, the pale colour of the fruit on one side with the delicate red flush on the other giving this Peach a very handsome appearance. Like Golden Eagle, it is a vigorous grower and bears freely. Walburton Admirable is a grand late Peach in most districts where this fruit succeeds on the open walls, but in some few instances I have known it to be unsatisfactory, ripening indifferently, though other late sorts on the same wall did well. Where it answers it well deserves a place, as the tree is very prolific and the fruit large, of high colour, and good flavour. Another variety not so late as the three sorts named is the old Bellegarde. Magnificent crops of large, deeply-coloured and rich flavoured fruit are borne on warm walls, and in my estimation it is one of the most reliable late Peaches grown. Of late, many complaints have been raised as to the low figures realised by early and midseason Peaches, and it is probable that more attention will be paid to the later sorts, as being more profitable. At the end of September and early in October fairly good fruit of Golden Eagle and Princess of Wales realised 9s. per dozen, and the fruiterer would no doubt charge double that figure for the same Peaches.—W. G. C.

**Coarse Pears.**—In the Pear classes at exhibitions, especially those connected with the R.H.S., it would be well to have a class for quality alone. There is no merit in growing Pears to a large size. Anything that can be got big seems now to be the order of the day. These big Pears are misleading to the general public, and exhibitors can hardly be blamed, as they naturally show what are likely to please the judges, well knowing that if they only selected for table quality they would not find a place in the prize list, let alone take the leading prize. I wonder how many of these big, coarse Pears find their way to the grower's employer's table. Not till there are classes set apart for quality alone will there be any improvement. A big, coarse Pear is the worst of all fruits, big fruits of other kinds not showing such a difference in quality.—Y. A. H.

## PACKING PEACHES.

I WAS pleased to see the comments of "S. W. F." (p. 274) on the recent fruit packing at the Crystal Palace show, and especially that relating to Peaches. The reason also why the Peaches packed in Moss got into the prize list it would be well to know, as Moss is not at all a desirable material for successful Peach packing. The many boxes which I have seen of Moss-packed Peaches which had been sent to Covent Garden Market had anything but an enticing look. The reason probably of there not being an entry packed with paper shavings is on account of the difficulty of securing this material in a condition suitable for the purpose. I have used a large quantity for packing Peaches for Covent Garden Market, and wish for nothing better, only it is so difficult to get a regular supply. For packing during very hot weather paper shavings are the best, the fruits lying cooler than when wood-wool is used. My preference for soft tissue shavings does not, however, lead me to speak in disparagement of wood-wool, as this is an excellent substitute, being wonderfully cheap and easily procurable, the fruits turning out very clean. In these days of further enlightenment on fruit culture and packing one need wonder why anyone should use short dried grass for Peach packing, as this is as bad as it can well be.

It is possible to command excellent prices in Covent Garden Market for sound and good Peaches well packed; so growers, if they produce good fruit and packed so that it reaches the sales-

man in fine condition, need not fear being outdone by the foreigner, as was prognosticated a year or two back. My last consignment of Peaches this season—and these Sea Eagle from the open wall—fetched 18s. per dozen. This, I may say, is the best price I have ever had for open-air Peaches. Eight shillings, ten shillings and twelve shillings are, however, common prices. I quite expected after the published reports of the large Peach crops generally that prices would rule low, but they have not, as results have proved. Of course the fruits have been well developed and highly coloured. If only six shillings or eight shillings per dozen on the average were received for open-air Peaches, there would be an excellent margin of profit.

Y. A. H.

**Apple Mère de Menage.**—This is one of the best Apples that I know to plant as a standard, as it is a vigorous grower, quickly forming a large head, and will commence to bear in a few years from time of planting. In about twelve years the trees produce heavy crops of large Apples of brilliant colour that can always be sold at fair prices, or they can be stored for several months for private use. Another advantage, as compared with other varieties, is that the fruit is not blown down by rough winds to any serious extent. During the recent gales a number of young standard trees heavily cropped scarcely lost any fruit, and they are now a picture, the bold red fruit being conspicuous for a long distance. Grown as a bush or espalier tree, Mère de Menage produces fair crops of fine fruit, but it is not one that I should plant with a view to profit, as there are so many others that are far more prolific in a restricted form of growth. If exhibition fruit is required, the finest fruit is borne by these restricted trees. Some of the largest and best formed Mère de Menage I ever had were grown on a small wall tree, the Apples acquiring a delicate bloom never seen on fruit from trees in the open, but when I exhibited them in competition I was disqualified, as the judges considered they had been grown under glass. Since then, if I have staged any Apples grown on wall trees, I have stated the same on the label bearing the name of the variety.—W. R. H.

**Late flowering of Apples.**—At Ham House gardens Mr. Sage drew my attention recently to the vagaries of Apple trees in producing abnormal bloom. A Worcester Pearmain tree that was transplanted last winter had produced fruits that were then about one-third developed, a Yellow Ingestre that had not been transplanted had embryo fruits set, and in two other cases clusters of flowers were numerous on the trees. These clusters and fruits were in all cases on the point or extreme buds. A few varieties of Apples fruit from these points naturally, and such ones may next year be so far fruitless where point buds have this autumn flowered. Probably very little harm generally is done, especially that spur-buds seem in no way affected. The case, however, seems to evidence undoubted structural differences between spur and point buds.—R. D.

**The heaviest Apples.**—I think it is a decided mistake and waste of money to offer prizes for the heaviest Apples, for I cannot see that it promotes good culture or advances the cause for which the societies are formed. In fact, I think it does positive harm, as it perpetuates the growth of varieties that would otherwise be discarded altogether and that have nothing but size to commend them. I find on looking over my Apples that the heaviest are those borne by Gloria Mundi, of which I have two trees, that are easily distinguishable from all other varieties by coarse, rampant growth and foliage of great size. During the last ten years these trees have never borne anything like a crop, but they almost invariably have a thin sprinkling of fruit that beats in weight that of the other sorts that do carry crops. Some of the largest are between 17 oz. and 18 oz. in weight, and if there were good prizes offered in this locality for the heaviest dish of Apples it might answer my purpose to let them

remain. As it is, the trees will be headed down directly the leaves drop and re-grafted with some good all-round sort. I am a great admirer of large Apples, but I want them to have other good qualities as well.—JAMES GROOM, Gosport.

**Apple Kerry Pippin.**—The rage for size and colour seems to be so much on the increase, that smaller and less attractive Apples like Kerry Pippin are in danger of being almost neglected. For private use there is no comparison between, say, Worcester Pearmain and Kerry Pippin; the former is unquestionably the more valuable variety for sale, but the latter is infinitely superior in flavour, and is just the size most people like for dessert. As a bush tree this variety is very prolific, rarely failing to bear a crop, and on a light, warm soil the fruit attains a lovely colour on the sunny side. Very few varieties of Apples will equal this for flavour in its season—September, and any intending planters will do well to add this delicious little Apple to their collection.—W. G. C.

**Apple Hornead's Pearmain.**—For a number of years I have been watching a standard tree of this variety growing in the garden of one of my labourers. This garden runs down to a river bank, and the tree is not more than half a dozen yards from the stream, yet in spite of this almost every year it is heavily laden with fruit, frequently carrying a big crop when other trees on higher ground are a failure. Such a fact would appear to upset the theory that high ground above the fog line is most suitable for Apple culture. While always advising orchards to be situated on high land, I must acknowledge to having been puzzled to account for the good crops produced on a tree that has to be enveloped in fogs almost every morning while in bloom. It may be that Hornead's Pearmain is specially suited for growing in low-lying positions, or is it that the fog acts as a protection to the blooms, thereby saving them from injury by spring frosts? However, apart from this question, Hornead's Pearmain is a valuable Apple for spring use, as it keeps sound up to the end of April, and is an excellent cooking sort as well as a fair dessert fruit. In whatever form the trees are grown they are remarkably prolific. In seasons when the Apple crop is light the fruit sells at good prices, but the greenish colour is against it in seasons like the present one when Apples are plentiful.—R. H.

#### OUTDOOR GRAPES.

CAN Mr. Cornhill give any information respecting the character of the Vine from which come the Valencia Raisins of commerce? Is it of such hardy nature as to warrant any attempt to grow it outdoors in Surrey? I have found a large number of seedling plants to come up on a little border under a wood fence on the warm side of my back yard here, evidently from pips of the Valencia Raisin; and as where other things thrive so poorly they seem to thrive so well, I am proposing to presently plant a few of the strongest close to the boards, adding a little manure to the poor soil so as to encourage growth. I cannot say how long the pips may have lain on the ground before germinating; possibly several months. The yard is a very warm one during the summer up to 4 o'clock, but later is greatly shaded by the house. Still, the fence of close boards 6 feet in height has a south aspect. Even if these Vines do not in time produce fruit, at least they may form a pleasant green covering to close tarred boards, and even in the autumn give some charming colour. To furnish leaf colour on walls or fences I have found none better than Madresfield Court, and even the berries have come of good size and fairly well coloured on a south wall in Middlesex. Obviously for outdoor culture to secure nice, sweet, edible Grapes we need not only hardy, but precocious varieties. The common fault of most outdoor Grapes is that, because of the cool conditions under which grown, the bunches become solid clusters, keeping the berries very small and imperfectly developed. Could we but find some varieties that would give

fairly loose bunches which needed no thinning, then the gain would be considerable if the berries finished well. The best for this purpose I remember, and it used to fruit admirably on a south wall forty-five years ago in Hampshire, was the Dutch Sweetwater, the bunches rather short, but the berries of good size and not thickly set. It would be folly to suppose that thinning outdoor Grapes would repay for the labour required, especially when we can purchase fairly good home-grown house Grapes at 1s. per lb. and capital Spanish Grapes at 6d. per lb. I have observed that Mr. Fenn still grows both Royal Mascadine and Esperione Grapes on the warm end of his farmhouse at Sulhampstead, partly under glass and partly exposed on the open wall, but then he grows only for wine production, and it would seem as if acidity was in that case as important an element as saccharine. There are, however, many secluded or rural places in the kingdom, and in its southern part especially, where shop Grapes, if ever so good and cheap, are not obtainable. There, too, may be found plenty of house or cottage walls on which with proper culture and good varieties fair Grapes may be produced in warm seasons that would be a long way better than none at all. No doubt in the majority of cases Vines are grown outdoors more for the sake of summer ornament than for fruit production. Most likely, too, Apricots and Pears on warm aspects are more profitable and satisfactory croppers. Still, something may be granted to the picturesque, and certainly few things tend to that feature so fully as do Vines on houses and cottages in rural districts.

A. D.

#### PLANTING FRUIT TREES.

EVERYONE who has experience in planting fruit trees is well aware of the great advantage gained by early planting, say from the end of October to the end of November, provided the land is clean and ready to receive the trees. The importance of having all necessary preparations for planting made beforehand can scarcely be over-estimated in the future. The land is often badly drained, foul, or unsuited for fruit culture. Again, aspect is not sufficiently studied in many instances. I could point out a plantation where a large sum of money has been expended in working the land, draining, fencing from rabbits, and planting with fine trees, but the whole will probably be a dead loss to the proprietor, because the aspect is due north, with a sharp slope of the land in that direction. Many landowners and others are planting fruit trees with a view to profit, and it cannot be too strongly pointed out that if they wish to obtain a good interest on their outlay, the conditions must be favourable for the success of the trees, and all cultural details be of the best and most practical description. It is sheer folly to plant good varieties of fruit trees on land that will not produce decent timber, yet this is occasionally done, and then the planter raises a lamentation that this climate is unsuitable, and fruit production overdone in this country, as the supply greatly exceeds the demand, further adding that foreign competition is ruining the industry. No doubt the low prices that have prevailed this season for fruit will be quoted as a proof of the same, but it is only a case of the grower making up his mind to grow only the best sorts on suitable land with proper attention, and far different returns will be realised than it is possible for ordinary cultivators to obtain. This brings another important feature before intending planters, viz., to avoid planting any great quantity of early sorts of Apples, for the reason that in prolific seasons the supply of the same is fully equal to all demands, and that supply is likely to be further added to in the near future by the trees already planted as they increase in size and bearing powers. By planting such varieties as Lane's Prince Albert, Bramley's Seedling, Dumelow's Seedling where it succeeds, and other sorts of that class which can be stored and kept until late in the spring, when both home and foreign supplies are practically exhausted, high prices

then can be secured for sound, well-grown fruit. The only Apples that I have made really good prices of early this season are White Transparent and Worcester Pearmain; in spite of the glut these sold at high figures, and it may be worth while planting these two sorts for some time yet. The former is valuable for its earliness—end of July—good size, attractive appearance, and freedom in cropping. The chief recommendation of the latter is the high colour and prolific habit, causing it to sell well in manufacturing centres. For private use the case is different, as early, mid-season, and late Apples are a necessity, and the choice of excellent varieties is now so good, that with a proper fruit room there is no difficulty in ordinary seasons in having a supply of good fruit all the year round. Amongst reliable sorts the following have proved good, especially when grown in bush form: *Dessert*—Beauty of Bath, Devonshire Quarrenden, Lady Sudeley, Kerry Pippin, American Mother, Cox's Orange Pippin, Ribston Pippin, Egremont Russet, Roundway Magnum Bonum, Baumann's Red Reinette, Allen's Everlasting, and Sturmer Pippin. *Cooking*—White Transparent, Duchess of Oldenburg, Lord Suffield, Ecklinville Seedling, Golden Spire, New Hawthornden, Warner's King, Bismarck, Lane's Prince Albert, Bramley's Seedling, Alfriston, and Dumelow's Seedling. This list has enabled me to provide good fruit all the year round for my employer's table, but it might possibly need some little alteration to suit different districts, as local influences affect varieties to some extent.

Turning to Plums, we again find too many varieties grown by market men. According to my experience, Early Prolific and Victoria are still the most profitable, but it is a question if the latter will be able to maintain its position, owing to such vast numbers being planted. It is very probable that Monarch and Grand Duke will prove more remunerative, as they are both strong growers, free bearers, the fruit large, heavy, and of a pleasing colour. Another good feature of both varieties is that the trees appear to crop equally well as cordons, bushes, or standards. Archduke is another promising late Plum that has answered well with me for three years, and one that I should include in making a new plantation. Amongst varieties of Plums for a private garden in addition to those already named I would include Kirke's, Jefferson, Coe's Golden Drop, Denniston's Superb Gage, and Old Green Gage.

In Pears for market, only those sorts that attain a good size and handsome appearance will fetch top prices; they may be of inferior flavour to smaller and less attractive varieties, but as money is the object, flavour must take a second place to appearance. One of the best quality handsome Pears is Durondeau, and the tree crops well most seasons whether in bush or other form, the fruit always realising a satisfactory price. Clapp's Favourite is another handsome large Pear, of moderate quality, and selling well in its season—August. Young standard trees have borne very heavy crops for several years. Louise Bonne of Jersey should be grown by all Pear lovers, as its flavour is delicious, the fruit of fair size and lovely colour, and the tree remarkably prolific in all forms. Pitmaston Duchess is well known for its size and value for market. On a deep and good soil this variety produces very heavy fruit in large quantities both on bush and standard trees, but on high trees much of the fruit is marked by winds blowing it against surrounding branches, or is knocked down and considerably bruised. The larger the fruit, the more danger there is of injury from gales with both Pears and Apples. Beurré Hardy and Marie Louise d'Uccle are both good vigorous growers and very prolific varieties, producing large fruit that commands a reasonable value in the market.

A longer list of names might be given, but it is always advisable, in starting to plant fruit trees for market, first to discover which sorts answer best in the district, and then to only choose a very limited quantity of varieties of each kind,

thus enabling the grower to place repeated supplies of the same upon the market in bulk.

W. G. C.

### PRUNING RASPBERRY CANES.

I HAVE been somewhat surprised of late at some of the views prominently advanced on the best mode of pruning Raspberry canes. To prevent confusion it is needful to make it clear that here I chiefly limit my remarks to the pruning or cutting back of summer-bearing Raspberries. There is a general agreement that the bearing wood of the current season can hardly be too soon cut back to the ground level so soon as the fruit and wood are fairly ripe. Early winter or autumn pruning is also generally preferred for autumn-bearing Raspberries. The pruning, to be perfectly efficient, consists in cutting back all growth to the ground line. Simple as this seems on paper, not a few fail to practise it in the garden or orchard, hence the common name of double-bearing Raspberries, which could never have originated or been conserved until this October had no previous years' canes been left to fruit in the early summer side by side with the usual summer-fruited Raspberries. To have the heaviest crops of autumn-bearing Raspberries no shoots should be allowed to fruit on the stools, only such as have been grown during the current season. The pruning of summer-bearing Raspberries has a threefold character; first, as we have seen, the shoots that have borne fruit should be cut down level with the ground as early as possible. The next point is the thinning of the current year's shoots. The fewer in reason left to a stool the stronger; hence the importance of early and severe thinning of the current year's canes. From three to five canes to a stool will mostly be found ample, though much depends on distance apart, character of soil and climate, modes of training, &c. The time of thinning the canes of summer-fruited Raspberries should begin in the days of suckerhood and be continued through the growing season, so when the dual season of maturity of fruit and wood arrives, no more nut-brown canes may be found than ample space may be found for around the stools or against the espalier rails. Now we reach the final pruning of Raspberry canes in the ordinary sense. This has consisted in the shortening back of the next year's fruiting canes to two-thirds, more or less, of their natural height from the ground. The mere height of Raspberry canes is of less moment than appears at first sight, and it is not my intention to lay down any hard and fast line as to heights of fruiting canes or distances between. The question deserving serious consideration is, whether to cut or not to cut the heads of summer-fruited Raspberry canes. For centuries cultivators have almost been unanimous in their advice to cut the heads off them with a firm hand. I do not say that use and wont make this or any other horticultural practice right. It furnishes, however, a strong presumption in its favour. Besides, general experience proves that few summer-bearing Raspberry canes can or will fruit from base to summit if left full length without cutting back. Even with severe pruning there is mostly a considerable proportion of the base of the cane that does not fruit. Suppose we cease cutting back the tops, we of necessity lengthen the run of barrenness or of inferior fruit from the base of the cane upwards. As neither Nature nor art can compel long unpruned Raspberry canes to fruit over their length, the next best course may consist in making a selection of the best part of the canes for fruiting. That part is seldom found at

the base, hence too hard cutting back would be a mistake. It is never found on the crown of summer fruiting Raspberries; therefore, to leave the cane intact is a more serious mistake still. Skilful cutting back forces the mid-portions of the canes to fruit, which is without doubt the best bearing wood and yields the most uniform samples. Besides, unless Raspberries are all to be trained in various ways or supported by trellises, fences, walls, or arches, they must be shortened or pruned back to keep their fruit from being soiled by stress of wind or weather.

Thus were the fruiting capacity of Raspberry canes of uniform quality throughout—which they are not—or had their crowns been as much superior as they are undoubtedly inferior to their centres in uniformity and potency of fertility, even then economy and convenience in growing, security and gathering would suggest an enforced shortening back or pruning.

Nature herself indeed furnishes the cultivator with his most vivid object-lesson in this direction. The late growths of the young canes lay them open to severe attacks of winter and spring frosts, and in nine seasons out of ten Nature prunes them back more or less severely. Hence most cultivators gave the final cutting back to their summer-fruited Raspberries late last February after they saw how much of the canes Nature had left safe and sound. Thus the last touch of the knife often becomes a dresser of frozen tissues and a short cut to healing and health. D. T. F.

**Outdoor Figs.**—I, like "Gwent" (page 235), wonder why the Fig is not more commonly grown in the open air. For the past seventeen years I have had a fair crop, but nothing like that of the present year, Brown Turkey being the best. I live within 100 yards of the sea, and the trees get all the western gales, which are very fierce. I never unnailed a branch and use no covering whatever. Of course, we do not get so much frost as you do in England.—JOHN A. COLTHORPE, *Summerville Gardens, Waterford.*

**Languishing Strawberries.**—Previous to the much desired rain a bed of Strawberries planted less than three years since was suffering so much from want of root moisture as to flag very badly under the tropical sunshine of September, notwithstanding the soil in which they are growing is unusually deep and in good condition as regards manure. The bed under notice is planted with four varieties. That which seemed to suffer most was Vicomtesse H. de Thury, while Laxton's Noble in the same border did not show any sign of languishing. To give the plants relief by watering was out of the question, for we had but a short supply for the daily routine of watering. Mulching would necessarily have been resorted to in the event of a continuance of such summer-like weather.—W. S.

**Peach Walburton Admirable.**—Unlike last season, when the quality of this fine Peach was very poor on account of the comparatively sunless season, this year, thanks to the fine autumn, it has been grand. We cannot hope of course for a succession of fine autumns, but, taking two seasons out of three on the average, we can rely upon its ripening up well. Anyone who can devote a space on a south wall to a tree, except in the more northern districts, should certainly plant this, the grandest of all late Peaches. Where Peaches will do well, several trees on a south wall both of this variety and Sea Eagle would prove a profitable investment. This year I could have sold any quantity at 10s. per dozen—not a bad price for open-air Peaches in such a generally fruitful year. With adequate feeding and thinning out to a fair distance apart, also exposing as much as possible to direct sunlight, the fruits individually swell up to a large size.—A. YOUNG.

## ORCHIDS.

## PAPHINIAS.

THE number of species in this genus is not large, but it comprises several very interesting and pretty Orchids that well repay the trouble needed in their cultivation. They are all natives of South America, and are small-growing pseudo-bulbous plants of a clustered habit of growth and epiphytal. Their culture is by no means difficult, the chief trouble being usually caused by insects, notably black and yellow thrips. It is too often thought that the presence of insects on plants of any kind denotes careless treatment, and though the plants may, by being badly grown, be predisposed to their attacks, there are some that seem to defy the best attention that can be bestowed on them. It is of course in the atmospheric treatment that we are most at a loss in the culture of these plants. No doubt if the same amount of air could be afforded them as they obtain naturally, there would be little cause for complaint, but this is for obvious reasons impossible. Heat they must have, also moisture in abundance, and it is quite out of the question, therefore, to open the ventilators when, for instance, a cold east wind may be blowing or the external temperature is very low. The air in the house then cannot be changed as often as necessary, and the foliage, not being so well hardened, becomes an easy prey to the insects. Fumigation, sponging and other remedial measures have then to be resorted to, but these, again, unfortunately weaken the plants, for it is the sensitive nature of the foliage that renders the plants so susceptible to injury from slight fluctuations of either heat or moisture. For the same reason Paphinias cannot endure bright sunlight, and heavy shading has to be applied during the summer. They all like a light position, however, and are best suspended as near the glass as possible. The best plants of Paphinia cristata I ever saw were grown in a house largely devoted to Phalaenopside, and which was in consequence very carefully looked after as regards ventilating and shading. Shallow pans, rafts or baskets may be used for these Orchids, according to convenience, but in whatever they are grown the drainage must have very careful attention. This is of the utmost importance, for the roots will simply rot wholesale in a sour or waterlogged compost. For the same reason this latter must be very carefully prepared and only the best material used. The best mixture consists of equal parts of peat fibre, chopped Sphagnum Moss, and mellow fibrous loam, the whole being kept in an open condition by a free admixture of potsherds and charcoal. If the best results are to be obtained, it will be necessary to repot about once in two years, and possibly a little of the surface will require renewing annually. By this means the roots will always have a little sweet and open compost to run in, and the freedom with which they extend under the circumstances is the best recommendation of the practice. The best time for repotting or top-dressing is the early spring, as at this season the plants begin to grow, and from this time until the flowers are past and the growth finished up they must have a liberal supply of water at the roots. Afterwards a little less will be needed, but they must at all times be kept moist. It is not unusual for

*P. CRISTATA* to grow, as it were, out of season and push new growths late in the autumn or winter, and when this occurs the water supply must be increased and the plants encouraged as much as possible. This species bears from two to four flowers upon a scape, each being nearly 3

inches across: the sepals and petals are broad at the base and pointed, cream-white in ground colour, which is hardly discernible on account of the number of spots and blotches of rich chocolate that cover it. The lip is very singular in form, the side lobes being claw-shaped, the front almost triangular, with a whitish downy point. It is an old and widely distributed species, having been introduced from Trinidad in 1834.

*P. GRANDIS* is a handsome kind, producing short scapes of about three very large and prettily marked flowers. The sepals and petals are whitish with large blotches of purple, the lip being similar to that of *P. cristata* in shape, with markings of deep purple and brown.

*P. RUGOSA* may be described as a small flowering and growing form of *cristata*, but the markings on the segments are dull purple. There are two varieties of this plant, the better one being that sometimes known as *P. rugosa Sanderiana*. H. R.

*Cattleya labiata* var. *Lowiae*.—In your issue of last week, in the list of awards of merit given by the R.H.S. on Tuesday last (page 308), we notice the omission of any reference to our white *Cattleya labiata* var. *Lowiae*, which received an award of merit.—H. LOW AND CO.

*Odontoglossum crispum* *Trianae*.—Although eclipsed in size by some of the best forms, this pretty variety has a distinct and effective appearance. A plant now in flower has but few spots on the sepals and petals, but these are of a reddish brown, quite different from the ordinary type. The petals have a faint line of rose colour on each, and the lip is broad and heavily spotted.

*Epidendrum ellipticum*.—This very free-blooming Orchid is deserving of more extended culture, for the flowers last in good condition and the plants bloom for five or six months out of the twelve. It is an erect growing species, with stems on the strongest plants as much as 5 feet high and clothed nearly to the base with leaves. The flowers are produced on pretty paniculate racemes from the apex of these and vary in colour from a soft pink to deep rose. *Epidendrum ellipticum* is a vigorous grower and must have a fairly large pot filled with peat and Moss, keeping it well supplied with water all the year round. It thrives best in a light sunny position in the *Cattleya* house.

*Dendrobium Jamesianum*.—Like others of the negro-hirsute section, this frequently gives us a few flowers in autumn, and they are very welcome just now. They are mostly produced from the old pseudo-bulbs and are not equal to the more naturally-produced blossoms that occur in spring. *D. Jamesianum* seems never entirely at rest; it is either flowering or growing all the year round, and should be treated accordingly. It thrives best in small pots only just large enough to take the plants easily, and a thin surfacing of compost is all that is required. It may be grown at the cooler end of the *Cattleya* house or with the *Odontoglossums*, great care being required to keep the growth free of insects if it is afforded more heat.

**Imported *Odontoglossum crispum*.**—Among a number of imported *Odontoglossum crispum* bought about five years there was a plant which when established showed distinct looking pale green leaves, *i.e.*, paler than those of *O. crispum* usually are. It has never flowered. The plant is in fine health; the bulbs have increased in size. I have tried keeping it near the glass, starving it, when the growth of the bulb is completed, without success. Can you suggest what is wrong? All my *Odontoglossums* grow well and flower well.—W.

\*\* It is rather difficult to know what to advise in your case, not knowing what your plant is, as several species have certain peculiarities about them in their manner of flowering. There are several species that are frequently imported with *O. crispum*, including the many forms of *O. gloriosum*, any of which it may turn out to be. *O. vexillarium*, too, comes from the same locality, but it is hardly possible to mistake this, or to

keep such a free-blooming Orchid so long without flowering it. A plan I have often tried successfully with cool Orchids that are slow to bloom is to allow rather more warmth when they commence to grow, getting the pseudo-bulbs finished up as quickly as possible, and then somewhat suddenly lowering the temperature again and keeping the plants dry at the root. They will then usually push flower-spikes, and as soon as these are seen the plants may be treated in the usual way. This is certainly worth a trial, and if by this means your plant is induced to bloom and you send a flower, more definite instructions as to its treatment can be given. It is useless drying the plant after the new growth is seen to be starting, as this only serves to weaken it without any advantage.—Ed.

***Odontoglossum Coradinei albidulum***—The flowers of this pretty variety are much lighter in colour than in the type, and quite equal in size and other respects. The very light primrose sepals and petals are narrow, with blotches and spots of brownish red, and the lip is nearly white, with a large blotch of brown. The typical plant is said to be a natural hybrid between one of the broad-petalled group and a narrower species, such as *O. gloriosum*, and is an autumn-flowering species of much value. It thrives well in small pots in peat and Moss at the warmest end of the *Odontoglossum* house, and should never be dried off. It is a native of New Grenada, and was introduced in 1872.

## ONCIDIUM FORBESI.

AMONG the many beautiful and free-blooming species contained in this favourite genus, few can compare with this, and certainly none can beat it at this season. The flowers are large and showy and produced freely upon the erect branching spikes. They are each upwards of 2 inches across, brownish in ground colour, with a narrow broken margin of bright yellow, the whole flower very bright and glossy in appearance. The pseudo-bulbs are oval-flattened and bear two or three light green leaves, from the axils of which the flower-spikes spring. *O. Forbesi* can hardly be called an easily-grown Orchid, as its tendency in many cases is to produce smaller pseudo-bulbs yearly until the plants are too weak to flower, and consequently become of little value. This, however, is more often than not the effect of over-flowering and of keeping the spikes too long upon the plant. When one compares the number and size of the blossoms with the pseudo-bulbs, it is surprising how they can be produced, let alone maintained week after week as they are in too many cases. The best position for *O. Forbesi* is in an intermediate temperature, between that of the *Cattleya* house and the *Odontoglossum* house, or if such an one is not at command, the plants should be arranged close to the door or a ventilator in the former. They may be grown either in pots, baskets, or on rafts, the principal requirements being a free, open compost, and not too much of it, and good drainage. The usual peat and Moss mixture is suitable for it, and the latter should be induced to grow freely about the bases of the pseudo-bulbs in summer, the roots delighting in the abundant moisture at the time the pseudo-bulbs are finishing. The spikes appear soon after the growth is complete and come quickly to maturity. At the first signs of distress of the pseudo-bulbs, or, better still, before, all the flowers must be cut, and the plants must then be allowed a long rest in a cool, airy house. Very little water will be needed through the winter, and if the bulbs shrivel a little from this cause no harm will be done, though this must not be carried to excess. The plants should be repotted just as they begin to grow, this being usually needed about once in three years, provided they are surface-dressed when this is seen to be necessary. *O. Forbesi* is a variable species, the best form being that known as *grandiflorum*, a large flowering and brilliantly coloured variety. It is a native of Brazil, whence it was introduced in 1837. R.

## FERNs.

## STRONG-GROWING TRICHOMANES.

By their general appearance as also by their mode of growth and the delicacy of the texture of their foliage, Trichomanes closely resemble Hymenophyllums, from which they differ mainly in their mode of fructification. The

though not truly pinnate, while in some other species again, and notably in *T. trichoidium*, the fronds are much-divided, slender, and flaccid, and their segments almost thread-like.

Trichomanes are found in tropical and temperate regions. The genus is represented in Europe by one solitary species (*T. radicans*), which is found wild in various parts of the United Kingdom. Only a few of the known

Trichomanes. but it may not be out of place to note here that whenever stone is used it is necessary that a little peat of a fibrous nature should be placed at its base to establish the plants. Trichomanes are usually propagated by division, although they may also be increased by seedlings, but that is a very slow and also very expensive process, as they require several years to produce plants of any

size. The only instance of their having been propagated from spores with which I am acquainted is that of a batch of seedlings, several hundred in number, which in 1886 were raised at Messrs. Veitch's nurseries at Chelsea, when the species reproduced itself without any noticeable deviation whatever from the normal form. These seedlings were produced from spores sown in 1882, and after four years' care and attention were only little plants in 2½-inch pots. Still, the experiment was very interesting, inasmuch as it proved that with a certain amount of patience Trichomanes may, like most other Ferns, be propagated from spores, especially when these can be sown immediately they are gathered.

Some very interesting Trichomanes may be found among the small and medium-sized ones, but the most decorative are those which I would term the strong-growing kinds, the most distinct of which are as follows:—

**T. ALATUM.**—This species, native of Brazil and the West Indies, and known also in gardens as *T. attenuatum*, is one of the most distinct of all. It is very variable in dimensions and hairiness, though its more or less broadly spear-shaped fronds, borne on tufted stalks 2 inches to 4 inches long and winged above, usually measure 3 inches to 12 inches in length and 1 inch to 3 inches in breadth. They are two or three times cleft nearly to their midrib, and provided with pinnae cut in the same way and lobes often again sharply toothed. Their delicately membranous texture and their very transparent pale green colour are shown to greatest advantage, and produce a most charming effect when the fronds are laden with condensed moisture. This species, which thrives best when established on a piece of Tree Fern stem, is hardly amenable to cold treatment, and prefers a temperature averaging from 45° to 50° in winter.

**T. APHIFOLIUM** is a beautiful species, native of the Philippine Islands and Polynesia, with fronds sometimes nearly 2 feet in length, including the dark, strong, hairy stalks. In general outline this plant somewhat resembles the better-known *T. maximum*, but it is of more graceful habit, and its fronds, which are produced from a closely-set crown, are much more finely divided and of a rich dark green colour.

**T. AURICULATUM.**—This is undoubtedly one of the most distinct Trichomanes in cultivation, as also one of the most beautiful on account of its peculiar climbing habit of growth and of the drooping character of its elegant fronds, which are almost stalkless, 6 inches to 12 inches long, 1½ inches to 2 inches broad, and twice divided nearly to the midrib. They are abundantly produced from strong, wide-creeping rhizomes and have the

*Trichomanes reniforme.* From a photograph by Miss Willmott.

genus comprises about 100 species, but many of these are of botanical interest only. In Trichomanes, as in Hymenophyllum, the fronds vary in shape and cutting, for while there are plants with fronds entire or slightly lobed, without a distinct central midrib and with veins radiating from the base in a fan-like manner, as in the New Zealand Kidney Fern (*T. reniforme*, here illustrated), others, such as the Killarney Fern (*T. radicans*, figured on p. 326), have their fronds more or less deeply cleft,

species are devoid of creeping rhizomes, but whenever these organs are apparent, they differ from those of Hymenophyllums by their hairy nature and the great tendency which they have to cling to stone or any other substance of a hard nature in the close proximity of which they may be growing.

As regards light, moisture, and ventilation, the treatment which was recommended for Hymenophyllums (see THE GARDEN, Sept. 21, p. 227) will be found equally suitable for the

stalk of their leafy portion slightly winged throughout or above only. Their pinnae, of a peculiar shape and obliquely wedge-shaped at the base, are exquisitely transparent. This species has a remarkably extensive habitat, as it is found in Japan, Formosa, Northern Hindostan, the Philippine Islands, Java and Guiana, where, according to Backhouse, it climbs on rocks and also to the tops of the loftiest trees. Although it may be successfully grown under cool treatment, this species succeeds best in a temperature of 45° to 50° in winter.

**T. EXSECTUM.**—Although of a very slender character and of a pendulous or drooping habit, this lovely species, native of Juan Fernandez Island and Southern Chili, where it is said to be found hanging from the roofs of damp caverns, deserves to be classed among the strong-growing kinds, for its exceedingly elegant fronds often attain 15 inches in length. They are very abundantly produced from a wide-creeping, slender rhizome, and are extremely delicate and membranous in texture, resembling thin, flat, much-branched or finely-divided pale green seaweed. Their segments are narrow, smooth, either simple or forked, and blunt at their extremity. This plant, which succeeds well under cool treatment, is equally at home on hard wood or on stone.

**T. GIANTIFLORUM.**—A strong growing species, native of Bourbon, Mauritius and the Fiji Islands, with fronds 18 inches to 24 inches long, including their stalks, and 6 inches to 9 inches broad. These are produced from a wide-creeping rhizome of a woolly nature, like that of the Killarney Fern, and finely cut, being four times divided almost to the rachis. Their segments, very narrow and distinctly flattened, are very transparent, notwithstanding their dark green colour and shining nature.

**T. KAUFERSSII.**—This very distinct species has broad, spear-shaped fronds 4 inches to 12 inches long and 1½ inches to 2 inches broad. They are produced from a strong wide-creeping rhizome of a woolly nature and are deeply cleft nearly to the broadly-winged rachis, the stalk of their leafy portion being densely and the surface of the segments slightly hairy. It is a native of the West Indies, Guiana and North Brazil, and requires stove temperature to grow freely.

**T. MAXIMUM.**—This species, which succeeds equally well on wood or on stone of a porous nature, is very handsome. Its erect, egg-shaped fronds, produced from a closely-set crown or very short rhizomes, each measure from 15 in. to 21 in. in length, including their stalks, and 6 inches to 9 inches in breadth. They are four times divided nearly to the midrib and their pinnules are very transparent. Although growing fairly well under cool treatment, this species, native of Java, Borneo and the Polynesian Islands, succeeds best in a temperature of 45° to 50° in winter.

**T. MEGALOTUM.**—This is probably one of the most beautiful of all Filmy Ferns in cultivation. It is a native of Java, where, according to Backhouse, it occurs on the mountains at elevations varying between 4000 feet and 7000 feet. Its lovely plumes of tufted fronds, produced from a close-growing crown, are, when fully developed, quite 2 feet high. They are spear-shaped and very finely divided, being cut into narrow, almost thread-like segments, some of which, like those of the better known *Toda superba*, stand forward and give the whole plant a very rich and soft appearance.

**T. PINNATUM.**—This species (also known in gardens as *T. floribundum*) is a native of Tropical America. It is as curious as it is beautiful, for its fronds, produced from an upright tufted rootstock, are conspicuously proliferous at their extremity. They are borne on strong, though flexible, naked or slightly hairy stalks, 3 inches to 12 inches long and of a wiry nature. Their leafy portion, only once divided to the rachis, is from 6 inches to 18 inches long and sometimes 12 inches broad, being furnished with very transparent pinnae 2 inches to 6 inches long, nearly 1 inch broad, sharply and finely toothed on their edges. They

terminate in a tail-like process, where they often produce a young plant which roots readily when touching the mossy ground or decaying vegetable matter, in which the plant thrives best in a temperature of 45° or 50°, or even higher in winter.

**T. PICTURUM.**—A magnificent species of erect and somewhat rigid habit, native of the West Indies, Peru and Brazil, and known also in gardens under the name of *T. anceps*. Its noble fronds, of a somewhat leathery texture, very dark green colour, and slightly hairy on their upper surface, are produced from an upright rootstock; they are 18 inches to 24 inches long with the stalks, 6 inches to 12 inches broad, and three or four times divided nearly to the midrib. Their lower pinnae (4 inches to 6 inches long) are divided into pinnules, which are again deeply cleft into narrow, sharp-toothed segments. It succeeds best in a temperature of 45° to 50°, or even higher in winter.

**T. RADICANS.**—This is the only representative of the genus found in a wild state in Europe, and is known in England under the popular name of Killarney Fern, from its having been found at the Powerscourt waterfall and at the waterfall above Turk Cottage, Killarney, exposed to the spray on shady banks and rocks. It has also been reported from various places in the counties of Cork, Kerry, Waterford, Wicklow, &c. I cannot find any record of its existence in Scotland, but E. J. Lowe, in his excellent work "Our Native Ferns," vol. ii., p. 448, states that it has been found growing luxuriantly in some abundance in various places, extending over several miles in Wales, but that the localities have been kept secret on account of the dread of its extermination by collectors. In the third edition of Ray's "Synopsis," published in 1724, it is first mentioned as a British Fern by Dillenius, who gives an illustration of it, and describes it as a "dwarf creeping Fern, with transparent and shining leaves and winged stems," and states that it was found by Mr. Richardson at the head of Elm Crag Well, at Bellbank, near Bingley, Yorkshire, in which locality it was also found in 1758 by Bolton, who then remarked that it was plentiful in that district. But it is of a very cosmopolitan character, as it is also a native of Spain, Teneriffe, the Canary Isles, Madeira, Mexico, Brazil, &c. Beddome, in his "Ferns of British India," gives an illustration (t. 181) of the plant as found on the Khasia Hills; Eaton, in his "Ferns of North America," gives an illustration of it and states that it is found in Alabama; while Lowe, in his "Ferns British and Exotic" (vol. viii., p. 43), states that it was observed by Swartz, Bancroft and Purdie in the woods in Jamaica; Radcli, Forbes, Macrae, Scouler, Gardner, Sinclair and Vautier report it from various parts of Brazil, and Colonel Hall found it in the forest of Esmeraldas, El Ecuador; and Dr. Hochstetter and Mr. H. C. Watson found it in the Azores at an elevation of from 2000 feet to 3000 feet above the level of the sea. The fronds of *T. radicans*, including their stalks, vary from 6 inches to 18 inches in length and from 2 inches to 6 inches in breadth. They are produced from a wide-creeping rhizome of a hairy nature, which has a particular liking to stone, to which it clings with great tenacity. They are three times deeply cleft to the rachis, which is narrowly winged, and their pinnae are again deeply cleft into conspicuously toothed segments, their texture, though transparent, being particularly firm.

The following are among the most distinct of the large-growing numerous forms of this very variable species:—

**T. R. ANDREWSEI.**—A variety originally found at Iveragh, Ireland, by Mr. W. Andrews, of Dublin. It is of normal dimensions and differs from the species in having narrower, more spear-shaped fronds, in their leaflets being more distant and distinct, and in the stalk being more elongated and less winged.

**T. R. CAMBRICUM.**—A Welsh variety, which differs from the species in the leafy portion of its handsome fronds being broadly triangular, and

in their pinnules being much more numerous and quite wedge-shaped at the base.

**T. R. DELATATUM.**—A plumose form, differing from the type, as also from all other known varieties, by its large, massive, very dark green fronds, and by its pinnules, which are much less divided than in the species and broadly winged.

**T. R. DISSECTUM.**—As regards size and form of frond, this is somewhat similar to *T. r. cambricum*, but the pinnules are cut again into narrow segments, which sometimes are wedge-shaped at the base, when the plant is called *cuneatum*.

**T. R. KUNZEANUM.**—In this variety, native of Brazil, the fronds, of a somewhat leathery texture, are 12 inches to 18 inches long, besides the stalks, which are scarcely, if at all, winged; the pinnae are distant, stalked and furnished with deeply cut pinnules, the lowest lobes of which are again cut into very long and narrow segments.

**T. R. LUSCHNATIANUM.**—A beautiful variety, also a native of Brazil, readily distinguished from all others through its narrower fronds, of nearly uniform breadth, being quite stalkless, the pinnae reaching to near the rhizome, and the leafy portion tapering to a narrow point.

The last two varieties are not so hardy as the others, and succeed best in a temperature of 45° to 50° in winter.

**T. RENIFORME.**—As will be seen from the illustration, this species, usually known as the Kidney Fern of New Zealand, is a plant of very peculiar habit. Its singular fronds, produced from naked rhizomes of a particularly wiry nature, are kidney-shaped and entire, with a deep notch at the base, and borne on naked, wiry, round stalks 4 inches to 8 inches long. The leafy portion is 2 inches to 4 inches broad and very transparent, though somewhat thick, with veins radiating from the base in a fan-like manner, and, when fertile, the spore masses are arranged in a very regular manner all round the outer edge of the fronds and disposed at the end of nearly every vein. This species succeeds equally well either on a Tree Fern stem or with its slender rhizomes running into soft sandstone broken into small pieces and mixed with rough, fibrous peat.

**T. SCANDENS.**—A lovely species, native of Jamaica and Mexico, where it is found growing on trees. Its elegant fronds, 6 inches to 18 inches long, are produced from a wide-creeping rhizome of a wiry nature, and borne on strong, erect, naked stalks 2 inches to 4 inches long. They are cut quite to the stalk, which sometimes is slightly winged and hairy; their pinnules are divided into segments, that are again cleft about half-way down, with the margins finely hairy.

**T. SUPERBUM.**—This beautiful species, also known in gardens under the name of *T. fimbriatum*, is a native of Trinidad and British Guiana, and a very distinct plant. Its broadly egg-shaped, erect fronds, borne on strong stalks 2 inches to 5 inches long, and winged nearly down to the base, are produced from a strong, wide-creeping rhizome. Their leafy portion, 4 inches to 9 inches long and 2 inches to 4 inches broad, has its lower pinnae divided more than half way to the stalk into oblong, toothed lobes. It delights in decaying vegetable matter and in a temperature of 45° to 50°, or higher in winter. S. G.

#### PROPAGATING FERNS.

At page 249 "H. P." mentions that I did not refer to *Asplenium* in my note on sowing Fern spores. It was an accidental omission, though I intended referring to the genus with regard to other modes of propagation. I quite agree with what "H. P." says with regard to the uncertainty of spores germinating. This is generally the case with those most prolific in bearing bulbs, while in some destitute of them seedlings are easily obtained, though *A. lucidum* is an exception to this. I also agree with "H. P." with regard to spores collected in the autumn germinating in the spring, as I should regard

them as new spores. Although instances similar to those mentioned by "H. P." have come under my notice, I consider it misleading to quote isolated cases, especially as I have had so many disappointments when sowing spores which had been kept more than a year or two.

With reference to propagating *Aspleniums*, a great number of these produce bulbils on the fronds from which young plants are easily established. In some instances it may be necessary to peg down the fronds on suitable material for the young plants to make some roots before removing them, but generally the smallest bulbils may be established by treating them like spores when first sown. In some sorts fair-sized plants may be established on the old fronds without any pegging down, and these will give little trouble. For those taken off when quite small I like to surface the pots with peat, chopped Sphagnum, and sand in equal parts, passing it through a fine sieve before using. A number of other Ferns may be propagated in the same way as the *Aspleniums*, though few are so prolific. The beautiful *Gymnogramma schizophylla gloriosa* is a remarkable example, being, as far as I am aware, the only one of the genus. One young plant from the extremity of each frond is generally obtained, though sometimes the side pinnae also bear them. To establish young plants, the fronds may be pegged on some cocoa-nut fibre refuse, into which they will soon root. I find this variety varies considerably when raised from spores.

The *Woodwardias* afford further examples. In *W. radicans* one rather large bilbil is formed on the midrib towards the end of the frond, and in *W. orientalis* the whole upper surface of matured fronds is covered with tiny bulbils, each of which has one small frondlet standing erect. This gives the plants a very attractive appearance, especially where they are well exposed to the light, as they then have a rosy pink shade. The slightest touch will remove them, and if treated carefully, hundreds of plants may be obtained from one frond.

Among *Adiantums* we have some remarkable examples, as *A. ciliatum*, better known perhaps as *A. Edgworthi*. In a humid atmosphere the young plants at the extremities of the fronds will continue to grow until they in their turn form others, thus giving three or sometimes four generations all attached. The nearly allied species *caudatum* is somewhat similar, but I have never seen this bear more than one young plant at the extremity of each frond. *A. dolabriforme* is another interesting example, and quite as prolific as *A. ciliatum*, while *A. lunulatum*, the deciduous species, should be included. This has larger fronds, but through losing its fronds in winter is often lost altogether. These may be treated the same as the *Gymnogramma* referred to above. *Aspidium cicutarium* is a remarkably distinct example; the round bulbils, which are very abundant, drop off, and wherever they find genial conditions they soon make plants. There is little difficulty in propagating *Hemionitis palmata*, as young ones are produced on the basal fronds and take root in the same pot. *H. cordata* is also easily managed, and may also be readily obtained from spores. *Goniopteris prolifera* is another example, producing two or three bulbils towards the extremities of the fronds, and these will attain to a fair size on the parent fronds. In all instances where the fronds are not on the surface where the bulbils can take root, it is advisable to remove them from the fronds as early as possible, as this will save the first young roots which appear as soon as the second fronds start. In all cases care should be taken

that bulbils or young plants do not suffer through being allowed to get dry after they are taken off. Damping is much more likely to set in when the tiny fronds get withered. A close atmosphere and shading are necessary, but air should be given early in the morning for a short time to sweeten the atmosphere. This is often neglected both in the Fern and other propagating houses, and I know nothing so important as avoiding a stagnant atmosphere.

A. HEMSLEY.

## TREES AND SHRUBS.

### DEUTZIA LEMOINEI.

*DEUTZIA LEMOINEI*, which first made its appearance at a meeting of the Société Nationale d'Horticulture de France, April 12, 1894, and the

*Deutzia Lemoinei.* Engraved for THE GARDEN from a photograph sent by Mons. Y. Lemoine, Nancy.

exhibition of which was the subject of a laudatory notice in the Bulletin of that society, is a hybrid between *D. gracilis* and *D. parviflora*. On the occasion referred to the society pronounced this new variety worthy of its highest awards, viz., a first-class prize and a first-class certificate of merit.

*DEUTZIA GRACILIS* (Zucc.), which grows in moist valleys in the mountainous regions of Japan, is a small tufty shrub with lanceolate leaves and white flowers, produced in separate or detached clusters, and having glabrous anthers borne on the middle point of three-lobed filaments. This species, which was introduced by Siebold about the middle of the present century and put into commerce by M. J. Baumann, nurseryman, of Ghent, is now grown almost everywhere. It is raised in large quantities for forcing, and we are informed in the *Nouveau Jardinier* that "it is the finest of all shrubs for that purpose." It is hardy, and delights in a light, cool, moist soil, of which heath soil forms a large proportion.

*DEUTZIA PARVIFLORA* (Bunge) is a recently-introduced shrub, a native of the northern parts

of China and the region of the river Amoor, whence it was introduced into the Imperial Botanic Garden at St. Petersburg, and was afterwards sent to the Arnold Arboretum at Cambridge, in the United States of America. Professor Sargent, the learned director of the last-named establishment, sent us a few branches of it, one of which produced a shoot which took root and grew, and thus it came to pass that I was the first in Europe to put this fine species into commerce. About the same time two or three plants of it, raised from seed sent by Professor Sargent in 1887, came into bloom in the gardens of the Muséum, at Paris. This plant forms an erect tuft, seldom exceeding 5 feet in height, with rather stout rigid stems, vertical in growth, and elliptical or lanceolate leaves of a deep green colour, toothed, and strongly veined and wrinkled on both sides. The stems of the previous year's growth bear throughout their entire length small corymbs of flowers, which are exactly similar in form to those of the Hawthorn. The flowers are fully opened out, and the petals, which are creamy-white and roundish in shape, are contracted at the base into a very narrow claw, thus exposing the calyx to view, as occurs in the flowers of many rosaceous plants. The stamens are of a light yellow colour, and the filaments are simply widened at the base, but not auricled at the apex. This is the earliest flowering species of the whole genus, as it comes into bloom in April some days earlier than *D. gracilis*. It is also well adapted for forcing, and is perfectly hardy in the climate of Nancy, where the varieties of *D. crenata* are often cut down to the ground by frost. Fertilised with pollen of *D. gracilis* in the spring of 1891, seed of *D. parviflora* produced a number of hybrid plants which, planted out in the open ground in the second year of their growth, have borne uninjured the frosts of the last three winters. These plants form tufts averaging about 32 inches in height, the branches of which, all erect, are furnished in the early days of May with panicles of flowers, and at that time one may count on each plant from 1000 to 1500 flowers or flower-buds. In its general appearance

*DEUTZIA LEMOINEI* is intermediate between its two parents, of which it only inherits the qualities. Its branches are straighter, firmer, and more solid than those of the male parent (*D. gracilis*), and more regular in appearance, shorter, and more numerous than those of the female parent (*D. parviflora*). The flower-clusters, growing from all the axils on the branches, make their appearance at an early date, and are produced with such regularity that no vacant spaces can be observed, while it is not unusual to see parts of the long stems of *D. parviflora* here and there devoid of flowers in a random sort of way. The inflorescence of *Deutzia Lemoinei* resembles neither the corymb of *D. parviflora* nor the elongated cluster of *D. gracilis*, but takes the form of an erect branching panicle, which is sometimes hemispherical in shape and sometimes like a broad-based cone. Each panicle bears from fifteen to twenty-five large, well-opened flowers, which are each about an inch in diameter, and present an appearance quite novel amongst the *Deutzias*. The petals are broad, oval, undulated at the margin, of a pure white colour, and entirely cover and conceal the lobes of the calyx. The stamens are of a reddish-yellow colour and the filaments are three-lobed. The flowers of *Deutzia Lemoinei* are fully opened out, while the pointed-petalled flowers of *D. gracilis* are generally not well opened out. The flowers of *D. Lemoinei* also stand so closely together as to completely hide the peduncles and pedicels from view, differing in this respect from the flowers of both *D. parviflora* and *D. gracilis*. *Deutzia Lemoinei* is a first-class shrub for forcing, as was evident from the few specimens exhibited in April, 1894, at the meeting of the Société d'Horticulture de France. These specimens had been taken up and potted in the autumn preceding and then grown on in a cool house. Had they been placed in a temperate house, they would have come into flower much earlier. The plants grown in the manner de-

scribed are well shaped, regular in form, laden with pure white flowers, and not encumbered with superfluous foliage. Grown side by side with plants of *D. gracilis* they quite eclipse the latter by their beauty, so that I think I am warranted in venturing to predict that this new variety will ere long be largely grown for forcing, and that it will eventually supersede *D. gracilis* for this purpose. When grown in the open air *D. Lemomei* requires no special attention, and consequently may be successfully cultivated in any garden, even the smallest. Quite as free-flowering as *D. gracilis*, it surpasses the latter in hardiness and vigour, grows much faster, and thrives in any kind of soil. EMILE LEMOINE.

**Hibiscus syriacus Jeanne d'Arc.**—Despite the great number of varieties of this autumn-flowering shrub that we have in our gardens, the only white variety that I have known for any length of time is *H. totus albus*, whose blossoms, though pure white, are single. There is a double form known as *H. albus-plenus*, but though the major portion of the petals is white, yet they are marked with red at the base, and in this way they form a reddish centre to the flower. *Jeanne d'Arc* is quite a pure white double flower, and forms a pleasing variety to those already in cultivation. The new-comer is, like nearly all the others, of Continental origin, and is said to be a pure white sport from the parti-coloured variety *Duchesse de Brabant*, a very pretty kind.—T.

**Ampelopsis muralis.**—This form of *Ampelopsis* does not seem to be generally known, yet it has appeared in some of the Continental catalogues for years. It is not to be found in the Kew hand list, in which a considerable number of Vines and *Ampelopsis* is given. The *Ampelopsis* in question is apparently a variety of the Virginian Creeper (*A. hederacea* or *quinquefolia*), but it differs in a marked manner from the ordinary form, as it will cling to a wall or any other support almost as tenaciously as the ever-popular *A. Veitchi*, while it grows as freely as the common Virginian Creeper. Hence it is especially valuable where it is desired to quickly clothe a wall with foliage, as no nailing or securing is required, but the shoots attach themselves by the flattened points of their tendrils exactly as in *A. Veitchi*. The foliage as a rule dies off brightly coloured, but this year, despite the fine weather we have had, the colouring of the Virginian Creeper does not appear to be so uniformly bright as it generally is.—T.

**Sambucus racemosa.**—If this, the Scarlet-berried Elder, could be induced to fruit as freely as the common kind, it would doubtless be planted much more frequently than it is, for to many people it is quite unknown, though when laden with fruit it is very ornamental. From a foliage point of view, too, it deserves recognition, not so much the typical kind as some of the cut-leaved forms. Loudon mentions one cut-leaved variety, *laciniata*, but there are now some three or four differing more or less from each other. The variety most generally met with is *serratifolia*, which forms a very graceful specimen. In the spring of the present year a charming form was awarded a first-class certificate by the Royal Horticultural Society under the name of *Sambucus racemosa plumosa aurea*. The leaves of this are of a very pleasing shade of pale yellow, and no doubt by exposure to the full rays of the sun they would acquire a rich golden hue, as in the case of its relative, the golden form of the common Elder.—T.

**Ampelopsis Veitchi.**—There is evidently considerable deviation from the type in the forms of this handsome creeper. In my own garden three variations occur, which, as two of the plants occupy between them a side of the house and the third covers an adjoining wall, can be readily compared during growth. They were all procured from the same nursery and were planted at one time. No. 1 is the form that we are accustomed to consider the type—close-growing, with moderately small and smooth leaves. No. 2 has leaves that are slightly larger, stand out further

from the wall, and which have surfaces more or less rough and corrugated. This variety is a slower grower than the other two, and its leafage turns colour and falls a full week earlier. The third is the most striking in effect, producing very large leaves, one of which I have just picked for the purpose of measurement. I find that the extreme breadth is  $12\frac{1}{2}$  inches, the length, from the setting on of the stalk to the point,  $7\frac{1}{2}$  inches, and the stalk itself  $10\frac{1}{2}$  inches. I have never previously measured a leaf of *A. Veitchi*, but do not remember to have seen a larger.—S. W. F., *Torquay*.

**Eucalyptus citriodora.**—"T.'s" note on this induces me to give my experience with it. Of over twenty species of the Gum trees which I have grown this is the most difficult to keep. Several times I have raised it, but it never survives the third winter, and another grower, a professional in this neighbourhood, finds the same difficulty with it. I rather think it needs a warmer winter temperature than the others, and at the same time plenty of fresh air. I do not know its native country; it may be from the warmer parts of Australia.—J. M., *Charmouth, Dorset*.

**Wistaria sinensis.**—An old specimen of this climber, which covers a wall of about 20 yards in length and the circumference of whose stem is over 1 foot 8 inches, has this year made vigorous growth, having sent out several long suckers, the longest measuring over 30 feet. The ends of three of the shoots are fasciated, one being  $1\frac{1}{2}$  inches in breadth at its extremity. For a long time this *Wistaria* made scarcely any growth, but it has flowered abundantly every year.—S. W. F., *Torquay*.

**A large Magnolia tree.**—A fine specimen of *Magnolia grandiflora* (the Exmouth variety) is growing here in a sheltered valley. The tree is a standard, and is situated in a gravelled yard with buildings on two sides of it. Its present measurements are as follow: Circumference of trunk at ground, 4 feet 7 inches; widest spread of branches, measured in a straight line, 34 feet 6 inches; measurement of spread at right angles to fore-going line, 26 feet; height, 20 feet. This height was exceeded by about 10 feet previous to the blizzard of March 9, 1891, when the upper branches were broken off. Two subsidiary stems, presumably suckers, about 18 inches in circumference, rise on each side of the main trunk. The tree is in the best of health and is making good growth, so much so that the damage done by the blizzard is not now apparent. The severe weather of last winter caused many of its leaves, as well as all of the buds then formed, to drop when the sap commenced to move in the spring, but otherwise the tree is uninjured, and is now bearing a late and rather scanty crop of flowers. During last year it bloomed profusely, bearing considerably over 300 blossoms, the first opening in June, while the last was cut and brought into the house in November. The greatest number of flowers open at one time was twenty-nine. The branches on one side of the tree come to within a foot of the ground. I find it impossible to discover the age of this tree, but I am told by a resident seventy years of age that it was a big tree when he was a little boy.—S. W. F., *Torquay*.

**The bird nuisance.**—I never remember the birds being more troublesome and destructive than they have been this season. Fully two-thirds of our Pears, where unprotected with nets, have been destroyed by them. The tomtits seem to be the worst aggressors, and I shall be very grateful for any hint as to the best means for destroying those little pests. No doubt some will tell me I shall be destroying my best friends. I know of nothing more exasperating than to see so many of the best fruits destroyed. I would not grudge the birds a fair share if they would only finish what they begin before attacking others, but they slightly peck the stem end just enough to set the fruit rotting, and are off to another. Apples, too, have been badly attacked by the tits,

the finest Blenheims or Peasgood's Nonsuch having a great attraction for them. These tits are far more destructive than bullfinches; I have never known the latter to attack fruit.—W. M. SANGWIN, *Trelissick, Truro*.

## CHRYSANTHEMUMS.

### OVER-STAKED CHRYSANTHEMUMS.

PRIVATE gardeners as a rule use far too many stakes for their bush Chrysanthemums. In some instances little else but sticks are to be seen till near the time of flowering, and even when the earlier growths are strong and branching yet much more staking is done than is absolutely necessary. When it is the grower's aim to produce large, globular-shaped, yet not exactly formally trained or exhibition plants, the summer stopping is frequent and the mass of shoots resulting is spindly, not being equal to producing more than weak terminal heads of flowers, disbudbing not greatly improving matters. Such growths may require to each have a stake, but since the days when I spent hour after hour perched on a flower-pot staking Chrysanthemums, my aim has been to break away from the unnatural method of growing and training these serviceable late autumn and winter-flowering plants. That they can be made to produce far more flowers with the aid of a very few stakes I have repeatedly proved, and this season I have been more than ordinarily successful in this direction. Private growers will do well to "take a leaf" out of a market grower's book, or, in other words, to adopt his practices as far as growing decorative Chrysanthemum plants is concerned. It will be found that the more naturally grown the plants are and the fewer stakes there are used about them the more flowers there will be on the plants and the more effectively the plants can be grouped. Nor are these the only advantages. Now-a-days abundance of cut bloom is wanted in most establishments. From the un-staked or only lightly staked plants it is possible to cut quantities of flowers, and yet not greatly disfigure them, but if we cut a few heads of bloom from the much-staked plants, they are practically spoilt for conservatory decoration. Compare the much-stopped, closely-staked plants with those grown in the open borders and you then have an object-lesson, the value of which there ought to be no mistaking. The border plants have been allowed to grow, branch and flower naturally, and, should the present favourable weather continue a few days longer, there will soon be a grand display in the open air.

Those of my readers who have started plants with a view to growing a few blooms for exhibition, and then allowed some of these clear-stemmed plants to branch and flower naturally will probably admit that they have been agreeably surprised at the results. Such great branching heads are effective in large conservatories and afford a profitable supply of cut blooms, but they are not what market growers prefer and not always the best for private places. That, however, is no excuse for going to the other extreme, pinching and stopping unduly with a view to having the plants extra dwarf. Instead of stopping the cuttings in the cutting pots, pans, or boxes, wait till they have been in  $2\frac{1}{2}$ -inch pots long enough to become established and then lightly stop them. In this way four or more shoots will be had, and it is these that should lay the foundation of the future plants, and very different to those resulting from a quantity of soft sucker growths ob-

tained by much closer stopping. In looking through my stock of plants I find no failures under this method of treatment; in fact, more free-flowering Chrysanthemums could not well be had. W. H. Lincoln, which is perhaps the most profitable low variety in cultivation, succeeds particularly well when not frequently stopped. My plants were lightly stopped when about 6 inches high, and from each three or four strong breaks resulted. These were stopped when from 10 in. to 12 in. long and afterwards allowed to break naturally. On an average there are a dozen growths springing from each of these main branches, and the precaution having been taken to remove early formed buds, I shall have abundance of fine single blooms (all are disbudded) during December, with stems that may be cut to a length of 12 inches to 15 inches. Three, or at the most four, light Bamboo stakes are placed to each plant, and these are ample for the purpose of preventing breakdowns. This variety is given 10-inch pots. Edwin Molyneux is another popular and serviceable variety, and I grow it extensively. In this instance the cuttings were nearer 9 inches in length when stopped, and the three or four resulting stem-growth broke naturally, a crown-bud forming at the point of each when about 2 feet long. There was no necessity to remove these buds, and the plants are now furnished with from twenty-four to thirty growths, each 15 inches long and surmounted by a good bud. This variety succeeds best in 9-inch pots and requires four stakes to keep the growths up together. Particularly useful plants can be had of Fair Maid of Guernsey, which, if allowed to divide and sub-divide naturally, may be had at their best late in December. Mine are in 10-inch and 11-inch pots, and range from 4 feet to 5 feet in height, yet three or four stakes are sufficient to support four dozen flower stems. Florence Piercy is even more free-flowering if allowed to branch naturally. Treated similarly to Fair Maid the plants are 4 feet high and will carry not less than three dozen disbudded blooms. In Mlle. Lacroix we have another free-branching variety that requires little or no staking, always provided frequent stopping is not resorted to. L. Canning, the market grower's favourite mid-winter variety, though by no means of a robust habit of growth, yet requires only three or four stakes and two strips of raffia to keep the growths from sprawling about. Plants in 10-inch pots are not more than 2 feet high, and will give two dozen good late blooms. I had nearly forgotten my old favourite Lady Selborne, yet this is one of the very best for growing in the more natural manner. Cuttings should be struck early in the winter, stopped when 6 inches high, and again when the shoots following are 6 inches long, afterwards allowing them to extend and branch naturally, disbudding freely, in order to have medium-sized blooms with stems not less than 12 inches long. My plants in 10-inch pots are 5 feet high and furnished with from three dozen to four dozen blooms, with abundance of spray to follow from the hard lower portion of flowering growths.

Many of the newer varieties promise to succeed well under this method of culture. Florence Davis in 9-inch pots and only lightly stopped is well furnished with long, if somewhat spindly, flowering growths, yet three stakes are sufficient to support the lot. Beauty of Exmouth is somewhat stouter and scarcely so free-flowering. In this instance some of the plants were stopped when 12 inches high, and not again afterwards. Thomas Hewitt, Viviani

Morel, Bruce Findlay, T. Wilkins, a beautiful yellow variety, Duke of York, and a few others have been similarly treated with excellent results, each carrying from a dozen to fifteen strong buds with long stems. Princess Victoria, a very promising late variety if only lightly stopped, forms a few long, soft, yet very free-flowering growths. If not disbudded, each growth would be furnished with a terminal head and side flowers to a length of 12 inches. J. S. Dibbins is sturdier and requires few or no stakes. W. IGGULDEN.

**Chrysanthemums from Japan.**—Messrs. Cannell and Sons, of Swanley, have this autumn started somewhat of an innovation by distributing under the native names some new Chrysanthemums they have imported from Japan. They are Kumo-no-ue, or White Good Gracious, Usugesho, a Japanese incurred lilac-pink, with reverse of silvery pink; and Shink-a-garibi, of a golden bronze and terra-cotta colour. Messrs. Cannell's new departure may well be recommended to all importers of this popular favourite, but especially those on the other side of the Atlantic. By far too much confusion has been caused on account of these native names being suppressed and English or American ones bestowed in their place.—CHRYSANTH.

**A French Chrysanthemum committee.**—The editor of the *Revue Horticole*, of Paris, in a recent issue devotes some space to the support of Mr. H. Fatzer's suggestion that the National Horticultural Society of France should form a committee to look after the interests of the Chrysanthemum, which is essentially a French flower. After quoting an article in an English contemporary, the *Revue* mentions the existence of the N.C.S. here, the American Chrysanthemum Society and the Société Nationale des Chrysanthémophiles of Brussels, and adds that it is difficult to understand why France—which has given rise to most of the varieties cultivated at the present time, and which takes so keen an interest in the flower—should remain in the rear of other nations in this respect. An outline of the lines upon which the proposed committee should work is then given, which will certainly meet with the approval of Chrysanthemum growers here. Let us hope that early in the season a meeting of the leading French Chrysanthemum specialists will be held to discuss the proposal.—C. H. P.

**October Chrysanthemums.**—These seem to be becoming more numerous every year, and as they are chiefly of the large-flowering section, it was an excellent idea of the N.C.S. to hold an October show, by which means many varieties are brought before the public notice which would otherwise perhaps be too late for the ordinary shows in November. I notice the next meeting of the floral committee will be on the 8th prox., the corresponding meeting last year being on the 10th. On that occasion eighteen new varieties of merit were staged, the principal being Frank Wells, Souvenir de Petite Amie, President Armand, Th. Denis, Exmouth Yellow, Petit Délaux, Préfet Robert, Mrs. E. G. Hill, Mme. C. Molin, Commandant Blusset, Mrs. W. H. Lees and Duchess of York. Some of these were certificated, and it will be interesting to see, on the occasion of the next Aquarium show, whether they maintain their reputations and justify the awards that the committee made last year. Among other varieties shown in good form last year at this meeting were Mlle. Thérèse Rey, President Borel, Mrs. C. Harman-Payne, Eda Prass, Louise, W. Tricker, Mme. E. Rey, William Sward, Comte de Germiny, W. H. Lincoln and Van den Heede.—CHRYSANTH.

**Pompon Chrysanthemums.**—Nothing but large flowers seem to be appreciated by the public at the present time; hence when a prize is offered at any of the exhibitions for pompon Chrysanthemums it is in nearly every case bestowed upon those flowers in the cultivation of which disbudding has been carried out most rigidly; in fact to

such an extent, that in many cases they bear no resemblance to the pompon varieties of old, consisting, as the exhibit does, of three blooms of one variety, each flower being expanded to the utmost extent and not a trace of a bud to be seen. There is to my mind an immeasurably greater amount of pleasure in seeing a few clusters of flowers, some fully and others only partially expanded, with their attendant buds than there is in very formal flowers each supported on a piece of clear stem.—T.

#### NEW EARLY CHRYSANTHEMUMS OF 1895.

For some few years past the admirers of early Chrysanthemums have indulged in the hope that a rapid advance, almost perhaps corresponding to that which has taken place in the later section, was at hand. Their improvement and extension seem, however, to have been somewhat limited when the large number of new varieties that have been recently sent out is taken into account, as the display of early Chrysanthemums at the September shows at the Aquarium hardly justifies the hopes that have been entertained. With a few exceptions here and there, very few of the novelties are staged at those shows, most of the exhibitors apparently preferring to rely upon old-established sorts such as the Desgrange family, Comtesse Foucher de Careil, Lady Fitzwygram, and a few others in the large-flowering group, together with an abundance of the early pompons that have been much longer in cultivation.

At the recent show a few novelties were seen, the best of them being Mme. Carmiaux, a white flowered kind; Notaire Groz, a mauve-coloured variety, with a tinge of rose; and Harvest Home, yellow and orange-bronze. It may be that those who admire early varieties the most do not belong to the class of exhibitors, but prefer to keep the new acquisitions at home in the open border to adorn their gardens; but it seems most probable that if new early ones as a class were really of any great value, some members of the trade would take this opportunity of making their merits known. When we consider the intensity of colour to be found in Dahlias, Gladioli, Asters, Zinnias, &c., we cannot fail to be struck with the fact that early Chrysanthemums, excepting the whites and yellows, are wanting in purity of tones which would make them of value. The bronzes, mauves and reds are, in the light of a fine September day, dull and unattractive, and it must ever be the aim of raisers of this race to impart to their favourites something of the brilliancy of colour which characterises the later race. When this is achieved and greater size than is found in most of the new kinds is obtained, public estimation will no doubt be bestowed upon early Chrysanthemums to a greater extent than at present.

As show flowers they cannot be said to hold a very high place. Useful in groups and in funeral wreaths, the white varieties will long be sought after by florists, but the somewhat magniloquent descriptions of the raisers have led us to expect much more than this. We have been told that the new early ones of the past few years are to compete in all respects with the popular November race, a promise that as yet is a long way from realisation.

The following is a list of the novelties announced for the present year. They are all in the hands of the English trade, and we may well hope to see them next autumn in something like presentable form:—

*Alfred Droc* (Délaux).—Japanese; golden yellow, covered with red, fine petals.

*Ambroise Thomas* (Délaux).—Japanese; long petals, crimson-red, lightened gold, tipped bright gold, golden centre, dwarf.

*Bouquet de Feu* (Crozy).—Fiery brick-red, dwarf and free.

*Chanteur Ninon* (Crozy).—Purple-red, reverse bronze.

*Colibri* (Crozy).—Purple-chestnut-red, reverse copper ochre, dwarf.

*De la Guille* (Crozy).—Long petals, dark chrome-yellow.

*Eclairer* (Bouchelat).—Bright purple and lilac at base, broad petals.

*Emily Grunerwald* (Délaux).—Canary yellow, centre and tips violet-red.

*Erectum Album* (Crozy).—Broad flat petals, snow-white.

*Etienne Devillat* (Crozy).—Coppery red, reverse dark buff.

*François Vuillemet* (Délaux).—Japanese; broad petals, rosy violet, silvery centre.

*Gladiateur* (Boucharlat).—Japanese; broad petals, rose-violet, reverse silver.

*Grunerwald* (Crozy).—Purple-red; colour and form of Cullingfordi.

*Jean Vuillemet* (Délaux).—Japanese; dark brown-erimson, centre and reverse old gold.

*Jeanne Thérèse* (Délaux).—Incurved Japanese; broad petals, silvery white, shaded rose, centre golden.

*Luteum* (Boucharlat).—Japanese; canary yellow.

*Mme. Albert Menier* (Délaux).—Japanese; broad white petals, centre dark cream.

*Mme. Armand Groz* (Délaux).—Japanese; fine petals, rose nankeen, shaded white, centre red and old gold.

*Mme. Biessy* (Crozy).—White, passing to soft rose.

*Mme. Charreton* (Crozy).—Long petals, soft satin rose.

*Mme. Casimir Perier* (Délaux).—Japanese; milk-white, shaded cream, centre yellow, surrounded with dark violet-rose.

*Mme. Delcante* (Délaux).—Japanese; bright yellow, drooping petals.

*Mme. Emile Nonin* (Délaux).—Long drooping petals, milky white, centre darker.

*Mme. Gajac* (Délaux).—Broad petals, violet-rose, glazed silver.

*Mme. Léon Carnet* (Délaux).—Japanese; broad petals, white, shaded rose, centre greenish yellow, dwarf.

*Mme. Schapler* (Crozy).—Long drooping petals, straw-yellow, centre canary.

*Marie Cavalier-Cointet* (Crozy).—Broad goffered petals, white, passing to rose.

*Massifaire* (Crozy).—Light mauve-rose.

*Michel Coulouvat* (Crozy).—Broad petals, purple-red.

*Mignonne* (Boucharlat).—White ground, edged bright purple, broad petals.

*M. Buckmann* (Délaux).—Long drooping petals, salmon-red, lightened gold, centre golden yellow, reverse silvery.

*M. Coulin* (Délaux).—Long petals, bright old gold, edged and shaded coppery red.

*M. Disland* (Délaux).—Broad incurved petals, canary-yellow, shaded coppery red.

*M. Georges Menier* (Délaux).—Japanese; long petals, violet-amaranth, reverse silvery.

*M. Lévêque fils* (Délaux).—Bright golden yellow, tipped dark crimson-red.

*M. Lévêque père* (Délaux).—Broad petals, red, lightened salmon, dwarf.

*M. Regnault de Molmain* (Délaux).—Japanese; broad drooping petals, colour creamy white, shaded rose, centre darker.

*Notaire Groz* (Délaux).—Long drooping petals, mauve-rose on a silvery white ground, delicate colour.

*P. Crozy* (Crozy).—Broad petals, slightly incurved, purple-red.

*Pépiniériste Léon Carnet* (Délaux).—Rose, shaded white, centre golden yellow, passing to cream, broad petals, dwarf.

*Perle des Massifs* (Crozy).—Moss-rose, very free.

*Préjet Cassagneau* (Délaux).—Long drooping petals, fiery crimson.

*Président Michelli* (Crozy).—Long petals, yellow, shaded carmine-red, reverse ochre.

*Sirène* (Boucharlat).—Broad petals, rosy pink.

*Souvenir de Charlotte Baillet* (Délaux).—Japanese; cream, shaded violet-rose.

*Souvenir de M. Auguste Nonin* (Délaux).—Japanese; golden red, tipped yellow.

*Surpasse Gustave Grunerwald* (Délaux).—Broad petals, silvery white, flamed violet-rose.

*Triomphe de Lyon* (Boucharlat).—Incurved; broad petals, dark rose, shaded purple, tipped gold, passing to canary, reverse sulphur-rose.

C. HARMAN-PAYNE.

**Chrysanthemum Colonel Chase.**—Unlike very many of the newer varieties of Chrysanthemums which are sent out with a great flourish of trumpets, the variety under notice is a notable exception. It is a refined and magnificent flower without the least sign of coarseness. In colour it is a kind of creamy blush with a pinkish shade over the whole, the petals drooping gracefully. It is also a good grower, my plants ranging about 5

feet in height and carrying their foliage well.—A. YOUNG.

**Chrysanthemum Ryecroft Glory** is well maintaining its reputation as the best of out-of-door yellow-flowered Chrysanthemums. With me it grows 4 feet high on a west border. The colour, golden yellow, is much appreciated at this time of year, as it contrasts so well with the various autumn-tinted foliage so much in use for filling vases.—E. M.

— This is a brilliant and attractive variety, and most useful for cutting or conservatory decoration. Its value is enhanced from the fact that it comes into flower after the autumn varieties, such as Mme. Desgrange and Miss Cullingford, and before the ordinary November sorts open, this being a rather scarce time for flowers generally. In seasons like the present it is a good plan to place Ryecroft Glory behind a north wall, that is if the flowers are not wanted till the first or second week in November. This is an important time with me, and I should be glad if some reader would name a good free-flowering graceful white Japanese variety to come in with Ryecroft Glory. I used to grow James Salter, which produced enormous quantities of bloom early in November, but my employers objected to the colour, so I discarded it. I may mention that I do not disbud to any extent, small flowers and plenty of them being preferred to large blooms.—J. C.

**Chrysanthemums damping.**—I enclose some flowers and leaves from my Chrysanthemums, and would be obliged if you would let me know through THE GARDEN what you think is the cause of their damping. They are in a good airy house free from drip, and a little fire-heat is turned on in damp weather. The leaves look as if they were attacked by some fungoid growth; probably it may be the disease that Golden Wedding was attacked with last year, only in an aggravated form. The plants have not to my knowledge had an excess of liquid manure.—W. J. M.

\* \* Your Chrysanthemum plants are not attacked with the fungoid disease so general last year in the case of Golden Wedding, nor can the present condition of your greenhouse cause them to do so badly. Too much liquid manure is certainly the cause of similar decay seen in more than one instance lately. The soil becomes soddened and sour by over-strong doses of stimulants, which the leaves cannot assimilate. Clogging the soil by watering too frequently towards the end of the growing season, when the leaves have ripened, will also lead to such decay as is seen in the specimens sent. It is advisable to sweeten the earth and roots by allowing the same to become dry, almost to the point of causing the foliage to flag, subsequently applying moisture only when you are certain, by careful examination of the soil, that the roots require it.—Ed.

#### SHORT NOTES.—CHRYSANTHEMUMS.

**Chrysanthemum Noces d'Or** belongs to the Japanese incurved section. The petals are narrow, forming a full solid bloom when fully expanded. The colour is a rich golden yellow on the upper surface, the reverse paler. E.

— This is a Japanese incurved, with grooved florets of medium width. The blooms are of good size and very full, and the colour is a rich golden yellow. It was raised by Ernest Calvat and sent out in the spring of last year. It is somewhat early, and has already been shown this season in very good form.

**Chrysanthemum Emily Spilsbury** is stated to be a cross between Condor and Miss Anna Hartshorn, the former a French and the latter an American variety. The blooms are large, the florets long, grooved, and slightly intermingled. The blooms are rather spreading than globular, and the colour is a distinct shade of dead white.

**Chrysanthemum President Armand.**—A novelty sent out last year, and, like many from the same source, a Japanese incurved. It is capable of great development, and when well grown is a big, massive-looking show flower. The florets are of great length, curling inwards and pointed at the tips; they are also deeply grooved. The inside colour is carmine-

chestnut and the reverse a distinct shade of brassy yellow.

**Chrysanthemum A. H. Fewkes** is another American incurved Japanese, but of a less massive type than Philadelphia. The blooms are not so globular and the florets are much narrower and pointed at the tips. The colour is a very pure shade of deep golden yellow. It comes early into flower, and has been commended by the floral committee of the N.C.S.

**Chrysanthemum Boule d'Or.**—One of Ernest Calvat's best productions and quite new this autumn, although the name is an unfortunate selection on account of another well-known exhibition flower being so called. The florets are very broad and deeply grooved, somewhat pointed at the tips, and forming a remarkably massive bloom. Those who know Louise will appreciate its merits when I describe Boule d'Or as a golden amber counterpart of Louise.—C. P.

**New white Japanese Chrysanthemums.**—Although somewhat early in the season, there have been several good additions to this class. Lady Esther Smith, raised by Mr. R. Owen, has already been described in these columns. Mme. Ad. Chatin is of the Japanese incurved type, good and solid, colour very pure. M. Montigny is a Japanese, with long toothed florets. Miss Alice Lowe has long curly florets of medium width, and Mrs. R. Jones, quite new, has very long tubular florets, and is a big flower. Mutual Friend is of American origin. Several very first-class white Chrysanthemums were seen last season from the same source, notably Niveam, The Queen, and W. G. Newitt.

**September and October Chrysanthemums.**—Large numbers of these are of French origin, quite confirming the opinion expressed last season that the American varieties are later in coming into flower in this country than the French. Most of the new flowers that were open by the first week in October were seedlings of M. Ernest Calvat, although Messrs. Lacroix and Délaux were represented to a small extent. Some good blooms, however, of American varieties were staged at the October show, such as Eda Prass, Mrs. E. G. Hill, Wm. Tricker, Julius Roehrs, W. G. Newitt, and one or two more.—CHRYSANTH.

## GARDEN FLORA.

### PLATE 1037.

#### NYMPHÆA MARLIACEA IGNEA.

(WITH A COLOURED PLATE.\*)

THE story of the beautiful Water Lilies raised by M. Latour-Marliac has been told so fully and recently in THE GARDEN, that there is no need to go over the ground again, but other kinds have been raised, and the past year has been one of great beauty among Water Lilies. In my own Lily pond they were very beautiful for nearly five months, and people who have under other conditions all the kinds that I have were surprised to find how much better some of them did in the open water than in fountain basins and tanks. Whether owing to the greater mass of mud at the bottom of the pond or to perfect freedom to ramble where they liked, or to some other cause, I do not know, but they were a sight to see. Among them bloomed the beautiful Water Lily which is here figured—not a very large kind, but of rich and lovely colour, which can be but feebly shown in colour-printing. The plant was not strong enough to give us many blooms, but when stronger it will be very effective. The effect of the red Water Lilies is quite distinct from that of the large white, primrose and flesh-coloured kinds; they seem to come from a different species, flower freely,

\* Drawn for THE GARDEN by H. G. Moon in the open water at Gravetye Manor, Sussex. Lithographed and printed by Guillaume Severeyns.

蓮花與蓮蓬

and have a distinct growth. The effect of the colour is better the closer they are looked into. They are effective at long distances. N. Robinsoni flowered also, but it was thought best to let the plant get stronger before making a drawing of the flower. W. R.

**Clematises** are conspicuous now in several northern gardens, and some of the best and freshest autumn colour is furnished by them. This is in part the result of last winter, which cut the plants down to the ground and a vigorous growth with later blooming has been the result. This suggests a way of further and annually prolonging their flowering season. The terrace wall of Chillingham flower garden has several extra bright spots where Clematises are blooming, and at Eslington also in addition to C. Jackmani we noted C. lanuginosa nivea, with its delicate pale lavender flowers, also the snow-white Jackmani, which, like the other so-called white variety, is not of the Jackmani type at all, but in colour is true to its name, a lovely starry flower of spotless purity.

## THE WEEK'S WORK.

### KITCHEN GARDEN.

**WINTER CUCUMBERS.**—Plants in pits and frames are now on the move—in fact, where the bottom and top heat had to be kept up by fermenting material alone, no more fruit can be expected, as not only are the nights, but the days also too cold. This being so, a few fruits must be allowed to swell off on the earliest planted lot of winter fruiteders. No more, however, than are absolutely necessary for present wants must be allowed to remain on the plants, as what the cultivator must study is the retention of all the vital force possible, as such will be wanted during the several dark, sunless months which lie before us. I have previously urged the necessity of employing as little fire-heat as possible, and as long as fair weather and moderately warm nights continue, this rule must be adhered to, as short-jointed laterals and stout, robust foliage are about the best guarantee for the plants passing through the winter free from attacks of their greatest enemy, red spider and thrips. October being past, great care must be exercised in the use of the syringe or wet foliage, through hours of darkness especially, should the thermometer fall below the minimum figure, would soon produce a yellowness and dropping of the fruit, a condition from which the plants are not easily brought at this period of the year. The best and indeed only safe way is to watch for extra fine sunny days, and then to close the house, say at 1 p.m., giving the foliage a somewhat vigorous bath with tepid soft water, and when dull and sunless to be content with atmospheric moisture. Where evaporating pans are fixed to the hot-water pipes, they should be filled with diluted farmyard liquid, the steam from this helping to ward off insects as well as promoting a healthy growth. Avoid crowding the growths, and train the shoots regularly and frequently to the trellis, pinching out the points of the leaders as they reach their limit. Surface-dress each time fresh roots appear on the top of the mounds, but beware of adding much at a time, as this only becomes sour. Half an inch of sweet fresh loam to which have been added some quite new horse manure and a little powdered mortar or plaster rubble suits them well. Let watering be done by no half measures, but allow the roots to need it, and then soak the bed from summit to base with diluted liquid at a temperature of 90°. Air cautiously, a very little serving to sweeten the atmosphere and prevent scorching, and if on sunny afternoons by reason of early closing the glass touches 80° so much the better. As a portion of this solar heat remains in the house a good part of the night, the need for fire-heat is greatly lessened. Should thrips put in an appearance

fumigate mildly two nights in succession, this being safer and more effectual than one heavy dose of tobacco fumes.

**FIELD POTATOES.**—In large establishments Potatoes for the winter supply are usually grown in a field on the home farm. All varieties, even the very latest, being now ready for lifting, such should be done without further delay, as repeated rains encourage disease; moreover, many of the tubers may be destroyed by frost early in November should such occur immediately after a heavy rain. Some separate the seed portion of the crop from the refuse at lifting time. I let them both go together, and have them sorted over in bad weather by aged employés who cannot then work out of doors. Enough for some time should be stored in a cool shed and covered with dry Bracken or bags in case of frost, the remainder being clamped in the ordinary manner. If the tubers are wet when lifted do not cover down at once, but allow an interval of a few days for the sun and air to pass through and partially dry them, as under such conditions they keep much better. A good old plan is to insert a Seakale pot at the top of the clamp to act as a conducting shaft for fresh air, this being blocked up during frosty weather with Fern or straw, and left clear in mild weather. Of course, where there is plenty of spare cellarage the labour of clamping is saved, although in mild winters these places sometimes become almost too warm, the tubers losing flavour in consequence. No better place than such can be had for storing the seed tubers, as they can then be looked over at will, any decayed ones being easily detected. Where Schoolmaster and other autumn sorts are exhausted, Magnum Bonum, if from a light soil, may now be used. Those from stronger land, the tops of which were somewhat green when lifting took place, will be all the better for lying several weeks longer before being used. Emperor always eats best during the early spring months, as does Gloucester Kidney, one of the best field Potatoes which can be grown and an enormous cropper. Where Regents are grown, clamping is not advisable, as, being liable to disease, they should be stored where they can be frequently examined. Early forcing kinds, such as Sharpe's Victor, Ring-leader, or Mona's Pride, which will be wanted for starting in pots, boxes or hotbeds about Christmas-time, may be placed in shallow boxes on a wet day, arranging the tubers on their ends with a little leaf-mould under them. If the sprouts get too forward they can be removed before they deprive the tuber of its vitality.

**FORCING ASPARAGUS.**—It will now be necessary to collect large quantities of leaves from parks or woods, preferably Oak and Beech, for use in forcing all kinds of vegetables in winter and spring. Asparagus and Seakale will be the first to need attention, and where the permanent beds are furnished with pigeon holes, spaces between the beds may be filled with leaves and stable litter about the second week in November. Use three parts leaves to one of litter, and tread very firmly at intervals as the material is thrown in. The surface of the beds must also be covered with 6 inches or 8 inches of short litter. Where these exist the best plan is to force half the beds one year, resting them the year after. From age or other causes, permanent open air beds sometimes deteriorate, and in such cases the best way is to lift the roots and force them by means of ordinary hotbeds. Make up the bed about 4 feet high at the back, sloping somewhat to the front, and when the heat has declined sufficiently, cover the surface with several inches of leaves and place thereon the roots, covering them with 3 inches of fine loamy soil. Thrust a testing stick or bottom-heat thermometer into the bed and cover the glass with Fern or straw. The same bed can be made to answer for a second batch of roots by renewing the linings, although, of course, by preparing a second bed soon enough, a blank in the supply is prevented. A very suitable place for forcing such roots is the pit of a Cucumber or Melon house, where by turning a bottom-heat valve a comfortable heat can be secured. A top-

heat of from 55° to 60° will be quite high enough, as if more is given, a spindly, tasteless growth will follow. Asparagus forced in such places is much benefited by applications of manure water once a week after growth has commenced.

**RHUBARB,** if required very early, must soon be lifted and exposed for a fortnight to sharp frosts, it starting much quicker and stronger after such a process than when lifted and placed in heat at once. Many experience much difficulty in obtaining early supplies, simply because they try to force unsuitable varieties. The best Rhubarb for the purpose is undoubtedly Prince Albert. It is small compared to many other sorts, but the colour is good and flavour delicious. A Mushroom house is a capital place for bringing on early lots, merely placing the roots on the floor and covering them with leaf-mould. If in close proximity to the hot-water pipes so much the better, although it is not wise to place them directly over them. It will be as well to dig round some more roots intended for secondary forcing batches, leaving a narrow trench open for the entrance of frost. The next lot wanted for lifting will be sufficiently ripened naturally by the time they are wanted.

**GREEN VEGETABLES.**—These will now be fairly plentiful, and will consist of the earliest planted Coleworts and Cabbage sprouts, resulting from old spring and early summer varieties headed close down at the beginning of August. Cabbages also which were sown specially for furnishing nice solid heads just as the frost is making its appearance will be tender and delicious. By the use of these, Savoys and Brussels Sprouts may be left alone for a short time longer, as a few rather severe frosts are really needed to impart the flavour so much appreciated in these two useful vegetables. Where, however, any early sprouts are becoming too large they may be gathered now and cooked as Cabbage, as if left they will only become tough and strong flavoured. If any late heads of Walcheren Cauliflower are likely to be injured by frost, lift the plants and lay them in moist soil or leaf-mould in a dry, cool shed. Autumn Giant or any early heads of Self-protecting Autumn Broccoli which, owing to the great heat a fortnight ago, have turned in before their usual time, may be treated similarly.

**ROOT SHED.**—This should now be got ready for the housing of all roots as lifted.

J. CRAWFORD.

### FRUIT HOUSES.

**PINES—FRUITERS.**—The season so far has been favourable for plants finishing their fruits, as the weather during last month was warmer than usual at that date. There is no season of the year that these fruits are more valued than in mid-winter, and the best culture possible should be given to get good finish. More care will be necessary, avoiding extremes as far as possible, as sudden changes either in heat or excess of moisture soon affect the fruit. The temperature should now range from 70° to 75° at night, with a rise by day of 10° to 15°, admitting air during bright sunshine, and at closing time thoroughly damping all parts of the house. A slight dowing overhead if plants are in a robust condition and the fruit swelling freely may be given, but care must be taken not to wet the crowns; indeed, the syringe must now be given a rest and the house kept moist by damping floors, walls, and vacant places. Keeping the atmosphere well charged with moisture will be preferable to syringing overhead at this season. Bottom-heat will need to be brisk to get good fruit, and though it is not advisable to be frequently adding to the fermenting material at this period of the year so as to cause a check, the temperature should not fall much below 90°, and if new plunging material is required, it is well to prepare it in advance, so as to add it to the bed at the first favourable opportunity, doing the work as quickly as possible. With hot-water pipes there is far less difficulty, and if possible winter fruiteders should be grown in houses treated in

this way. Moisture in such houses will be more necessary, as the roots dry more rapidly. It is advisable when watering at this season to examine each plant carefully, also to avoid as far as possible water lodging in the axils of the leaves. Plants colouring their fruits will not require further watering, and the house should be kept drier. A small pit can at times be afforded them: by this means more air can be given the plants and the flavour will be much improved. Plants with fruit fully ripe may be transferred to a warm room or any dry house. Treated thus they will remain good a considerable time. Plants intended to give fruits later should now be treated liberally if they have been rested or given a check to cause fruits to swell at a dull season of the year.

**SUCCESSIONS AND SUCKERS.**—The large plants of the first-named will probably include the best of the Queen section and those intended to start in December or early in the year. To get the best results different treatment must be given from that advised for fruiting plants. A check is now necessary, the season having produced finer growth than usual. It is well to rest gradually to get good results next season. Less heat and moisture will be necessary, syringing overhead should cease, and thorough dryness at the roots is not advised. Only sufficient water should be given to keep the roots active. The temperature should not exceed 65° at night; indeed, with the thermometer in the open under 40°, 60° will be ample, with an increase of 10° by day, airing freely in suitable weather and using as little fire-heat as possible, relying upon sun-heat during the day. The bottom-heat should likewise be low; if the same as advised for the day it will be sufficient, as the plants start much better when grown as quietly as possible from now to January. I have, to save hard firing in frosty or foggy weather, used mats and waterproof covers over the glass, and found great advantage in doing so. The plants require less moisture when treated thus during their rest. Suckers at this season will take little time, but I do not advise starving the plants in any way, as by growing suckers well fruited are soon obtained. The plants during the summer months often have to be grown in frames and shifts made to give them a start in places heated with manure. Such plants should now be housed in their winter quarters and the treatment varied. Strong early-potted suckers may get the warm end of the house and be given more room and moisture in the way of weak liquid manure if the pots are full of roots. Although late to advise shifting, any specially requiring it may be attended to and given additional warmth when placed in their fruiting pots, watering carefully for a time. The temperature for the plants such as were potted in the summer may be 60° at night, 10° higher by day or less in cold, sunless weather, keeping the plants as near the light as possible and ventilating freely in fine weather. The bottom-heat need not be great and should not fluctuate; 70° to 75° will be sufficient for the next three months, for plants potted at time named as these will not require a shift for a time. Suckers from Smooth Cayenne and other winter fruited should be potted up and plunged in a brisk bottom-heat.

**FRUIT TREES GROWN IN POTS.**—The trees grown in orchard houses will now be in the open, and if forced will ere this have lost their leaves, having been plunged for some weeks in a sunny exposed position. With regard to their removal indoors, much depends upon the condition, age, and when required to force. There is often a lack of house room for such plants, as Chrysanthemums require shelter, and the orchard house when heated is a splendid show house for such plants. The pot trees are benefited by a good rest if they do not get water logged after being top-dressed or repotted. In no case do I advise turning out trees and letting them take their chance till required to force. The roots soon suffer if not protected, and large trees if unduly exposed lose a large portion of their small fibrous roots, which are just the ones required to build up a sturdy fruitful growth. If not yet done, there should be no delay in repotting or top-dressing, and in doing

the former if the trees have reached the full pot limit available, a good portion of the drainage and bottom soil should be removed, using a pointed stick to remove the old soil to make room for the new. In repotting, use clean drainage, good heavy turfy loam, with such aids as bone-meal, old mortar rubble, and wood ashes, potting as firmly as possible, and taking care that heavy rains do not saturate the soil till the roots are working freely. Should the trees be at all backward, it is well to house, giving abundance of air till forcing commences. Large healthy trees should be plunged in fine ashes well over the rims of the pots, and be quite free of drip from trees or buildings. The surface should be protected from heavy rains. Now is a good time to thoroughly cleanse all trees, and in case brown scale and other pests have obtained a foothold, now is the time to get them dislodged. I advise painting badly-infested trees with a mixture of lime, soft soap, sulphur, and clay, first scrubbing the old wood with soft soap and warm water. Cherries require much care in cleaning, also Peaches and Nectarines with prominent buds, and no time should be lost in doing the necessary work. Pears and Apples are at times barren when grown in pots simply through excess of food and gross wood. The latter can be prevented by omitting the bone-meal and manures of all kind, ramming hard and using chalk or old mortar rubble in the compost.

**POTTING UP NEW TREES.**—It often happens that trees grown in pots in the orchard house get too large, and are not so fruitful as smaller trees. Now is a good time to select Peaches, Nectarines, Cherries, Apples, Pears and Plums, potting in the material advised above and well firming the soil, in all cases being particular that the drainage is perfect. In selecting trees it is well to obtain those grown on an exposed site; these will be short-jointed and the roots less strong than in highly-fed trees. Shorten back strong roots and use small pots at the start, the difficulty with pot trees being that they soon get too large. After potting, the trees should be plunged, as advised for older trees, in an open place. In no case should manure be used unless the soil is very poor. As regards size of pots, much depends upon the variety; 10-inch to 12-inch pots are suitable at the start. It is well to have a reserve of young trees, as large ones may be given a rest in the open if desired and useless ones destroyed.

**AUTUMN AND WINTER FIGS.**—The Negro Largo is grown for winter or late autumn supplies, and in pots for this purpose there is no other variety so suitable. The trees will have been exposed freely up to a certain date, this depending upon the season the fruits are required. The trees to fruit freely will require great care. A moderate crop should be preferred, well thinning out weak shoots and stopping strong ones, giving food freely if the fruits are swelling, with a genial day temperature of 65° to 70° and 10° lower at night. Only small supplies of water overhead in dull weather should be given, as excess will cause rust and fruit-dropping. With ripe fruits more ventilation will be required and only a little water if the trees are plunged. Trees just starting should get assistance in the way of bottom heat and every ray of light possible, washing the glass and cleansing the house before starting the trees. A slow heat for the roots, such as fresh tree leaves and litter mixed, will be better than a strong one. If the hot-water pipes can be used for the purpose, do not place the pots in direct contact with them. Placing thick turves over the pipes will check strong heat.

G. WYTHES.

**Cottage flowers.**—Fine flowers in Northumberland cottage gardens are fairly plentiful, but one thing deserving of special mention is a hedge of Mme. Desgrange Chrysanthemum, which makes a perfect dividing line between the vegetable quarters and a flower garden in a roadside cottage at Alnwick. With a few more fine days this hedge from a short distance would look like a snow-drift. The gem of cottage gardens, however,

that came under our notice was one on the Lilburn Tower estate. The house was only one storey high, and a plant of Rose La France reaching up to its eaves had numbers of its great sweet drooping flowers. Canary Creeper and climbing Nasturtiums concealed the rest of the wall in a tangle of flower festoons, and Dahlias told of good cultivation both by the stature of the plants and the profuse display of bloom.

## FLOWER GARDEN.

### A NEW WAY TO GROW MICHAELMAS DAISIES.

I USE the term "a new way" in this case because I have neither seen nor heard of it before; but as I have come at my facts from an accidental occurrence which in a striking way showed an improvement both in scenic effects and better condition of the flowers individually, it is not unlikely that others may have made similar observations, and even acted on the hints afforded. All the Asters may not lend themselves so well to the plan, but with at least a score of the finest that will, that does not matter much. To describe it in the fewest words, it is to bend in an orderly way the tall growths just before the flowers begin to open to within a foot, or less, of the surface. Few would credit the difference for the better which this makes unless they had seen it, and I think the "reason why" is obvious after all. I have tried it with not only different plants, but with stems of the same plant, *e.g.*, some laid and some left erect, and this method is at once the most conclusive and striking to my mind, as showing the advantages of the plan. The laid stems produced the larger flowers and of brighter colour, and they came earlier and lasted much longer. Of course it is not suggested that all Asters should be treated so, for in some positions we want the upstanding effects, and besides, the surroundings otherwise might not either afford the space to bend them down and around or allow the flowers to be seen to advantage if they did afford such space. Where I think the idea will best come in is in making special plantings of lines, beds, banks, or groups of Asters only. For instance, imagine a mass of the pale blue Robert Parker, the dark blue Archer-Hind, or even the small-flowered cordifolius elegans and the delicate Diana so bent or trained that their myriads of flowers would form a dense mass, 18 inches from the surface, so managed in the pegging that hardly anything but flowers could be seen, all improved in quality as stated. I say, imagine this, but you scarcely can, so much will the aspects of these plants be changed, for, mark you, they are all taller than we would wish when grown in the ordinary way. I do not overlook that these and nearly all the Asters have a pleasing habit of forming noble panicles in the erect form, which, for cutting, could never be improved; but I am now speaking more of garden effects, and the way the laid stems fill out and the branchlets turn skywards in a few days after being pegged clearly show us certain capabilities that in some circumstances might be turned to good account.

By this bending-down system you at least save the flowers in a great measure from being battered to pieces by high winds, and however you stake and tie—which always have to be done for some tall and top-heavy sorts and which as certainly take from the beauty of the specimens—it is but a poor measure against the stormy weather usual at Michaelmas. Then, again, in some exposed gardens the tall Asters are im-

practicable, but by this bending-down method there need be no fear whatever.

The way to do it is to simply get a quantity of hooked sticks 2 feet or less long, bring the stems forward and catch them down to within a foot of the ground, distributing them evenly over the surface to cover; then the more backward plants should be brought so as to overlap the bare stems of the front row, and so on. In four or six days the heads will adjust themselves, the branchlets facing upwards and going out laterally. This should be done, as already hinted, some little while before the flowers begin to open, care being taken not to snap the more brittle stems, such as those of the cordifolius group.

To my mind this is all worth the pains because of the better size, colour and duration of the flowers, but it occurred to me that at the same time diverse garden effects might come in too by the pegging-down process.

Woodville, Kirkstall.

J. Wood.

**Disease in *Lilium candidum*.**—A few weeks ago I came across the finest lot of *L. candidum* bulbs that I have ever seen. They were simply enormous as well as solid and heavy. I made particular inquiries as to the source from which these imported bulbs were procured, and eventually ascertained that they had been grown in the neighbourhood of Toulon. The question then occurred to me: Is it possible that these splendid bulbs are the produce of plants affected by the disease, and can it be that this plague only attacks imported bulbs after their change of climate? I have no knowledge of Lily culture in France, but perhaps some correspondents have seen Lilies growing there, and could inform us whether the disease is as prevalent in the south of France as it unfortunately is in England. "H. H. M.'s" interesting letter (p. 115) is very much to the point as regards the disease, and I am glad to see that he agrees with me as to its being an importation. Some of his instances of old-established bulbs that had for years flowered well contracting the disease are, however, adverse to my theory, founded on personal experience, that home-grown bulbs, though planted in close proximity to diseased foreign bulbs, do not fall a prey to the epidemic. In my case the lethal spores had not to be carried miles, but only 2 yards—from the row of one hundred diseased French bulbs to an English-grown clump—yet the latter never showed the least sign of being affected and this season is finer than ever. Still, it is quite possible that this immunity may have been but a stroke of good luck. I have tried "H. H. M.'s" baking process, but the disease has so weakened my imported bulbs, that I fear they will be scarcely strong or large enough to bloom next season.—S. W. F.

**Winter Violets.**—Violets in many places are this year in a pitiful condition, owing to the attacks of red spider, the result of too little moisture both in the atmosphere and at the roots. Plants that are growing here and there in any spare border are covered with spider, while those on specially prepared shady plots are in a much cleaner, healthier condition, this fact showing the necessity, especially in dry seasons, of good cultivation. Mine are not quite so robust as usual, not because they are affected by spider, but because, having been grown on the same ground for ten or twelve years, the roots have partially exhausted the staple soil in spite of the biennial additions of good loam, leaf-mould and road grit. Being the best position I have for my Violets, and intending still to grow them there, I purpose during the coming winter taking out 18 inches of the border, replacing it with the same depth of good new loam and correcting materials; this will again produce a stout, free growth. Light frames or pits quite free from drip are necessary if the plants are to do well through the winter and spring months, and full exposure during fine

weather. When cutting winds prevail the lights must be drawn up and tilted, or the young foliage will suffer. I always give a good soaking after planting, repeating it in a few days' time, after which I never water till February. I have read of those who mulch their frame Violets with cocconut fibre, in order, as they think, to prevent damping, but I should not care to do it myself, as it must shut out air and what sun's warmth there is in winter from the roots. Abundance of fresh air and occasional surface-stirring and removal of all yellow and decaying leaves are necessary. Those whose plants are crippled with spider should dip each one in sulphur water before planting, but they had better throw them away in spring and obtain a fresh stock of runners from some other source.—J. C.

***Hydrangea hortensis*.**—In the autumn the display afforded in the west country by the great *Hydrangea* bushes in full flower is very striking. In one garden they are to be seen lining the drive from the lodge to the front door. In another, great masses of bloom stand out from the dark evergreens of the shrubbery. In a third, the shady woodland paths are brightened by a profusion of their massive flower-heads. In some situations the flowers lose their usual pink shade and are of a light blue colour, which change is generally attributed to the presence of iron in the soil. It may often be noticed that on the same plant both pink and blue flowers are produced as well as some of intermediate shades. The brightest blue that I have ever seen in *Hydrangea* blossoms was borne on plants growing along the edge of a cliff overlooking the sea in the vicinity of Start Point, South Devon. They were situated at the verge of a gravel path and were exposed to the full glare of the sun and the force of the landward gales. The hue of the flowers was almost that of the Forget-me-not, and the plants were smothered in bloom.—S. W. F., *Torquay*.

#### LILIUM HARRISI.

WHERE it is intended to lay in a stock of this Lily for flowering in pots no time should be lost in obtaining the bulbs if this has not already been done, for even if they are not required for early flowering it is much better to pot the bulbs and let them root and grow gradually than it is to keep them in a dormant state too long. It should be borne in mind that most of the immense importations from Bermuda reach this country within a limited period; hence, if the bulbs are not purchased till Christmas or thereabouts—as is often the case—they will have passed some months probably on shelves in a dealer's warehouse, and in that time a great waste of tissue takes place, and consequently the plants cannot possibly be as vigorous as they would be if potted at the proper season. Where they are not unpacked and laid on shelves, but allowed to remain in the boxes, roots are pushed forth from the base of the bulbs into the sawdust generally used for packing them, and in trying to disentangle the mass many of the roots are broken and considerable check thereby given to the plant. Another drawback is, that if allowed to remain in the boxes too long the stem is pushed out, and being so brittle it is easily injured in unpacking. If the bulbs of *Lilium Harrisii* are potted and placed in a cold frame the lights of which are only used to ward off the heavy autumnal rains, they will root slowly and surely, and may be had in flower nearly, if not quite, as late as those kept out of the ground so much longer. Where required for early blooming, the bulbs of *L. Harrisii* should of course be potted as soon as possible, so that they will at once commence to root, for it is useless to attempt to force them till the pots are well filled with roots.

This caution concerning the detrimental effects of potting *L. Harrisii* too late in the season might well be applied to all other Lilies, and indeed to bulbous plants in general, for one sees bulbs of all kinds of Lilies exposed for sale long after the period they should have been in the ground. *L. candidum* in particular is harshly dealt with

in this way, for if moved at all this should be done as soon as possible after flowering: whereas one may see them in a dry state till the new year or nearly so. It is of course useless to expect such as these to flower. Freshly imported bulbs of the Japanese *Lilium auratum* may often be had in pretty good condition till spring is well advanced, and the different dealers frequently receive applications for dormant bulbs till nearly midsummer. Hyacinths, Tulips, Narcissi, Snowdrops and such things, which should be planted or potted early in the autumn, are frequently ordered from the dealers about Christmas, or even after, when if the goods are supplied the display will be of course unsatisfactory to both vendor and purchaser. H. P.

#### FLOWER GARDEN NOTES.

**PLANTING HERBACEOUS BORDERS.**—The arrival of frost and the necessity of making a clean sweep of all dead and decaying flowers will enable the planter to get to work on herbaceous borders as soon as possible, with the view to get most of the work finished before severe frost puts an end to operations of this kind. The notes that were taken from time to time all through the season in connection with the inmates of these borders will now be of the utmost value towards strengthening weak points and increasing the quantity of specially good things. This latter work is imperative, for the really good things are so numerous and their propagation as a rule so easy, that the annual weeding out of indifferent subjects is a first consideration. Again, all things that are the better for annual lifting and replanting should receive attention and all stragglers be taken away. Borders of this kind should be planted as naturally as possible, but at the same time one does not want absurd mixtures, and to allow one species to encroach unduly on another will be greatly detrimental to the weaker plant. When replanting the front of the border, for instance, with such things as the Hepaticas, Heucheras, or the stay-at-home Campanulas, a wide berth must be given to straggling *Viola*s or the trailing Bell-flowers, as, unless a sharp look-out is kept towards the end of the season, the plants of more compact habit will be completely smothered. Due regard should also be given to the height of the different species, and if any mistake has been previously made it should be rectified. I do not mean that the planting should be severely regular to resemble a shaven slope; this is altogether a mistake, a broken outline being one of the most pleasing features, but that very tall subjects should not find their way to the front to the prejudice of their immediate neighbours. If groups of plants having bulbs or corms are to be used on herbaceous borders the spots should be carefully marked by labels that are not likely to be displaced, and I have found it a good plan in such cases to indicate not only their whereabouts, but the size of the clumps. This may be done by placing the label in the centre of the clump and noting thereon the number of inches, twelve or eighteen, as the case may be, so as to give an idea of the edge of the same, and if care is taken in the planting, an accurate estimate of the proximity to other things can be formed. Again, a nice balance of colour, not a preponderance of one particular shade, should receive careful consideration, a remark that would apply to all parts of the border. Masses of Carnations and Pinks should be relieved by nice shades of blue, and the perennial Sunflowers broken by the softer hues of the Starworts; the best foliage, too, as supplied by the Pyrethrums, *Spiraea filipendula*, and others of a similarly graceful habit will act as an admirable foil to groups of bright colours. The advisability of so planting as to give a level balance of flower right through the borders at all seasons of the year can hardly be over-rated, that is, not to put too many spring, or summer, or autumn flowers together, so that in given spots there is a mass of bloom at one particular time and little or nothing for the remainder of the year. A last note of warning will be to be always chary of using too many

short-lived flowers, such, for instance, as Columbines, Pionies, and the like. They are very handsome for a time, but the fact that they are so soon over considerably handicaps their usefulness. Also anything that is constitutionally weak or is subject to disease, as, for instance, *Lilium candidum*, should be sparingly used. A collapse at an unexpected moment is awkward, and leaves a gap it is not always easy to fill.

**SPRING FLOWERS.**—Beds cleared of summer bedding plants that are to be utilised for a similar purpose another year may be planted with spring flowers that are waiting removal from nursery beds. Wallflowers are certainly the most useful of spring flowers, and the variety of shades has undergone considerable improvement within the last few years. It is very seldom that one has the misfortune to lose Wallflowers wholesale as we did last spring, the percentage saved being barely five in a thousand, and it was dealt out impartially, no one variety coming out of the ordeal better than others. Polyanthus may be used largely if plenty of time is available in late spring to clear them away and prepare the beds for summer plants. A great point in the planting of these temporary things is to regulate the work in such a way that beds required early another year may be filled with plants that are quickly over or the sacrifice of which whilst yet in flower is not much regretted. A good strain of Polyanthus is, on the other hand, sometimes at its best, especially in a rainy season, at the time when the earliest summer flowers should be put out. E. BURRELL.

Claremont.

**Cosmos bipinnatus.**—As a late-flowering annual, this and its charming white variety deserve attention. Elegant in its leaf formation, though a little irregular in growth, it is an excellent subject for blooming late in summer, and Mr. E. Beckett employs it at Aldenham House Gardens largely in a long border of mixed annuals. The species has rose or purple, small, chaste, Dahlia-like blossoms, from their elegance well adapted for cutting, those of the white variety forming a very pleasing contrast. Seeds can be sown in spring in a gentle warmth, and plants grown on to put out in June to bloom.—R. D.

**Notes on Lilies.**—In an article on these a correspondent has drawn attention to *Lilium Melpomene*, a variety of *speciosum*, which he says was brought out by Mr. Hovey, of Boston, U.S.A., and was stated to be a cross between *auratum* and *speciosum*. Mr. Hovey never stated this to be the case, and your correspondent has confounded another Lily with it. Mr. Hovey raised a number of seedlings from *speciosum*, and nine of these were selected, which he inscribed to the Muses. Of these, *Melpomene* was the only one of the nine that seemed to him after some trial to be worth preserving, and it was propagated and sent out as a variety of *speciosum*. Its bold and distinct colouring was very attractive. The only one of the varieties in the catalogues which approached near to it was *superbum*, and I very much fear that that variety was substituted in many instances for it; in fact, I have found this to be the case, and a very strong-growing *Melpomene* I have found to be little more than *superbum*. It is no wonder, then, that your correspondent could trace nothing either in the foliage or the flower of the *auratum* blood in it. Some years ago, however, there was a variety raised in America by Mr. Parkmann which was evidently a decided hybrid between *auratum* and *speciosum*, partaking of the character of both. This was, I believe, once exhibited in England, though I did not see it, but a coloured plate of it appeared in the *Florist*, and attracted a good deal of attention. A well-known English firm purchased it, and I believe it never could be increased sufficiently for sale, and whether it is still in existence I know not. I have very little doubt that your correspondent has unwittingly confused these two Lilies. It has, however, always seemed to me very strange that no hybrids have resulted from intercrossing these two species. The organs are so large and easily

manipulated, that they would seem to afford no difficulty, but although various hybridists have tried them there has been no result, with the exception of the one above named.—DELTA.

### THE SPANISH SQUILL.

(*SCILLA CAMPANULATA*.)

For gardens where the soil is strong clay there is no bulb more suitable for naturalisation than this. It is much more effective in the mass as well as more lasting than our native wood Hyacinth or Bluebell, and increases even more rapidly than that widespread bulb. Planted among Grass under trees or on wild banks, it will take care of itself and yearly increase in beauty. In the garden where this engraving so prettily shows the growth of this Spanish Squill the original bulbs were planted early in this century, and have now spread far and wide, scattered in a curiously happy way over several acres of semi-wild banks, where in spring, especially in May, they make a lovely picture. Of later years considerable quantities of London Pride and mossy Saxifrages have been planted in large and irregular masses with an exceedingly good effect. The combination of soft pink, lavender, blue, and clear white

summer, which can be compared for elegance with *Gypsophila paniculata* only. I think it can beat every other plant for covering summer-houses, pillars, trellises, bowers, walls, &c., the foliage being as green and fresh in October as in July. The fruit is a small green berry, bright scarlet when ripe, rarely produced. It is of the easiest culture. In November cut down the stems and leave alone until the following spring.—D. GUIHENNEFF.

### NOTES ON HARDY PLANTS.

**Aster Novæ-Angliæ roseus.**—This is perhaps the tallest Michaelmas Daisy of the New England group, not that its stature of 5 feet to 6 feet is a very commendable quality, but it may be useful to point it out as fitting the plant for the back line of the herbaceous border. It is also perhaps the least seen of its class, though the rosy flowers are both abundant and distinct. Perhaps I should mention the honey-like fragrance of the heads and that it is earlier than *ruber*.

**Aster Novi-Belgii Ella.**—This is a new variety that occurred by chance in the gardens of the Rev. Wolley-Dod. It is a striking sort, very vigorous, with dark foliage and stalks 5 feet or more in height, coming in early with its very large and full flowers. With the exception of two or three others, such as *Thomsoni*, the *Amellus*

The Spanish Squill (*Scilla campanulata*) naturalised. Engraved for THE GARDEN from a photograph sent by Mr. E. H. Woodall, St. Nicholas House, Scarborough.

under the fresh canopy of green leaves, renewed each spring, is a delight to all lovers of woodlands and such vernal joys.

Scarborough.

E. H. WOODALL.

**Withania origanifolia** (belonging to the Nightshade family) is scarce in gardens. It is widely spread throughout Brazil, Buenos Ayres, Monte Video, Patagonia, &c. It has been found on the plains of the Pampas 500 to 600 miles inland, rambling on the ground amongst bushes and shrubs. It was introduced about 1825. If accidentally seen in a botanic garden it looks very much like a poor useless weed; but when properly cultivated it is one of the best and most useful climbers we can introduce into gardens. From its long, fibrous, perennial roots spring in March and April numerous slender stems, which attain during the summer a height of 6 yards to 10 yards. These stems are covered with small, ovate or rhomboid, short-petioled leaves, the whole plant (leaves and stems) being of a very bright shining green colour. From July till frost comes the plant is literally covered with small, minute, nodding, pure white, sweet-scented flowers, which are produced in great profusion. The contrast of the white flowers upon the dark green elegant foliage produces a most graceful, compact mass from top to bottom of the plant during the whole

group, and *Novæ-Angliæ præcox*, its flowers are of the largest and also the fullest in the ray, the colour a pleasing mauve.

**Aster Novi-Belgii Nancy.**—This is another newly-selected seedling of Mr. Wolley-Dod. Its stature with me in dryish light soil is 3 feet to 4 feet, and it is one of those kinds which show their abundance of flowers all, or nearly all, at once. In this case the heads of bloom are of medium size, but it is the fulness of the rays and silvery mauve tint that render the abundance of flowers so conspicuous. It comes rather near to a kind I have grown for ten years or more as *decorus*. The heads, however, are a little larger and the rays not quite so sharply defined as in that old dainty variety.

**Wild Michaelmas Daisies.**—We are now getting accustomed to new and improved kinds, and it may be useful as well as interesting to mark progress sometimes. It is no unusual thing to forget what we have left behind, and in the case of some flowers we may well do so, but with the Asters the past may help the future, especially with those who desire to know more about types or groups. From a strictly florist's point of view, too, it may be well to recall the old forms in order to see the great progress that has been made in a few years, as well as to urge us on in the developing of those improvements of which the perennial Asters are clearly capable. These

thoughts occurred to me as I looked over a lot of wild forms of various types that reached me nearly two years ago. We often hear from our American friends of how showy the "fall Daisies" are. What would be the effect if similar masses of the better garden kinds could be seen? Seedlings are everywhere flowering this year, and nearly all are such that one does not care to pull them out, at least till the flowers are done, and many are worth a place and a name. Even on old walls I see stunted specimens flowering prettily. The effect is vastly superior when one sees large groups of one kind.

**Polygonum sphærostachyum.**—This dwarf and knob-rooted species often flowers a second time in the autumn; indeed, speaking from a five or six years' experience of it, I think it never fails to do so in the case of plants that are happy, *i.e.*, in moist vegetable soil and full exposure to sunshine. The spikes of flower on plants but 9 inches to 12 inches high are 2 inches long and of the intensest vermilion-scarlet, a somewhat different shade at this season from that of the longer days of June, but for that matter the individuals vary in themselves, and you may cause them to vary still more by placing them under different conditions culturally. The plant is hard to kill, but you may easily influence it in bloom colour or to bud blindness by wrong treatment: the one essential of all is moisture. Treat it as a bog plant in the less swampy parts. I find it does quite well in the bottom or dish-formed parts of the rock garden.

**Shortia galacifolia.**—It is well worth while to grow this pretty plant in patches for the sake of its rich bronzy or red-brown foliage as seen at the present season, and it is a feature all the more valuable because the foliage is persistent all the winter and retains its rich warm tints.

Woodville, Kirkstall.

J. Wood.

#### MICHAELMAS DAISIES.

HARDY flowers are largely grown in the gardens at Ham House, Richmond, and at this late period of the season perennial Asters form a prominent feature. Many were on the 12th inst. long past their best, but some others later were in beautiful bloom. How valuable are hardy flowers that only bloom so profusely as these do during October, but are then at their very best. It was not difficult to make up a fine nosegay of these fresh, charming Daisies with yet late, though straggling Sunflowers, of which one with tall and naturally late flowers of medium size and single, which came from Miss Jekyll's garden at Godalming, is, for the season, the best. The pretty *Eriogonon philadelphus* is also blooming freely, because being hard cut earlier, it flowers again in the late autumn. A few charming blooms are gathered from *Chrysanthemum cinerariifolium*, an exceedingly pretty variety, and the lacinated form of *C. maximum* also gives a few late flowers. Then the pretty blue *Echinops Ritro* has thrown up many late flowers, and these give to the bunch very welcome colour. So also do the perennial *Gaillardias*, the flowers being of more agreeable dimensions than in the summer. But with the exception of the best late Asters most hardy things are practically over, a few blooms furnished being from late growths or side shoots. Even *Chrysanthemum uliginosum* is practically over, for the recent winds and rains so beat and battered the large single blooms, that hardly a perfect petal is left. This is for so late an autumn bloomer not at all satisfactory, because the flowers so soon exhibit evidence of collusion with each other, being so tall and loose-stemmed. Of annuals very pretty and almost alone, some plants of *Chrysanthemum tricolor* and *Dunnetti* gave really charmingly fresh, bright flowers, leading to the conclusion that these sown later than usual would be particularly useful for late cutting. It is very evident, however, that out of the great mass of Michaelmas Daisies grown here and elsewhere, the most useful, as well as the best generally, are those which bloom late.

Such hardy flowers at their very best are brightest in October, are far more useful than are earlier ones in September, especially when other flowers, hardy and tender, are in profusion. Of those at their very best at Ham House in the middle of October were *Aster cordifolius*, a very graceful and elegant variety, blooming to a height of 4 feet. The flowers are small, of a bluish white colour, borne on large branching spikes or heads in wonderful profusion. Anything more charming for cutting could hardly be found in the family. Very pretty indeed is a form apparently of *ericoides* growing 20 inches in height, flowers white, just like small, natural Daisies, also of spike form and branching very freely. A pleasing pale blue-flowered variety is *A. Novi-Belgii* Flora, height 5 feet, and carrying a mass of flowers. *A. Nova-Angliæ* *rosens*, *ruber*, and *pulchellus* are also very fine, tall, and attractive sorts, in the height of their beauty. *A. grandiflorus*, 3 feet in height, flowers large and deep purplish blue, is one of the latest, only just opening its blooms. This should make a capital variety to grow in pots for flowering late in a greenhouse. A very pleasing variety is a rather taller form of *ericoides* than the one previously mentioned. Michaelmas Daisies seem to be very variable, and some need to be grown for two or three years to reveal their true character. A. D.

**Perennial Gourd** (*Cucurbita perennis*, Asa Gray; *Cucumis perennis*) is seldom met with in gardens. The roots are large, fleshy, whitish, of the size and shape of a Beetroot, the stems annual, climbing or trailing. The male flowers, large, yellow, with a scent of Violets, are produced from July until frost comes; the female flowers appear much later, sometimes not at all. The fruits are globose, the size of an Orange, spotted or variegated with white and yellow when ripe. If allowed to trail on the grass it forms an immense circular bed or carpet 10 yards to 15 yards in diameter; planted at the foot of a tree and allowed to climb into the branches, the stems soon fall and spread all round in a most graceful manner. It is also valuable for covering walls, trellises, &c. The roots will stand our most severe winters. It prefers a very rich, deep, well-manured soil—calcareous if possible. In autumn, when frost has destroyed the leaves and stems, it is well to cover the roots with a heap of sand or dry leaves. The best time for planting is March or April; it increases easily from seeds sown in spring. Keep seedlings in roomy pots, winter under a cold frame, then plant in the open ground. The roots produce numerous suckers, which can be used for planting exactly as seedlings. It is a native of North America, Texas and California, and was introduced about 1840. In the *Jardin des Plantes* in Paris there is a fine specimen trailing on the grass. It is very attractive, but never produces fruit, whilst other plants covering the back of a house fruit every year.—D. GUIHENEFF.

**Gaillardias.**—*Gaillardias* are among the most useful of our hardy border flowers. They are each year becoming more and more popular, and are simply indispensable where cut flowers are needed in quantity during June, July and August. In fact, the same roots will continue to throw up not a few blooms right into the autumn. One of the chief recommendations of the *Gaillardia* is its power to endure a long period of drought. All through the tropical summer of 1893, and again during the present season, *Gaillardias* were to be seen on all hands erect and covered with flower, while many of their herbaceous associates were prostrate and half dead. The present month and during the first half of November is a good time to plant, giving them, if possible, a somewhat sandy soil, although really they are not fastidious either in regard to soil or situation.—J. C.

#### SHORT NOTES.—FLOWER.

**Dahlia Mrs. Peart.**—Can any reader inform me if this Dahlia ever gives a perfect blossom, *i.e.*, without showing the yellow centre? At the Dahlia

show at the Crystal Palace last month it was not very much exhibited, and not at all in the best stands. I do not remember seeing any blossoms which did not show the yellow centre more or less.—C. W.

**Aster salicifolius.**—Among the most charming of Michaelmas Daisies is the above-named. I noted a fine bushy specimen in September literally covered with bloom. The individual flowers are tiny and bluish-coloured. For the decoration of vases and the like its branches of bloom are exceedingly dainty.—S.

## KITCHEN GARDEN.

### WATERCRESS GROWING.

A FEW weeks ago I was afforded the opportunity of inspecting some Watercress beds of considerable extent. These beds were situated in the county of Dorset on the chalk, and lay in a shallow valley, through which a somewhat sluggish stream flowed hither and thither among River Grasses, Water Reeds, and Bents. I found that a straight course had been formed into which the stream had been turned, and an embankment constructed between it and the old waterway, not a drop of its water being allowed to permeate into the adjoining Cress beds, which had been made out of the ancient channel of the stream, and were supplied with water drawn solely from the chalk springs that welled up in profusion, and, where these proved insufficient, from Abyssinian wells bored to the depth of from 80 feet to 100 feet. This water, coming from a depth, emerges from the springs and wells at a temperature of 50° throughout the year, which warmth keeps the Cress growing through the coldest weather, the necessity for the rigid exclusion of the cold surface-water which would at once chill the beds and prevent the growth of the Cress being immediately apparent. Watercress culture on a large scale is only possible during the winter and spring months by the use of this warm, pure spring-water, the practicability of producing Cress at this season of the year while using sewage-contaminated surface-water, which report said was a practice in vogue, being strenuously denied. It is candidly admitted that, when the weather becomes warm, Watercress will thrive in any damp situation, but until that period arrives it is averred that there is no chance of the water in which it is cultivated being impure.

The beds are of gravel and are absolutely level from side to side, in order that the water, which is about 3½ inches deep, may flow over all parts with equal rapidity. Should, by reason of springs breaking up or from other causes, the bottom become uneven, the water does not circulate freely, and in some places has a tendency to become stagnant, thus freezing in the winter, and thereby causing the ruin of the Cress and allowing the frogs to spawn in the sluggish spots during the spring. Transverse and diagonal watercourses are kept clear of Cress here and there in order the better to regulate the even flow of the water. The Cress is propagated either by cuttings or by rooted plants, the latter being merely laid down on the gravel with stones on their roots, and the former inserted between the pebbles of the bed. Once a year, sometimes oftener, the beds are renewed. The months during which the bulk of the crop is cut are February, March, April, and May, although a certain amount of cutting goes on throughout the year. The grower to whom I was indebted for my information and my visit of inspection had about 6 acres under Cress in Dorsetshire, and was interested in beds of more than double that acreage in the county of Hertfordshire, from

which latter beds 300 tons have been picked and marketed within the year. The Cress is, for the most part, sent to market in flat, oblong, covered hampers containing half a hundredweight.

The grower has many enemies to contend against, the chief of which is the caddis fly, for which the shallow, gravelly Cress bed is an ideal resort. Armies of these larvæ often feed on the roots of the Cress, when their progress can be marked by the yellowing leaves,

tion has it that the breakfast table of King George III. was daily supplied with Watercress from the neighbourhood of Reading.

S. W. F.

**Celery, Brydon's White.**—There is still room for a good solid, early white Celery that will not run to seed, as early batches frequently do; and in the opinion of Mr. Oliver, of Eslington Hall, such is forthcoming in the variety above named, of which he has had two very fine rows this season,

lent. I would also desire to note the value of these compact growers in such winters as the last, when the larger kinds were much injured, whereas this stood well. I find for late supplies the above will give a good return, as though dwarf, the buttons are much closer together than in the larger kinds.—G. WYTHES.

**Broccoli Snow's Winter White.**—Requiring winter Broccoli in quantity, I have for many years depended upon the above. Of late years, however, I have had but little success, and this season I am worse off than ever. I am aware one must make allowances for the exceptional weather experienced through August and September, the heat being great, with slight rainfall. On the other hand, all vegetables have suffered more or less, and I do not see why this Broccoli should fare worse than the Self-protecting. An early lot grown for November and December supplies is poor, and many plants have failed to form heads, and what are formed are totally unlike those of Snow's I have grown in former years. This variety was noted for its medium-sized, pure white heads, the flower also being well protected. I admit it was not hardy, but those who knew its character and took the precaution to lift as soon as the heads were formed were well repaid by having choice material for the late autumn supply. I have another large quarter planted for mid-winter supplies, and these plants, though from another sowing and different seed, look as much unlike Snow's as I have ever seen. Culture may be at fault, as in such seasons the sowing may have been too early. I usually sow this last lot in May, planting out early in firm land just cleared of winter Spinach or early Peas. Have any readers of THE GARDEN noticed any defects in this variety? I fear the true Snow's is a thing of the past; at any rate, I have not had it of the same quality as I had fifteen or sixteen years ago. Seed firms advertise this variety largely, but is it the original stock? I know that vegetables will soon lose their true character unless special means be taken with the seeding and selection, but I fear another variety is substituted for Snow's. This is a serious matter to the grower, as it makes a gap in the supply at a season one cannot make up the deficiency.—W. S.

**Potato Boston Q. Q.**—Having been favourably impressed with the above variety last season, I obtained about a peck of seed and was disappointed at the results. This year I planted a bushel of seed, putting the rows 3 feet apart with half the distance between the sets, thinking it desirable to give it a further trial. Like "E. M." (page 259), I am much dissatisfied both as regards crop and quality. I admit the soil, like that of "E. M.," is not at all good, but such kinds as *Magnum Bonum* have never failed. Though it is not a good Potato season, the tubers of Boston Q. Q. are of poor shape and with very deep eyes. This I should not mind if the quality and crop were better or as good as stated by "W. S." I have now determined to give up its culture, there being so many good Potatoes one can rely upon.—W. S. M.

**Over-grown vegetables.**—This is evidently a failing of the season judging from remarks made by other correspondents and from my own experience. It is really surprising what luxuriance there is in the several sorts of winter greens, Brussels Sprouts, Savoys and Broccoli when the ground has been so hot and dry for so long a period. A large breadth of Earley's Hardy Winter Green, Cottager's and Sutton's Arctic Kale planted

*Trichomanes radicans.* From a photograph by Miss Willmott. (See p. 316.)

while the extermination of the pest seems to be an impossibility.

There are many varieties of Watercress, but the distinctions are only recognised by the *cognoscenti*, the knowledge of the public being limited to a capacity for discrimination between the dark-coloured winter Cress and the light green, which is chiefly grown in the spring. The eccentricities of fashion may be instanced by the fact, that while in one town the dark Cress is favoured, at the neighbouring city only the light is sought after.

The industry is no new one, certain of the beds now in existence having passed from father to son for three generations, while tradi-

and at the time of our visit much had then been already used. Not a plant had run or shown the slightest tendency to do so, although the heat and drought of September, which were severely felt even in northern gardens, are conditions that often cause premature bolting. Mr. Oliver dug some for our inspection, and the heads were as large, long, solid and crisp as those of later growth would be.

**Brussels Sprout Dwarf Gem.**—Most varieties of Brussels Sprouts have a tendency to coarseness, the huge sprouts being deficient of that mild flavour so much valued in this vegetable. Dwarf Gem may be termed distinct in habit, the plants being sturdy with compact foliage. The sprouts are medium-sized and the flavour excel-

on ground neither dug nor manured this season, and which produced a good crop of Brussels Sprouts last year, has grown more strongly, unfortunately, than any I have ever seen before, and will, I fear, should cold weather set in, be badly crippled. Sprouts are similarly luxuriant and not proportionately early in "buttoning" up, and the heavy rains of the past few days will not tend to mend matters very much. Savoys, too, have a tendency to a large leaf development, so also has Broccoli, but the last-named can be checked by laying where this practice is carried out. During the excessively hot September days there was a very heavy dew deposited on growing crops, and this with the attendant coolness of the early mornings no doubt stimulated the excessive growth complained of. I have not been able to get a satisfactory growth in Spinach for winter use until this autumn; no matter how treated, it absolutely refused to grow strongly in this garden, but at the present time its luxuriance is such as to almost give rise to complaint, fearing the consequences of severe frosts later on.—W. S., Rood Ashton, Trowbridge.

#### NOTES FROM STRAFFAN, CO. KILDARE.

THE gardens at Straffan are worth visiting at all times of the year. Even on the coldest and most dreary day in winter there are green turf and silvery-barked Birch trees, and the glow of crimson Dogwood and of golden or of cardinal Willows beside the river Liffey—here clear and pure as it leaves its native hills. Even in February, with its snow or its Snowdrops under the red-twigged Lime trees, Straffan is more cheerful and hospitable and flowery than many places much milder and nearer the sea. But to see Straffan gardens in April, or May, or in June or July, or in September and October, is to see a flowery and a fertile place sheltered by tree growth through which there are charming views towards the hills beyond. Just now when the Beeches, Chestnuts and the great Limes are putting on their autumnal tints of brown and russet, or red and crimson, or lemon and gold, there is colour everywhere high up against the blue sky or in front of the old red walls. The Roses are not what they were, but veritable jungles of Fuchsias, Dablias and Sweet Peas, and meadows of Mignonette, Rosemary, Lavender, Sweet Verbena and Heliotrope send forth their fresh odours, double-distilled during these almost tropically hot days, far into the mist and moonlight of the balmy nights. Never perhaps was the flower garden quite so brilliant as it has been through these torrid days of sunny autumn. So also the grace of stem and leaf is there, Bamboo, Arundo donax and Eulalias, or Fan Grasses of Japan, and the hundred and one things on wall and in hedge or on bower that go to make up a garden of infinite delight.

Under a blazing sun it is pleasant to watch the speckled trout dart here and there into the cool deep pools, or by the shaded banks of the river while the wood quets call softly to each other in the Scotch Firs or Beech trees near, and the water hens flutter amongst the reeds, and the robins sing again their sweetest of autumn songs, while high overhead the herons wheel and float as they go down to the shallows for their supper from the stream. The flowers may be larger and sweeter and the fruits of more exquisite flavour elsewhere in a thousand gardens, but on these points I firmly believe that Straffan can afford to be silent, as many a feverish and care or pain-worn hospital patient can testify, and this year in particular there is fruit of the best and enough to spare. The small fruits, such as Strawberries, Currants, Gooseberries, Cherries and Raspberries, were difficult to clear off, and now it is the same as to the gathering of the Apples and Pears. And this year the glory of exquisite colour is everywhere on Japan Maples, Tulip Tree and Japanese Creepers alike. Veitch's Creeper, now to be known as *Vitis inconstans*, has been like a crimson curtain, or like the rich dyed rugs and velvets

hung outside the casements in Venice on a festa day. So also the scarlet *Tropaeolum* and its first cousins, the Canary Creeper and the red-flowered tuberous-rooted kind, have all been trying their best to strangle and hide the Roses on the walls.

One specially pretty feature at Straffan is the garden lodge with its Rose and Clematis and Japanese Honeysuckle garniture on the walls and around its windows. Vivid are the Begonias and sweet the white odorous Tobacco and the night-scented Stock beside the open door, and for the curious there is a little wall of choice alpine plants that is an ever-changing, ever-turning page on which there is something written for every day of the year.

In one of the cool greenhouses the Chilean Bell-flower, or climbing Lily of Peru, is this year fruiting freely for the first time here, and there are choice Orchids and Ferns, and rare stove and greenhouse plants under glass everywhere. A strong plant of *Vanda Sanderiana* has a spike of seven flowers of large size and soft and exquisitely modulated colouring. The new *Dendrobium Phalenopsis Schrederianum* is also blooming freely; so also *Ondotoglots* and *Masdevallias* and *Oncidia* of the *O. curtum* and *O. Forbesi* types, while the *Phalenopsis* are healthy and vigorous, a sure sign of the gloriously soft rich floral wreaths to come. Here in one corner is a mossy pot containing a hundred or so healthy seedlings of *Ramondia pyrenaica*; here is the rare Oak-leaved Myrtle and the double-blossomed kind in full flower. *Hedychium coronarium* rivals the finest of Orchids in sheen and in whiteness and in its exquisite perfume. Rarely have I ever come across the dainty little *Davallia parvula* so fresh and dense and mossy as it is here grown, though I have seen it on mossy tree trunks and branches at home overhanging the Bornean rivers and streams. One remarkable specimen of *Hæmanthus Catherina*, bearing nine of its great globular spikes 2 feet to 3 feet in height over its spreading light green Crinum-like leaves, had just gone out of bloom, but a photograph bore testimony to its gorgeous beauty as seen in its glowing hue of scarlet petal and gold-tipped anthers when at its best. So also the flower of the gods from Table Mountain, *Disa grandiflora*, was past its best, but the old spikes showed plainly what a gorgeous display it must have made. One mass of *Lælia anceps* throwing up twenty-nine spikes promises much beauty later on, and a batch of the vivid crimson-scarlet *Begonia Fœbellii* lit up one of the greenhouses with its brilliant floral fire.

Speaking of colour reminds me that on one of the walls here is a young plant of *Vitis hederacea*, supposed to be the common old Virginian Creeper, but its foliage is so enormous that I suspect it is a seminal form. The lower leaves are three to five-lobed, and the largest of the five lobes which I actually measured is 10 inches long by 5 inches wide. The entire leaf is (petiole included) 20 inches long, and from tip to tip of the two central lateral leaflets 16 inches, the colour now being brilliant reddish brown, shading to bright red-crimson. After making all due allowance for a healthy young plant in deep rich soil and a genial aspect, I still think leaves of this gigantic size are remarkable on the old Virginian Creeper.

There is an old enclosed garden at Straffan surrounded by walls and greenhouses, having flower borders and walks around a central grass plot with a dial. Here, amongst the other flowers, is an irregular row of great tufts of the old blue *Aster bessarabicus* covered with their great Daisy flowers, and the purple-blue flowers are again, in their turn, covered with a host of butterflies on sunny days; so that you almost think of the insect life of the tropics as you see them fluttering and dancing and basking in the sun. They are mostly the orange and black tortoise shell variety, but amongst them, in more regal colouring, are great red admirals. Then at night, or rather in the gloaming, come the humming-bird hawk moths, brisk and alert, to rifle sweets from the long-tubed flowers of the white-flowered

Tobacco or the Petunias, or from the Japan Honeysuckle on the walls.

I have seen Straffan under many phases, scathed by a bitter winter's frost, and as flowery and sweet under a genial summer's sunshine, but there is a rich and satisfying peace about the place during fruiting autumn that sinks into one's heart too deep for mere words. But then the garden here is a long and well-tended growth of many years. There have been no sudden spurts, no fussy alterations or so-called improvements: there are even some parts allowed to remain, and now planted, for the sake of the memoried past rather than for their present-day use or beauty; and so we have here a garden rich in thought, rich in care, rich in subtle memories, as well as one merely sweet and fair with flowers. The privilege of seeing and enjoying its shady walks and flowery paths is freely granted to all who ask permission to see its many phases, and so it remains to us as one of the most interesting spots in the fertile and historical county of Kildare, which was beautiful and flowery (as history tells us) in the sixth century or earlier, when St. Brigida had her oratory under an Oak tree there, just as the monks in Yorkshire lived under the spreading Yew trees before the walls and roofs of Fountains Abbey arose around them.

F. W. BURBIDGE.

## SOCIETIES AND EXHIBITIONS.

### NATIONAL CHRYSANTHEMUM SOCIETY.

THERE was a large and important meeting of the floral committee of this society on Wednesday, October 23, at the Royal Aquarium, Westminster, Mr. T. Bevan presiding. The display of novelties was remarkably interesting, and some very fine varieties were submitted to the committee. Many of the flowers, however, were only conspicuous by their size, coarseness prevailing to a large extent, uncertainty in tone of colour being also noticeable in many instances. The committee, however, although the task was a heavy one, may be congratulated on having sorted out the grain from the chaff. The principal exhibitors on this occasion were Messrs. H. Cannell and Sons, Monsieur Ernest Calvat, Mr. Briscoe-Ironside, Mr. H. J. Jones, Mr. William Seward, Mr. J. H. Weeks, Mr. W. Wells, Mr. R. Owen, Mr. Godfrey, &c.

First-class certificates were awarded to the under-mentioned varieties:—

**CHRYSANTHEMUM EDITH TABOR.**—A very fine Japanese of large size, having long drooping florets, curly at the tips; colour a very clear canary-yellow, with a faint shading of lemon. Exhibited by Mr. Notcutt.

**CHRYSANTHEMUM MRS. CHAS. BLICK.**—A Japanese of great size and substance, with narrow grooved florets, curling at the tips. This is a pure white variety, and was staged by Mr. C. Blick.

**CHRYSANTHEMUM JOHN SEWARD.**—An English seedling Japanese with great length of floret, a large, substantial flower. The florets are rather broad and of medium width. Colour a fine shade of deep canary-yellow, shaded lemon-yellow. Shown by Mr. Wm. Seward.

**CHRYSANTHEMUM DOROTHY SEWARD.**—Another Japanese from the same source as the preceding, deep rich crimson, tinted carmine, reverse rich gold. From Mr. W. Seward.

**CHRYSANTHEMUM MRS. J. SHRIMPTON.**—A large Japanese variety, having very long florets, twisted at the tips, and of a deep orange-yellow shade, streaked reddish crimson. Also from Mr. Seward.

**CHRYSANTHEMUM LADY BYRON.**—A cross between Mrs. Alpheus Hardy and Puritan. A big incurved Japanese with broad grooved florets. This is a handsome solid-looking flower and was sent by Mr. J. H. Weeks.

**CHRYSANTHEMUM PICCINO (POMPON).**—A globular, well-formed little flower; colour rosy purple, reverse silvery. Raised and exhibited by Mr. H. Briscoe-Ironside.

**CHRYSANTHEMUM MISS ANNIE HOLDEN.**—A neat-looking single variety, a yellow Mary Anderson. One of Messrs. H. Cannell and Sons' novelties.

**CHRYSANTHEMUM MUTUAL FRIEND.**—Another monster white Japanese with a delicate wax-like shade. It has very long curly florets, deeply grooved and a show flower in every way. From Mr. E. Beckett.

**CHRYSANTHEMUM D. B. CRANE.**—An incurved of the old type, solid and substantial in build and with petals of good form; colour deep golden amber. Staged by Mr. H. J. Jones.

**CHRYSANTHEMUM ETHEL ADDISON.**—A massive-looking incurved Japanese, with very broad florets; inside colour rich rosy amaranth, reverse silvery. Also from Mr. Jones.

**CHRYSANTHEMUM DOROTHY GIBSON.**—This is somewhat of a novelty, for it belongs to the reflexed section. It has regularly arranged flat florets, is above the usual size, and the colour is a rich deep golden yellow. Mr. R. Owen was the exhibitor.

Some other meritorious varieties were staged and mention may be made of the following: M. Benj. Giroud, a fine globular crimson Japanese; M. G. Montigny, a large Japanese, white, slightly tinted purple; M. Aug. Gaché, Japanese, white, suffused purple; Mme. A. de Galbert, large white Japanese with broad florets; Mrs. James Lewis, a very fine creamy white Japanese; M. George Biron, crimson and gold; Beauty of Teignmouth, Pride of Madford, an Australian novelty, S. B. Levick, Yelow Source d'Or. T. B. Haywood, &c.

#### THE UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.

THE ninth anniversary dinner of this society was held, under the presidency of Mr. James H. Veitch, on Thursday, October 17, at the Cannon Street Hotel, E.C., when there was present a large number of friends and supporters, more, in fact, than for some years past. The success of the evening's meeting cannot but be ensured both by the lucid and in every other respect admirable address of the chairman, and by the great interest evinced throughout by these gentlemen who supported him. These included Messrs. A. Moss, H. J. Veitch, W. Nutting, P. Barr, G. Wythes, H. B. May, W. Y. Baker, H. Cuthush, H. Cannell, W. Icceton, and several others. In proposing the future and extended prosperity of the society Mr. James Veitch put before the meeting the chief features of this the best of all benefit societies for gardeners to join. He said:—

I do not purpose to-night to weary you with figures, or to enter fully into the benefits to which members of this society are entitled, as probably most of you are better acquainted with them than I am; but there are one or two points I would like to mention. First, and most important of these, is the welcome news that the committee have very recently found themselves in a position to raise the weekly allowance in case of sickness; thus those who contribute on the lower scale will in future, should need arise, receive weekly 12s. instead of 10s. 6d., and those on the higher scale 18s. instead of 16s. That the funds are sufficiently strong to permit of the weekly allowance in case of sickness being raised without raising the subscription there is no doubt—never has the society's condition been so satisfactory as at the present time—the invested funds in trustees' stocks now standing at £10,300 (though I am told their market value to-day is close on £11,000), showing an increase of £600 on the last balance-sheet. For the past three years the investments have increased at the rate of £1000 per annum. The cause of the funds permitting—as they undoubtedly do—of this great move is to a large extent due to the few cases of illness the healthiest of all callings provides, and to the fact that the majority of members are in permanent work, and do not come on the sick fund when ill for only a few days.

On the necessity for thrift in general, and the strong advisability of joining such a benefit and provident society as this when young, it would be easy to dwell, and much might be said on the necessity of thrift for the young men and fore-men in the large gardens of this country, more especially as the occupation they have

chosen has suffered so much, and is still suffering through recent years of depression and through the very large number who are continually entering its ranks. To such would I especially recommend the Benefit and Provident Society. The younger one joins, the sooner a large deposit is acquired, and the sooner one will find himself in the position of certain members at present, whose interest on their deposit is greater than the amount annually paid in subscriptions. Of its security and successful future they may feel assured; and even now, despite an average loss per annum of thirty members—due to death and to some who allow their payments to lapse—the new members average sixty, a nett gain of thirty new members per annum. Not sufficiently well known perhaps is one very important rule, viz., that, by which a member on attaining the age of seventy, when he ceases to participate in the benefits of the sick fund, may annually draw a portion of his balance (which at that age must necessarily be large), and at the same time be qualified for assistance from the benevolent fund, should he require it. It is true no member has as yet availed himself of this rule, the reason probably being the society has only just existed long enough for it to be possible.

Peculiar to this society, and undoubtedly of great value, is the convalescent fund, a fund which owes its existence to the foresight and generosity of Mr. Sherwood. This fund is purely a voluntary one, and it is at the disposal of the committee to send away for a time any member who may have been so prostrated by illness as to render a change imperative, but who may not have the wherewithal needful. To generous friends, and to those who are enjoying a larger share of the good things of this world than falls to all of us, I would venture to ask something more than a kindly thought for this fund when the United Horticultural Benefit and Provident Society next comes uppermost in their minds.

Most of us here, and certainly those interested in the three great bodies for doing good connected with our calling, are aware of the use this society must be to any member in case of illness, but to our visitors I would say, for a moderate monthly payment he receives a liberal weekly allowance during sickness; for no payment at all he may, if a fit subject in the opinion of the committee, participate in the convalescent fund. Should he in his old age be in want, the benevolent fund is at his service; and last, but not least, for in this point the society differs from others of its kind, he does not lose his deposit should his payments unfortunately lapse, and he, at the age of seventy, or in case of death any one he may have named, may withdraw the full sum with the interest placed to his credit up to the time he ceased subscribing, without any deductions whatsoever.

In a few words spoken later in the evening by the treasurer (Mr. James Hudson), allusion was made to the splendid progress made by the society since the inauguration of these anniversaries in 1887. Then when the society had attained its twenty-first year there were 177 members (benefit) on its books, now there are 581. Then the invested funds amounted to £3650, whilst now they stand at £10,300. There were in 1887 12 hon. members, now there are 50, this showing beyond any doubt the soundness of the society, than which no better argument in conjunction with the thoroughly practical speech of the chairman could be deduced. The surprising fact remains that gardeners do not join its ranks in still greater numbers, but there is one most pleasing feature—it is that of gardeners joining from all parts of the United Kingdom, thus showing that the society has their confidence. Mr. Sherwood again contributed £5 5s. to the convalescent fund, Messrs. Icceton and Mott both became life members of £10 10s. each, and Messrs. Arthur W. Sutton, Geo. Wythes, and H. J. Jones hon. members of 21s. each annually, whilst donations came from Mr. A. F. Barron and Mr. Geo. Monro, each of 21s. There was a most liberal display of flowers and plants from Messrs. Veitch and Sons, B. S. Williams and Son, H. Cannell and Sons, Laing and Sons, and others, a plentiful dessert adding to the features of the tables. The chairman announced that for the chairman of of next year he had secured the services of Mr. W. J. Nutting, of Messrs. Nutting and Sons, whose wide experience will stand him in good stead for that post.

Those desirous of obtaining rules, &c., can have the same forwarded on application to the secre-

tary, Mr. W. Collins, 9, Martindale Road, Balham, S.W.

**Royal Horticultural Society.**—The next fruit and floral meeting of the Royal Horticultural Society will be held on Tuesday, October 29, in the Drill Hall, James Street, Victoria Street, Westminster. The committees will meet as usual at 12 o'clock, and at 3 p.m. a magic lantern lecture on Potatoes will be delivered by Mr. A. W. Sutton.

#### NOTES OF THE WEEK.

**The mildness of the season.**—As showing the extraordinary mildness of the season, says the *Western Morning News* of October 21, a large dish of beautifully fine and ripe Strawberries was on Thursday last gathered by Miss Gladys Wade in the gardens at Wear Gifford Rectory, near Bideford.

**Michaelmas Daisies in pots** make pretty groups in the greenhouse at Kew, and doubtless there are many who might grow and enjoy them in this way. It is important to select suitable kinds. Those of slender and free-branched growth are most suitable, the varieties of *A. cordifolius* such as *elegans* and *e. Diana*, also *A. turbinellus*, being the best at Kew. *A. ericoides*, too, a most graceful and late-flowering sort, would well repay any extra attention of this kind, and last long in flower in a cool greenhouse.

**Apple Bismarck.**—This Apple has borne a heavy crop of large, handsome fruits on young trees this season, and bids fair to become a profitable variety. The trees themselves are exceedingly healthy and show no signs of canker. Some English Paradise stocks were grafted with Bismarck last April, and one, which produced three shoots of about 18 inches in length, was found to be carrying three fruits, the largest of which scaled 9 oz., while the remaining two weighed between them a trifle under 10 oz.—S. W. F.

**Adiantum Farleyense.**—This when well grown is perhaps the finest of all the Maiden-hair Ferns, its heavy, luxuriant fronds being none the less graceful although so massive. In a warm house at Howick we lately saw two grand specimens growing in baskets suspended from the roof. The largest plant was a magnificent piece. The basket it filled was of considerable size, and the diameter of the plant, if the drooping fronds were held up horizontally, would not be less than 6 feet.

**Flowers from Winchmore Hill.**—Mr. Perry sends us a gathering of good things still in flower with him. *Chrysanthemum latifolium grandiflorum* is a very fine form, but *Coreopsis pubescens* is not unlike a fine variety of *C. lanceolata* we have had. *Inula ensifolia* is a dwarf in a family of giants, only about 5 inches high, but making tufts of yellow bloom. Some good varieties of double Primroses we note with pleasure, also the purple Groundsel, a good late autumn flower, and fine Asters. W. Bowman still remains the best form of the purple New England Aster, and *A. Bigelowii* as sent is very good.

**Tropæolum pentaphyllum.**—A trio of graceful climbers that we like to see often are *Tropæolum speciosum*, *T. tuberosum* and the species above mentioned, which we noted flowering freely at Elington Hall. It is perhaps the least showy of the three, but none the less charming, quite distinct from either of the others, its long, spurred flowers with their reflexed segments resembling those of some of the Fuchsias of the *F. reflexa* type. These plants are such light and slender growers, that even our choicest shrubs may furnish them the needful support and gain much in beauty by doing so.

**Smilax aspera** makes a fine screen of rich leafage and a beautiful mantle for the back wall of a glass house. There is a grand plant of it in a house at Chillingham Castle. This was raised

from seed brought home from the Riviera. From the base to the top of the high back wall it forms a mantle of deep green, and the shoots are terminated by long feathery panicles of tiny creamy white flowers. In southern gardens it is quite hardy, and might be seen more frequently, especially scrambling over a bold rock in a rock garden. It has heart-shaped leaves with curved spines along their edges.

**Sunflower Bouquet d'Or.**—This is a beautiful double-flowered variety of *Helianthus multiflorus*, which we noted among many good hardy flowers in the garden at Eslington Hall. It is quite distinct from the variety *Soleil d'Or*, and differs particularly from the ordinary form of *H. multiflorus plenus* in its well-defined outer ray of broad guard petals. The centre is very full and the colour of the entire flower a deep rich yellow. It flowers profusely and the blooms are borne on long stems well above the leaves. Both for effect in the garden and for cutting it deserves a place among the best autumn flowers.

**Heliotropes.**—Among the charming series sent to us for trial by Messrs. Bruant, of Poitiers, are Mme. René André and Madeleine Viand. Perhaps the most charming of all is Mme. René André, a soft deep purple, a distinct and beautiful kind which deserves to be grown in every garden where Heliotropes are cultivated. Mme. Barsby has flowers of a deep violet-blue colour, and Mme. Bruant in a similar rich shade is a superb kind. Cameleon and Picciola are two more handsome kinds of tall, robust growth, quite shrub-like, and covered with large trusses of reddish purple flowers.

**Berberidopsis corallina.**—A very fine plant of this is now in bloom at Craggside, Northumberland. It is grown under the same conditions as the *Desfontainea* noted in THE GARDEN (p. 310), but is stunted to the wall at the back, which it completely hides from top to bottom, whilst it has a branch-spread of rather more than 6 yards. Growing outwards from the wall and drooping gracefully are hundreds of slender shoots, each one terminated in a long raceme of many deep coral-red flowers and buds. Its beauty will last for a long time to come, as doubtless the protecting lights will soon be placed in position.

**Morina longifolia** deserves more attention from those who grow hardy flowers, as we rarely see it in gardens. We noted several handsome tufts of it in the borders at Craggside, where it does well, as some of the finest spikes had borne no less than twelve whorls of flowers. Such spikes last many weeks in flower, produce numberless blossoms, and are quaintly pretty, with the varying tints of the white woolly buds and expanded flowers, which are first blush-white, but develop colour till they become deep rose. The flowers are sweetly scented, and the leaves give off an agreeable scent when handled, but they are too spiny to permit of much handling.

**Berberis chinensis or Thunbergi.**—In the whole group of *Barberis* and *Mahonia* there is no kind so varied and delightful in its several aspects of seasonable beauty as this. It is a deciduous kind, and herein lie its varied charms. Its new leaves in spring are of the lightest shade of tender green, the flowers deep lemon-yellow, whilst it finishes up the season before its leaves fall with a perfect glow of orange and vermilion, quite one of the most beautiful shrubs for autumn colour. We saw a nice bush of it recently at Blagdon, Northumberland, but it is a shrub that should be frequently seen in gardens boldly massed or grouped, not in single isolated bushes.

**The Sweet Verbena at Howick.**—In the flower garden at Howick, Northumberland, several beds are filled with this plant that is always welcome in the garden. It is hardier than generally supposed, as although Howick derives some benefit from its nearness to the coast, 27° of frost were registered here last winter. The plan adopted by Mr. Inglis for the protection of the Sweet Verbena during winter is to thicken mulch the bed with leaves, which are filled in among the

branches of the shrub to keep the leaves in place. The plants are not cut down till the protection is removed in spring. This fragrant plant is worth such attention to preserve and ensure its growth every year.

**Stocks in northern gardens.**—When looking through some of the best northern gardens, even as late as the middle of the present month, we saw fine Stocks in abundant bloom. At Howick a long border in the kitchen garden had a row of the East Lothian purple Stock, a good strain, deep and rich in colour and kept very true. Mr. Inglis saves his own seed, which gives 80 per cent. of perfectly double-flowered plants. A white Intermediate Stock was also very good and profuse in blossom. At Lambton, too, we noticed that Mr. Hunter grows Stocks extensively in the beds and borders, and here also they were flowering freely at the time of our visit.

**Tree Carnations.**—I herewith send you a few blooms of Miss Joliffe and La Neige Carnations. I cannot distinguish the slightest difference between the so-called Miss Joliffe Improved and the original stock. I do not disbud, as if terminal blooms are not wanted, the secondary ones come in later on. Were disbudding practised, the individual blooms would doubtless be larger.—J. CRAWFORD, *Coddington Hall, Newark.*

\* \* A very beautiful gathering, the flowers of La Neige of the purest white and sweetly scented. As sent, we cannot see the slightest difference between Miss Joliffe and its so-called improved form.—ED.

**Flowers from Orleans.**—Messrs. Barbier Brothers, Orleans, send us an interesting addition to the beautiful things of the present week in a variety of Polygonum, *P. amplexicaule*, that has long sprays of pure white blossoms. It is a pretty Knotweed and deserves to be grown with the best of the family, which is so valuable and good in colour, and so free even in places outside the garden proper. They also send *Helenium autumnale superbum*, which no doubt is a good autumn plant. The flowering qualities of these *Heleniums* are splendid, although we doubt if any of them show this fine quality in such a high degree as the little *H. pumilum*, which with us begins in summer and flowers right on.

**Carnation Reginald Godfrey in autumn.**—As promised, I herewith send you a few blooms of Carnations. To really appreciate these varieties you want to see them growing. I grow all the popular kinds, but of my strain I get a plant in two-thirds of the time and with five times the quantity of bloom. The pink is Reginald Godfrey; the nearest variety to it is Mrs. Leopold Rothschild (syn., Mlle. Thérèse Franco), but the latter is a much slower grower, gives but one-fifth of the flowers, which are more apt to burst and not so sweet-scented. I struck plants of Reginald Godfrey in March, planted them out in May, and had sheaves of good bloom in August. I took the plants up about six weeks ago and they are now coming into bloom again and will go right through the winter. The white is Miss Mary Godfrey.—W. J. GODFREY, *Exmouth.*

**Autumn Snowdrops.**—The first Snowdrop of autumn here is the *Galanthus octobrensis*, which opened its flowers on October 3, but it was very quickly succeeded by a couple of bulbs of the rare *G. Reginae Olga*, which I owe to the generosity of Herr Max Leichtlin, of Baden-Baden, who has succeeded in again introducing it to our gardens. The last-named kind, like *G. octobrensis*, blooms on scapes 5 inches to 6 inches in height, that appear before the leaves. It has an elegant, drooping, long-petalled flower, and the markings on the inner segments are large and of a peculiar pale soft green tint. This variety was grown by the late Rev. Harpur-Crewe, but seems to have been lost after his death, so that we are all the more glad to welcome it back to the ranks of cultivated autumnal-flowering Snowdrops.—F. W. B.

**Fruit farming.**—Mr. George Barham, Danehurst, Hampstead, in a letter to the *Morning Post* concerning the carriage of fruit, says: "Why

do not farmers grow more fruit?' is a question often asked by our urban friends. Perhaps the following little incident may enlighten them, and at the same time be worth the notice of our new Minister of Agriculture, for unless something is done by those in authority to protect individual farmers from such cases of imposition, fruit must be left to rot on the ground and land continue to go out of cultivation. I have a small orchard at one of my Sussex farms, and seeing that I could only get 6d. a bushel offered for the Apples, which are of good quality, I ordered the bailiff to send a few bushels to my house in London. Four bushels have arrived, and the railway carriage paid to the carman on delivery was 6s., or just three times the value of the Apples. The sending station (Wadhurst) is forty miles from London, and the South-Eastern is the railway company which thus strangles and destroys the trade and agriculture of the district."

**Laurustinus at Howth Junction.**—For many years I have admired the clean, dense and healthy aspect of this shrub as grown on the exposed platform of the G.N.R. station at Howth Junction, whence the line diverges for Drogheda and Belfast. This year the flowers are earlier than usual and also much more profuse and beautiful; indeed, they remind one of the old exhibition plants of the past, the "elephants" of the Baines, Cole and Cypher epoch, since these *Laurustinus* bushes remind one of nothing so much as gigantic *Ixora* bushes covered with snow-white trusses of bloom instead of with scarlet ones. Howth Junction stands on a wind-swept neck of land with sea on both sides and is fully exposed to the N.W. gales, and yet *Laurustinus* and Portugal Laurels grow most luxuriantly and flower well also on the warm sandy soil. The only shelter is a slight belt of Larch or Pine on the windy side. Those interested in sea side flowering shrubs might do worse than include all the forms of the *Laurustinus* amongst their selection when planting.—F. W. B.

**Outside Tomatoes in October.**—To see Tomatoes ripening their fruits on open walls in October is a rare occurrence at any time in this country, the more so when the middle of the month is a thing of the past. Yet notwithstanding such is the fact, the foliage and growth very little worse than we see often in summer. I was quite surprised to see the above during a quiet walk the other day. The Tomatoes were growing against a brick wall about 6 feet high, and the plants which had been fruiting for some time were well to the top of the wall, carrying good trusses of large shapely fruits. No protection has been given them at any time; indeed, any such has scarcely been needed, while the full south aspect has evidently just suited the later set bunches of fruit. The exceptional heat of September as well as the comparative absence of rain, and, not least, the warm nights of which we have had a full share, have no doubt all played a part in the full and complete ripening of such good fruits in the middle of October.—E. J.

**Cosmos sulphureus.**—Referring to recent notes in THE GARDEN on *Cosmos sulphureus*, if Mr. W. Thompson will examine his plants more closely he will perhaps discover that they are *Bidens ferulefolia*, not *Cosmos sulphureus*. At least, this has been my experience with seeds said to be of *C. sulphureus* from New Zealand, evidently from the same source as those secured by Mr. Thompson, and to which his description fits. *C. sulphureus* (Car.) is in cultivation here, though rare, and a first-rate annual. Under cultivation it forms a sturdy, much-branched plant, 4 feet to 5 feet high. It flowers in a young state and through the season. The flowers have the blunt wide petals of *C. bipinnatus* and are equally large. They vary somewhat in colour, from light to deep orange-yellow. *Cosmos* vars. are favourite plants here, but mostly flower too late in the season to ensure a safe crop of bloom out of doors in this latitude. Some selections of *C. bipinnatus* have been made lately which flower earlier than the type and which will prove valu-

able. The yellow species noted above is also likely to be much appreciated for its early-flowering habit as well as its fine colour.—J. N. GERARD, *Elizabeth, N.J.*

**Schizostylis coccinea.**—Clumps of the above dotted about the herbaceous borders are now expanding their beautiful crimson flowers, which should severe frost keep off promise to be finer than usual this year. No more useful or easily grown plant than this can be found for conservatory decoration during the early winter months. Plants intended for this purpose are best prepared by breaking up the clumps into small pieces in April and planting them 15 inches apart in good soil upon a south border. An occasional watering until they are established and keeping free from weeds is all the attention they require throughout the summer. The plants should be lifted and potted early in October, or before sharp frosts are likely to occur, as I have found that plants grown in rich soil are more susceptible to injury from frost than are those that have stood for some years in the same place. Last year ours were not lifted on October 19, when a sharp frost occurred, which sadly crippled the flowers, many of which failed to open. Others scattered about the border and under the shelter of fruit trees escaped and gave a quantity of spikes of bloom until the new year.—JAMES DAY, *Galloway House, Gartliestown, N.B.*

**Railway station flower gardens.**—It is to be hoped that other railway companies will imitate, or even emulate, the action of the Midland directors, and institute prizes or other inducements for the making and keeping of useful and pretty gardens along their lines. After all it would be an economic policy, for in no other decorative way would a few pounds go so far and afford so much satisfaction to the railway officials themselves, as well as to the travelling public. Let us hope that the dreary and bare country stations will soon be a memory of the past, and that the careful planting of well-selected trees, shrubs and flowers may become the rule. Self-interest alone has often prompted porters and signalmen to till the waste land around their stations, and often with the most beneficial results to all concerned; but it still remains for the directors to offer more facilities.—F. W. BURBIDGE

—The North-Eastern Railway Company also give prizes for the best floral display at stations on their lines, and we were pleased to see good culture of flowers in a very wild and wind-swept part of Northumberland along the branch line from Alnwick to Cornhill. This line has not been made many years, and the station buildings are particularly well adapted for growing flowers. Certainly flowers were never more welcome to us than here, some of the stations being perfect beauty spots set in a desolation of rock. The passenger shelters upon the platforms are not only roofed with glass, but have glass fronts as well—are in fact perfect conservatories if suitably adorned. The best station we saw along this branch was that at Wooperton, and although time did not permit of our alighting to examine it closely, we noted during the short stoppage of the train excellent tuberous Begonias, Fuchsias, Petunias, zonal Geraniums and fine pots of Lobelia flowering under glass, and a pretty compact flower garden had been made. In this, too, Begonias and Geraniums were prominent, as also was a broad and beautiful edging of the small-flowered *Tugetes*, gay with myriads of flowers.

**The weather in West Herts.**—A cold week, the temperature in shade on no day or night reaching the average. On the 22nd the highest temperature in shade was only 43°, while during the night preceding the 8th the exposed thermometer showed 7° of frost. Very nearly all the flowers of both Cactus and single Dahlias were destroyed by this frost, also most of the upper shoots. At 2 feet deep the temperature of the soil has now fallen to 51°, and at 1 foot deep to 47°, the latter reading being 3° below the October

average. Rain fell on but two days, and to the total depth of less than half-an-inch. Throughout the 19th and 20th the air remained unusually calm, the average rate of movement being only about a mile an hour. During the last five days less than an hour's sunshine has been recorded.—E. M., *Berkhamsted.*

## OBITUARY.

MR. C. F. BAUSE.

THROUGH the death of Mr. C. F. Bause, which we much regret to announce as having taken place at the Moreland Nurseries, South Norwood, on the morning of Wednesday, the 23rd inst., after a long and very painful illness, horticulture is deprived of one of its most fervent and most active members. As a grower of plants in general Mr. Bause had few equals, while in the cultivation of stove plants in particular he occupied a most prominent position. It is, however, as a raiser of new plants that Mr. Bause's name is best known and most deservedly popular, for his success in raising new varieties of fine-foliaged plants is unequalled in this or any other country. Although of German extraction, Mr. Bause spent the best part of his life in England, where he came in 1863 and made his *début* with Mr. Herbst at Richmond, where he remained eighteen months. He then entered the service of the Royal Horticultural Society's gardens at Chiswick, where as a propagator and grower he, being a keen observer and exceptionally good and quick worker, soon attracted the attention of his superiors. In 1866 the horticultural world was startled by his production of new Coleuses, six of which were sold at Stevens's under the hammer for £250, and purchased by Messrs. Veitch. These were the forerunners of all the magnificent forms with which our parks in summer and our greenhouses in winter are now adorned. A little later on he succeeded in raising a race of Caladiums, which were distinct from those raised by Mons. Bleu, of Paris, inasmuch as the ground colour of most of the varieties was a bright yellow, on which the red markings formed a most pleasing contrast. Notwithstanding the many forms in commerce, such varieties as Prince of Wales, Princess of Wales, Princess Beatrice, Princess Teck, and the charming and highly coloured Fred. Bause are still some of the most distinct forms found in collections now-a-days. This was followed by the raising of several hybrid Dieffenbachias, the most distinct among them being D. Bausei.

Mr. Bause's abilities as a plant grower were appreciated by the late Mr. J. Veitch, and in 1869 he entered the Royal Exotic Nurseries, Chelsea, as a Fern grower, which department he left in 1871 to take charge of the new plant department, which was then very important, as that was the date of so many introductions of beautiful leaved Crotons, Dracenas, Anthuriums, &c. While he occupied that position he also raised several good and distinct forms of Poinsettias, from the intercrossing of the forms with white and scarlet bracts. In December, 1873, the deceased left the Chelsea Nurseries to take charge of Mr. Wills' establishment at Anerley, where he soon distinguished himself by the raising of many new and most beautiful forms of Dracenas, many of which have held their ground against all comers to this day. Many of our readers will remember the extraordinary fine show made by the late Mr. Wills during the Paris Exhibition in 1878 with plants either raised or grown by Mr. Bause. It was during his management of the Anerley Nurseries that the deceased raised the very distinct *Adiantum Bausei*; whereas *A. rhodophyllum*, *A. deflexum*, *Nephrolepis Bausei*, and *Pteris Bausei* were raised by him soon after he in 1884 started on his own account at the Moreland Nurseries, South Norwood. Two years ago he raised a new race of Caladiums, the stock of which was secured by Messrs. Veitch, who are now sending out such as Chelsea Gem, Duke and Duchess of York, &c.,

all beautiful and very distinct in colour and habit.

Mr. Bause, to whom all persons interested in fine-foliaged plants are more or less indebted, was of a very sympathetic nature, and made friends of all who came into contact with him. He leaves to mourn his loss a devoted wife, two daughters, and three sons, one of whom is now managing the business which he created and organised.

**Death of Mr. Crispin.**—All his gardening friends will have heard with regret of the death of this gentleman, after a long and most painful illness, at the comparatively early age of 55 years. For many years Mr. Crispin has been well known and respected throughout the west of England, where his unfailing good nature has made him a host of friends, and the great progress he made in business testifies to his capabilities in this respect. He was an ardent gardener, and his leisure hours were spent among his Orchids, Roses and other beautiful plants which he grew so well. Mr. Crispin was beloved by all who knew him, and by those who came into close contact with him and knew his genuine kindness of heart he will long be remembered.—H. R.

**National testimonial to Mr. A. F. Barron.**—The retirement of Mr. A. F. Barron from the important position of superintendent of the Royal Horticultural Society's gardens and exhibitions is regarded as a fitting occasion for presenting him with a testimonial. Known personally to a large number, and to a wider circle by reputation, his public work as superintendent of the time-honoured Chiswick Gardens is valued by all who have had the opportunity of judging. His management of the gardens for the long period of thirty-five years, and the success with which he has carried out various important trials and experiments in plant and fruit culture, have inspired confidence on every hand. His treatises on the Vine and the Apple are standard works of reference; his integrity and loyalty to the trust reposed in him, his amiability of disposition and readiness at all times to impart information have endeared him to the horticultural world generally; whilst his capacities for organising and carrying out to a successful issue numerous great exhibitions have secured for him general admiration. As the honorary secretary of the Royal Gardeners' Orphan Fund from its beginning in 1887, he has largely contributed to the success of that valuable institution. The committee therefore confidently appeal for subscriptions towards a fund for presenting Mr. Barron with some tangible mark of gratitude and esteem. In so doing the committee earnestly desire that all gardeners and lovers of their gardens shall have an opportunity, according to their means, of participating in a suitable acknowledgment of the life-long public services of one of the most worthy and eminent of British gardeners. The secretaries are Mr. W. Marshall, Auchinraith, Bexley, and Mr. B. Wynne, 1 Danes Inn, Strand, W.C.

**Names of plants.**—*T. E. W.*—A form of the common Ash with undivided leaves (*Fraxinus excelsior* monophylla).—*S. T. Spear.*—*Hydrangea hortensis.*—*Ellen E. Stevenson.*—*Linaria purpurascens.*—*E. Dasherwood.*—*Campanula turbinata.*

**Names of fruit.**—*Mrs. G. C. Greenell.*—1, Williams' Bon Chrétien; 2, Worcester Pearmain; 3, not recognised; 4, Emperor Alexander; 5, King of the Pippins; 6, Golden Spice.—*John Bram.*—1, Comte de Lamy; 2, rotten; 3 and 4, Flemish Beauty.—*Chas. Carter.*—Apple, Crofton Scarlet.—*R. Henderson.*—1, Gravens'ain; 2, Yorkshire Greening. *W. P. N.*—1, Pear Duchesse d'Angoulême; 2, Fondante d'Automne; 3, Baurré Superfin; 4, Marie Louise; 5, Baurré Diel; 6, Nouvelle Fulvie; 7, Catillae; 8 and 9, not recognised; 10, Forge. It would greatly assist us if those who send fruit for naming would state the district from whence they write. *A. F. E.*—Pears, 1 and 9, Baurré Diel; 2 and 3, Brown Baurré; 4, not recognised; 5, Louise Bonne de Jersey; 6, Knight's Monarch; 7, Leon Leclerc de Laval; Marie Louise; 10, Souvenir du Congrès. 11, Doyenné Boussoch.

No. 1250. SATURDAY November 2, 1895. V. I. XLVIII.

"This is an Art  
Which does mend Nature; change it rather; but  
THE ART ITSELF IS NATURE."—*Shakespeare.*

## ORCHARD AND FRUIT GARDEN.

## FLAVOUR IN PEARS.

THERE has been an extraordinary difference in the flavour of Pears this year, in some cases it being wretched, while in others it has been excellent. Pitmaston Duchess is the most remarkable instance on our light soil, and I think this proves that a hot season is requisite to get this showy Pear in its best condition. In ordinary years its size and appearance are its chief recommendations, the quality being decidedly second-rate, but this year it is delicious. Another fine looking variety is Beurré Clairegeau. As a rule the flavour is only third-rate; this season it is very good and far superior to any I have ever tasted previously. General Todtleben is very large, but usually only fit for stewing; the few fruits that have already ripened are nearly first-rate in flavour. Marie Louise is not so good as usual; the fruit is equally large and as well grown as in former years, but the flavour is most decidedly below the average. Later fruit from bush trees may possibly possess the full and exquisite flavour so much esteemed in this variety. Brockworth Park has been the most insipid Pear I have tasted this year; the fruits contained plenty of juice, with less flavour than is present in a Turnip. Thompson's is also disappointing this season. The crop and size of fruit have been all that could be desired; not so the flavour, as that peculiar and pleasant taste characteristic of this variety is almost entirely absent. Durondeau is splendid in quality, in fact it may be termed exquisite, and up to date (Oct. 21) is the best flavoured Pear I have tasted. This variety is worth planting more freely, as it is a hardy and prolific sort, of handsome appearance and rich quality in all seasons. Beurré Hardy is another sterling variety; the trees nearly always bear well, the fruit is large and attractive and of very good flavour. This year it is extra rich and melting, and in my estimation is one of the most reliable varieties, especially in bush or pyramid form. Beurré Superfin has been very fine and ran Durondeau very closely in flavour. This excellent variety is generally grown against a wall, but in favourable Pear-growing districts it succeeds admirably in bush form, cropping freely, and affording a succession to the fruit from wall trees. Clapp's Favourite was of extraordinary dimensions this year, with a lovely colour on the sunny side, but the flavour was of the usual indifferent character, and a long way behind that of Souvenir du Congrès, which ripened at the same time. The latter variety surpasses its parent, Williams' Bon Chrétien, on our soil, as it crops more heavily and is of better flavour. Beurré Diel is specially fine this year on wall trees and the fruit of rich flavour; on bush trees it has not been quite so satisfactory. Beurré d'Amanlis has been decidedly poor in all respects this season, much of the fruit being infested with dark spots on the skin, and a large proportion decayed in the centre while hanging on the trees. Comte de Lawy is always excellent, this season being no exception to the rule. This variety is not so much grown as its merits warrant. No doubt its small size is an objection with many, but for the table it is large enough, and if pruned on the extension system is a very prolific sort.

Fondante d'Automne is another delicious Pear, rarely failing to crop well; this year the fruit has been very attractive and rich in flavour. Marie Louise d'Uccle is never of first-rate flavour with me, but this year it is worse than ever; still it is a good market variety, as the fruit is freely produced, of good size, and nice shape. Magnate promises to be in demand in the future, as the fruit is large, beautiful in appearance, and of a rich and pleasant flavour. The quantity and quality of the produce from small bush trees have pleased me this year, and I should think this variety will prove valuable for market growers. Suffolk Thorn is now in use; the medium-sized fruits are distinct and rich in quality and scarcely influenced by seasons, both cordon and bush trees usually bearing moderate to heavy crops. Flemish Beauty is very poor in flavour this year, and the same applies to Doyenné Boussoch, neither being so good as last year. For a number of years I have made notes on the flavour of Pears, and it is most interesting to observe how they vary with the seasons, showing how greatly they are influenced thereby. W. G. C.

**Pear Uvedale's St. Germain.**—This stewing Pear is not considered suitable by some growers to grow as a bush tree, as they contend that it is a shy bearer in that form. With me it is most prolific as a bush, quite young trees producing excellent crops of large fruit. One tree planted three years ago had 46½ lbs. of fine large Pears picked from it last week. As a standard it succeeds splendidly on deep, fertile soil. At Rotherwas, near Hereford, Mr. McCabe pointed out a big tree loaded with immense fruits, this gardener further stating it had carried similar crops for many years.—R. H.

**Apple Emperor Alexander.**—At a recent fruit show this variety was staged in a collection containing a sort named Grand Duke Constantine, the exhibitor no doubt believing the two varieties named to be distinct. After growing them side by side I cannot detect the least difference in growth, foliage, or fruit, and I believe them to be identical. Looking through a fruit catalogue received a few days ago, I noticed that Emperor Alexander had Constantine bracketed with it. Many interested people visit our leading fruit shows to take notes of the names of fruit that may to them appear the best, and many of them are not sufficiently expert to see that imposing dishes are exhibited under two or more names. Then trees are ordered, and in a few years they find they have the same Apple under different names, and naturally are somewhat annoyed.—W.

**Apple Egremont Russet.**—Very few of the Russets will equal this variety for general excellence both on the English Paradise and free stocks. It comes into bearing rapidly and produces moderate crops of fruit, fit for dessert at any time from the end of October to the end of March. The habit of growth is specially suitable for small gardens, as it forms an upright, close growing tree, that requires some of the weaker and inner shoots to be removed entirely to allow the wood ample light to perfect the fruit buds so freely formed.—R. H.

**Peaches outdoors.**—I am pleased to see some of our younger gardeners commenting on the culture of Peaches, Nectarines, and Apricots on open walls, and am very pleased to hear some of them succeed. I commenced the care of trees on open walls in the autumn of 1837, and had a fair experience of the cold in January, 1838. I started in the gardens of Beckett Park and Coleshill, Berks, where good fruit was grown on the open walls in those days. In fine seasons we used to get good crops of Figs on the walls, there being very little glass. Thirty years ago the great rage for summer bedding started, and of course the flower garden had to be kept nice whatever else was neglected. This was quite fatal to growing fruit on open walls, as frequently there was

no extra assistance to get through a great amount of extra work, and the consequence was Peach and other trees were not disbudded at the proper time, and they were left to be cleansed by the summer showers instead of the garden engine. The gross growth was allowed to overcrowd the proper bearing wood, and the nailing or tying was left much too late. Since leaving Berks I have lived in Devon, Kent, Surrey, and the neighbourhood of London, but never found any difficulty in getting good crops of stone fruit when I had drained the borders and given the trees good loam with a little lime rubbish to grow in. Prune and nail, disbud in proper time, keep clean, and water when necessary, and you will be well repaid.—R. BUTLER.

**Apple Ribston Pippin.**—The best of all possible answers to those who assert that the Ribston Pippin is dying out was the grand exhibit at the recent Crystal Palace show, where over one hundred dishes of this fine Apple were shown in splendid form, probably the finest lot ever brought together. Amongst the whole of the dishes not an inferior fruit was shown, and the first prize lot was a revelation to many growers. The hot summer is probably responsible for the extra quality, and has evidently suited the Ribston better than a cooler and less sunny season would do. I find this Apple at least as constant in bearing as most other varieties, and more saleable than any other, with the exception of Cox's Orange Pippin. The importance of allowing free growth, as pointed out by "S. H. B." (p. 274), must not be forgotten by those who wish to make sure of an annual crop of Ribston. Thinly branched bush trees with lateral growth left intact or only very lightly thinned may be expected to fruit freely and to carry fruits that will keep later in good condition than those grown on severely restricted trees.—J. C. TALLACK.

**Outdoor Grapes in Surrey.**—At Downside, Leatherhead, are to be seen really excellent crops of both black and white (Grapes against a low wall with a southern aspect. The wall is but a yard high—in fact, it is the wall supporting the front of the conservatory. The black variety, Mr. Mease thinks, is Black Cluster, the white, Foster's Seedling. Bunches of the latter weigh fully three pounds each and the berries are very good. The black variety has capitally finished berries. The same treatment as is accorded to indoor Vines as regards the manipulation of the shoots is practised, close spur pruning being the rule, and with excellent results too.—E. M.

## FRUIT ROOMS.

FRUIT rooms are often built in any convenient spot regardless as to whether the position is a suitable one, and their general character is frequently quite the opposite of what is required for keeping Apples and Pears over the longest possible period. In the first place, fruit rooms should never have a south aspect, nor yet be lofty. The reason for this is apparent. When facing the sun, that agent, especially during October and November, runs up the temperature to far too great a degree, the fruit ripens speedily, and is soon past and gone. Lofty structures become too dry and arid, and thus also hasten premature ripening and speedy decay. The best fruit room I know of is constructed behind a high bank of earth and facing due north. It is entered by descending several steps, and is covered by a heavy thatched roof, ample ventilation being provided. In the south of England I have known many varieties both of Apples and Pears to keep sound and good for several weeks after they had disappeared from ill-constructed fruit rooms in midland and northern districts, and this in spite of the fact that the southern fruit ripened a fortnight sooner. A cool even temperature is what is wanted to preserve fruit, and to enable late sorts of Apples to retain their weight. So long as actual freezing does not occur the fruit will take no harm in winter, and it is far better to cover

slightly with a little dry fern or hay in extra sharp weather than to apply fire heat. At the same time every fruit room should be furnished with a stove for use in such winters as that of 1894. I do not approve of the old way of laying the fruit upon cushions of hay or similar moisture-retaining material. I prefer to lay sheets of coarse brown paper over the shelves when storing soft-fleshed, tender-skinned sorts, but firm, thick-skinned, long-keeping Apples do very well simply laid not too thickly on the bare shelves, which ought to be of a latticed character, in order that a current of air may pass through the fruit. When examining the fruit and removing any decayed a candle should be used rather than open the shutters for any length of time, oft-repeated light having a tendency to hasten on the fruit and also to reduce its weight. Where there is plenty of space, the more thinly Apples are stored the better, as it goes without saying that the greater the pressure the greater the liability to rot, and by thin storage faulty fruit is more easily detected, and the labour of sorting reduced. Apples will keep well in cellars, provided they have no windows facing south into which the sun can shine. J. C.

#### MILDEW ON VINES.

I HAVE been very much troubled with mildew in my viney, so much so that I have lost all my Grapes the last two years. Can you advise me how to get rid of it, and what means I had better take to save my crop in the future? I have given the house all the air I could the last two years, but that seems to have had no effect either in stopping it or even mitigating its effects.—THOS. R. WHITE.

\*. \* Once mildew (*Oidium Tuckeri*) is well established in a viney it is very difficult indeed to get rid of it. In some instances the Vines have been so weakened by its repeated attacks, that the best way out of the difficulty has been to completely clear out rods, Vine border, and anything else that is likely to form a resting-place for the spores of this much-to-be-dreaded fungus. In addition to this the glass was cleaned, the woodwork painted, and the walls generally thoroughly coated with hot lime-water—together a drastic, yet most effective remedy. The next best plan, and which if successful, as it most probably will be if carried out in a thorough manner, does not entail the loss of a single crop, is to prune the Vines after they have been duly rested and then commence the work of cleansing. Remove all loose bark from the Vine rods and all rubbish from the house generally, and then well brush into the rods a composition made as follows: Place  $1\frac{1}{2}$  lbs. of flowers of sulphur and 2 oz. of lime in a saucepan, with 6 quarts of water. Boil down to 3 quarts, and then strain through muslin. One wineglassful of this is sufficient to mix with 4 gallons of water, and this ought to be strong enough to destroy mildew without injury to plant life. Scrub the rods thoroughly, well brushing the mixture into all the crevices. A repetition of this treatment a few days later on—in fact, three or four times during the winter—will be found far more effective than dressing with insecticides thickened with clay. Also clean the glass and scrub the woodwork with hot water, in every gallon of which a lump of soda and soft soap about the size of a bantam's egg have been dissolved, following this up with at least one good coat of paint. The mildew composition might be used for cleansing the woodwork of mildew germs, but stains badly. Lime-wash the walls, not making the dressing too thick, or otherwise the crevices will not be reached. If the border is an inside one, carefully fork away and wheel out every particle of surface soil to the extent of well baring the roots, give a soaking of liquid manure if dry and poor, and then top-dress with a fairly rich compost. This would answer well: to every ten barrowloads of brown fibrous loam add two barrowloads of fresh horse manure, two barrowloads of lime rubbish, two barrowloads of "burn-bake,"

half hundredweight of bone-meal and half bushel of soot; apply liberally. A poor, dry root run favours the spread of mildew, so also does reckless ventilation, more especially when this takes the form of opening the front lights wide during the prevalence of bright sunshine and an easterly wind in May. Sulphur fumes will destroy mildew germs, but must be applied when there is no leaf growth. This might be included in T. R. White's attempts at getting rid of the mildew, which must be very determined if he is to succeed: Mix flowers of sulphur with milk and apply this in the form of a paint to the hot-water pipes. Shut up the house and make the pipes hot enough to generate sulphur fumes strong enough to drive a man out of the house. This would kill any growing Vines or plants, but would not injure trees or Vines at rest. Next spring, a close look-out for any signs of mildew should be kept, and directly detected (there is almost certain to be a little of it) sponge the affected parts with the mildew composition diluted as before advised.—W. I.

**The Crystal Palace fruit show.**—The R.H.S. authorities have met with severe criticism over the arrangements of this show. It should be understood that the criticism applies only to the competitive portion of the show, all that part devoted to honorary exhibits arranged in precisely the same way answering admirably. But I am informed that the arrangement of the tables was that of the Crystal Palace management, and the R.H.S. officials had to make the best of it. That it did lead to many unfortunate mistakes there can be no doubt, and it is most obvious that another year a far more desirable table arrangement must be made. With regard to the schedule, I entirely agree with the criticisms recently expressed. It is far too stereotyped; we want classes for green or late fruits especially, and rather less desire to see or encouragement given to mere show fruits. We want classes for flavour also, both in Apples and Pears, the latter especially. We want to have our dessert Apples grouped also, having classes for Pippins, Russets, Pearmains, &c.; then a class for others not so designated, and that would enable Court Pendu Plat, Margil and others of our most delicious Apples to be shown. We might also have classes for colour, as so much stress seems to be laid on that feature. The single dish classes are very monotonous and uninteresting. I hope we shall see a very different schedule next year.—A. D.

—I am pleased to see the remarks in THE GARDEN (pp. 302 and 303) on the arrangement and judging at the above. I had no idea that there could be such haphazard management by the leading society, who recently was formulating a new judging scheme, and under their guidance better things should have been expected. Who is to blame? Are there too many judges, and are they tried men in their several departments? Are the officials responsible for the staging, or is it the council? Strange to say, the fruit committee was not consulted as to the schedule, as it was not brought before them, so I hope Mr. Prinsep will exonerate them. Perhaps the society goes outside to get its schedule framed in the same way it recently got a committee together for a special purpose. It is not necessary to do so.—F. R. H. S.

**Manuring Gooseberry trees.**—How often in large and small gardens does one see Gooseberries totally neglected as regards manure. They are allowed to grow in one place for many years, and they produce weak wood with abundance of sucker growth. These trees in light sandy soils suffered badly this season from red spider. Now is a good time to apply a good mulching of rotten manure, as the trees will soon absorb the food at this season of the year. Impoverished trees will well repay removal to new quarters. It is surprising how well old or large trees bear removal—they take a new lease of life. If given fresh soil and well mulched afterwards, they start into growth next year with more vigour, and there is less trouble another season with insect pests. In wet, low-lying situations the old trees get covered

with Lichen. A good dusting with lime before manuring will check the growth of the Lichen. A little attention to the trees now, when time can be spared, will be well repaid by the crop later on.—S. H. B.

**Peaches in town gardens.**—In THE GARDEN for October 19 (p. 303) "E. M." alludes to the satisfactory crops of Peaches he had seen in town gardens. I can support his statement, for I have frequently seen perfectly healthy trees carrying good crops of fruit in such gardens. The greatest objection I have seen in the fruit produced in them is that it is generally of a bad colour, owing to the smut and smoke. I used to grow both *Ca h33* and Nectarines well at Dingwall House, Croydon, thirty years ago, but the amount of syringing required to keep the foliage and fruit free from smut was enormous; the flavour, too, was very good. I know, too, that in such gardens the trees require a large quantity of water at the roots, even in ordinary seasons. The greatest hindrance to getting a crop of fruit is frost when the trees are in bloom. In such sheltered gardens as we find in towns the blossoms open quite a fortnight earlier than those in the country, and if the bloom is not well protected the crop is lost. In a mild time I have seen all the blossoms on unprotected trees destroyed in the middle of February. Peach growing in town gardens will not be always successful, but a painstaking cultivator may in fairly good seasons safely reckon on getting a crop of fruit.—J. C. CLARKE, Taunton.

**Apples and canker.**—In the early part of the year I wrote that I had noticed cases where canker had attacked Apples on the Paradise stock while those on the Crab were free from the disease. This statement was received with incredulity by a correspondent, who gave reasons why the Paradise stock would enjoy greater immunity from canker than would the Crab. While not professing to be equally experienced, or to treat them otherwise than as possible exceptions that might prove the rule, I gave two instances in which the reverse was the case. I have lately visited a garden where there are several large bush trees of Blenheim Orange. Some are on the Paradise stock and some on the Crab. Those on the Crab are in good health; those on the Paradise badly cankered. The garden alluded to is on a hillside with a slope to the south, and the soil is a deep heavy loam. I would not say that canker is generally more prevalent on the Paradise than on the Crab stock; indeed, I believe the reverse to be the case, but there are instances when this is so.—S. W. F.

#### THE COMMON SWEETWATER GRAPE FOR EARLY FORCING.

I HAVE not the least doubt I shall be thought lamentably behind the times in recommending this Grape for early forcing. Those who know the merits of the Sweetwater will bear me out when I say it is far superior to Foster's Seedling. The berries of the Sweetwater may not be so fleshy, but the juice is delightfully sweet and refreshing, and nine people out of ten who regard flavour as the primary point in a Grape would prefer it. Gardeners are, I think, in a great measure to blame for this, as the much larger Foster's Seedling has been allowed to push it on one side. This is, in fact, clearly a case where size of bunch and berry has been placed before superior flavour, and I am quite sure if gardeners would ones more introduce it into their early vineries they would not regret it. Early forcers of Grapes are well aware that, so far as appearance of the berries goes, Foster's Seedling is ready for table a fortnight in advance of the Black Hamburgh when grown in the same house, but they may not know that the common Sweetwater can be had perfectly ripe and sweet a fortnight before Foster's under the same conditions. Thus two points are gained in favour of the smaller Grape: the former is a gain in time, and the second (the more important of the two), a

crop is secured that will give pleasure to those who may have to eat it. The common Sweetwater is easily forced, sets its berries with the greatest freedom even in the dark, dull weather of mid-winter, and bears regular crops. Thirty-five years ago when I was at Kersney Abbey I had no difficulty whatever in getting the common Sweetwater ripe early in April, although the heating medium was only a fire and the roots in an outside border. At that early date the bunches were of a respectable size. But better than all was the report of my employer that the flavour was excellent. I am not asking anyone to root out established Vines to make room for this one until he has proved whether I am right or wrong about the merits of the Sweetwater, as there are plenty of gardeners who have the convenience to grow a few plants in pots, and so prove the matter for themselves.

Taunton. J. C. CLARKE.

OUTDOOR GRAPES.

THE discussion on the culture and management of Grape Vines in the open air is likely to prove as interesting and useful as that on outdoor Figs. In my opinion the decline and death of a great proportion of Vines in the open soon after the seasons changed for the worse were to a great extent due to the injudicious manner in which the Vines were pruned, trained and thinned in summer. Many of the most luxuriant and productive Vines belonged to those who had no definite knowledge of their requirements, the only attention accorded being a rough-and-ready sort of pruning in spring and little or no thinning out and shortening back of lateral growth in summer. Under these conditions the Vines fruited and even ripened fair crops of average-sized bunches, but as soon as dull summers and wet autumns set in, the wood of these Vines, being pithy and unripe, soon succumbed to frost of average severity. I know of Vines here and there which, being in better hands, have been regularly pruned and stopped much as indoor Vines are, and they are still living, and, although old, are fairly vigorous and productive. Essex was famous for Vine-clad walls and cottage roofs twenty years ago, and I well remember a very profitable one which grew on a kind of rough trellis about a foot from the roof of a labourer's dwelling, the Vine also covering the whole of the front thereof. The variety was the common white Sweetwater, of which Mr. Iggulden speaks, and the profits from the sale of the Grapes each year went far towards paying the rent both of house and garden. In the gardens of Lord Petre in the same county, extra good crops were borne on outdoor Vines year after year. The Vines occupied the south side of the lofty bothy and shed and fruit rooms, one being a Black Hamburgh and the other a Sweetwater. In good seasons, with a maximum amount of sunshine, I have known the best bunches enclosed by muslin bags to protect from wasps and flies, and used for dessert. The main stems of these Vines were taken some little distance up the wall, horizontal rods being then trained right and left the whole length of the building, upright rods being taken from those at every 4 feet, the close spur system of pruning being practised. The border was narrow and shallow, and the roots had gone beyond it and permeated a large space of gravel roadway opposite. The narrow border was mulched and fed several times with farmyard liquid. The wood the Vines made in such a medium was only moderately thick, and in autumn brown and hard, and quite capable of passing through a sharp winter uninjured. Were I planting outdoor Vines I would follow the above lines exactly. I do not consider that the system of running up new rods yearly and cut-

ting out the old is as safe as adhering to the old rods and close spur-pruning, thorough ripeness being less certain with the young rods in a variable climate like ours. Provided the improvement in our summers and autumns continues, I think it only needs time for open-air Grape growing to again become general. A variety called Gamin Noir, which has small black berries, and is extensively grown in the French wine districts, is now highly recommended for outdoor cultivation. Gamin Noir is also one of the principal varieties grown in the Marquis of Bute's vineyard at Cardiff, wine from the vintage of 1881 having recently been sold by auction at £5 15s. per dozen.

J. C.

SHORT NOTES.—FRUIT.

**Pear Comte de Lamy.**—Mention is made by "J. C." (p. 303) of this Pear. I, too, have much to say in its favour, as it is one of the few Pears that succeed here in the open. As a freely-grown pyramid it seldom fails to give a full crop of fruit, generally of good size and excellent flavour.—E. M., Hauts.

**Pear Duchessed'Angouleme.**—I gathered today (October 19) from a short cordon-trained tree growing against a south wall one fruit of this Pear, which turned the scales at 2 lb. 2½ oz. In circumference it measured 15½ inches, and from the stalk end to the eye it measured 17½ inches. To me this seems an unusually large fruit for the variety.—E. M.

**App'e Ribston Pippin.**—The fact of this Apple being so largely represented at the late fruit show at the Crystal Palace hardly proves that it is more popular. I think the real reason for such a large number of dishes is the fact of the present year's crop of all varieties being so much in excess of that of previous seasons. My opinion is that the Ribston is less popular than it was. Trees are not planted so largely as they were some few years since.—E.

CHRYSANTHEMUMS.

NEW VARIETIES.

JUDGING from the appearance of several new kinds fast developing, this season is likely to be remarkable for the large number of new, distinct and desirable sorts. The Japanese varieties will largely preponderate of course, and rightly so, as they are by far the most appreciated for any purpose. The following I have noted as being worthy of consideration by cultivators in the future. In describing new Chrysanthemums I am much guided by my own ideas of the colour of each as found in the blooms before me rather than from descriptions obtained from the growers. **Bocling** is a new variety of the Japanese class, growing a good deal like the **Zealandia**, but with a more upright habit and a more compact flower. It is an improved **Mrs. Anna H. Weston**, a kind which it resembles. The blooms are massive, nearly 8 inches in diameter; the florets incurve loosely, giving it much character, white, with just a tinge of lilac or blush in the later-formed blooms. I should strongly advise growers of large blooms to make a note of this. **Zealandia**, as its name implies, was raised in New Zealand; it belongs to the class known as Japanese incurved, the florets broad, making a massive flower. The colour, silvery pink, is pleasing. When grown early it has but just a shade of pink in the centre. It grows 6 feet high. **W. G. Newitt** is another American-raised variety I noted last year favourably. This year it promises to be equally fine. The long pure white florets droop most gracefully and informally. The foliage is massive, and contrasts well with the bloom. It is one of the best of white-flowered Japanese Chrysanthemums. The treatment required to obtain the finest blooms is to pinch the plants early in April in the same way as Mrs. Falconer Jameson, and take up from this check three stems, allowing each to carry one bloom. Plants 3 feet high, surmounted with three charm-

ing flowers, are then obtained. **Hairy Wonder** appears to be fulfilling the opinion formed of it last season as to its being the best in the coloured hirsute section. **Mrs. J. George** is sent out from America with a great flourish, and was regarded as being a great gain upon existing varieties. At present I am unable to note any distinction whatever in growth or bloom from **Florence Davis**. **Mrs. W. H. Lees** is behaving in a desirable manner this season, and I shall expect to see this flower exhibited in perfect form on many occasions. Nothing could be more promising than the growth of the plants. **Abbe Mendenhall** is an American-raised variety of dwarf habit, capital blooms being produced on plants but 3 feet high. The long, narrow petals incurve slightly at the point; the centre is deep yellow, but with age the petals change to primrose—a full massive bloom. **Lily Love** was sent out in 1894 and evidently possesses much character. I do not know any other variety of the same form. The tubular petals are long and narrow, pure white when fully expanded, but green in the centre while developing; height 3 feet. **A. H. Fewkes** produces full-sized blooms upon plants but 2 feet 6 inches high. It is an incurved Japanese. The plants are clothed with extra large deep green leaves; a most promising variety. **Mrs. J. R. Taylor** is supposed to be of the **Golden Dragon** type of bloom, with long, curly petals. Early blooms do not show it in this character at all. At present it is a massive flower, having rather short incurving petals, many being split and forked at the point. In colour it is a dull white with a distinct primrose centre, which will no doubt pass away with age. It grows 5 feet high, having extra long peduncles. **L'Esere** is developing blooms in a satisfactory manner; the long, somewhat drooping florets are massive. **Mrs. C. E. Shea** is giving most promising blooms from plants but 4 feet high. It appears to warrant the high opinion formed of it last year. **W. Fyfe**, but 3 feet high, is carrying plump, well-formed buds; the same may be said of **William Bolia**. The former is a representation of the once favourite **Belle Paule**, the latter a rich crimson, with silvery reverse. As a rule the red and crimson-coloured varieties have a golden reverse; in **W. Fyfe**, therefore, we may expect a departure. **Mme. Adolph Chatin** and **Mme. Ad. Moulin** both promise well. The former is a massive incurved flower of the purest white; the latter has much longer petals, which incurve at the point, cream centre, fading with age. **E. MOLYNEUX.**

**Chrysanthemum M. Aug. de Lacvievier.**—

This variety has been in the hands of English cultivators for the past two seasons, but as yet it is not so generally known as it deserves to be.

It is a Japanese incurved variety, with broad grooved florets, the inside a warm terra-cotta, the reverse rich golden rose. This Japanese Chrysanthemum is most disappointing. The blossoms cover much space, but they are very "thin." Early flowers have quilled or fluted florets. The colour is rose, shaded gold.

**Chrysanthemum Louise.**—

This is a Japanese incurved with broad grooved florets, the inside a warm terra-cotta, the reverse rich golden rose. This Japanese Chrysanthemum is most disappointing. The blossoms cover much space, but they are very "thin." Early flowers have quilled or fluted florets. The colour is rose, shaded gold.

**Chrysanthemum Louise.**—

This variety is first rate for producing blooms in October. It is in fact one of the noblest of all Chrysanthemums, in colour a lovely blush shade. It is a Japanese variety of loosely incurving formation, the flowers on disbudded plants being 5 inches to 6 inches across and of similar depth; the florets broad, wax-like, and rich. Not the least of its merits is the dwarf growth and abundant foliage. Plants in 6-inch pots make capital specimens, such as would be useful for the conservatory.—H.

**Chrysanthemum M. Chas. Molin.**—

Among the most promising of last year's novelties from France was the above-named, and the blooms of this season already bear out its excellent qualities. The colour is bronzy yellow, the latter shade most

characteristic of the centre portion of the flower. In form the flower is drooping, large, and very double. The plant is of medium height with distinct and fine foliage.—H.

— This belongs to the reflexed type of Japanese. The florets are flat, broad, and of good substance; the blooms well built and of full size. The colour varies according to the "taking" of the buds. From the early-formed buds the centre of the flower will be golden yellow, the base heavily flushed with crimson-bronze. Later formed blooms will have a mixture of yellow, crimson, and bronze. Altogether it is one of the best varieties in the Japanese section of last year's introduction.

**Chrysanthemums at Ambleside, Wimbeldon.**—Well-grown collections of Chrysanthemums are not rare now-a-days, but it is not often one meets with such an exceptionally nice lot as may be seen at the residence of Mrs. Barclay. The leaves are free from disease of any kind, and have a shiny deep green hue which denotes the best possible health. These hang to the pot's rim in most instances, and are large and firm, but not coarse. The stems are not particularly stout, but hard and well ripened. Another thing noticeable is that a badly formed flower-bud cannot be found; each kind in its particular way is swelling in the most kindly manner. The plants are grown to present bold groups in the greenhouses, but if any go to the exhibitions I shall be surprised if they do not give a good account of themselves. The collection is rich in new kinds, as well as the best of the older sorts. Phœbus (chrome-yellow) is grand and thought much of. President Armand, for which Mr. French gained a certificate lately, carries finely-incurved blooms of an old gold colour, with an inside crimson shade of peculiar richness. Souvenir de Petite Amie is a good white flower, and the growth very dwarf. Mlle. Thérèse Rey (white), Eda Prass (blush), M. Pankoucke (yellow) and William Tricker (rose) are a few of the most forward, and are very fine. The mode of growing late-struck cuttings in small pots is followed extensively here, the plants being excellent. They are each from 1 foot to 2 feet high and useful for edging groups.—VISITOR.

**Dwarf Chrysanthemums.**—Will some reader kindly give me the names of twenty-four new Japanese Chrysanthemums, in various colours for good-sized blooms? The height of the plants must not exceed 4 feet 6 inches, or 5 feet.—ARTHUR NOTTINGHAM.

\* \* The following kinds will not grow beyond the height desired, that is, provided ample room be given the plants in the summer-time and crown buds be selected. Most of the sorts may be expected to produce about half a dozen good-sized blooms to a plant. Boule d'Or (new), buff; Cecil Wray, yellow; Commandant Blusset, amaranth crimson; Guirlande, shaded white; Hairy Wonder, buff yellow; Louie, blush-white; Mephisto, red and yellow; Mrs. E. S. Trafford, bronze-rose; Mme. Ad. Chatin, white; Mme. Ad. Moulin, white; M. Gruyer, pink; M. Ch. Molin, bronze-yellow; M. Pankoucke, yellow; M. Georges Biron, crimson; President Armand, crimson and old gold; Niveum, white; Phœbus, yellow; Pallanza, yellow; Richard Dean, crimson; Souvenir de Petite Amie, white; Thos. Wilkins, yellow; Thos. Dennis, red; Wilfrid Marshall, yellow; and Wm. Bolia, amaranth-crimson, will, we think, answer your purpose.—Ed.

#### CHRYSANTHEMUMS IN OCTOBER.

THE recent exhibition at the Aquarium was not over-rich in varieties which are at their best in October, but in too many instances they were merely the ordinary November kinds forced on by selecting early buds and thus presenting specimens in many cases entirely out of character. This is a pity, as growers should be alive to the fact that a selection of good sorts may be obtained without such manipulation, which I venture to say would show to greater advantage than most of the blooms at the time in question. That the late show made a splendid display collectively I admit, but I have seen better Chrysan-

them flowers during the month of October. There was an especial want of colour; light shades predominated everywhere. The variety E. Molyneux was absent, at least I did not see a good bloom. Wm. Holmes is despised because a trifle small, but I have seen fine showy blooms of this old sort at previous shows in October which would have materially assisted in giving colour at the late one. The rich yellow Sunflower was missing, nor was Avalanche in anything like good form. Mlle. Thérèse Rey, again, was sparsely shown, and I did not note a flower of Mlle. Lacroix. New this is a true October variety, and is charming when well grown. Elaine, the purest of whites, is better than many of the newer varieties, and is at its best during the month. Louise was very fine, and is naturally early. Hamlet is a good early kind of a taking cerise shade, which is all but forgotten. Wm. Tricker is also early and fine. Mme. Edouard Rey makes a handsome show flower in October. Blooms of Thomas Wilkins were among the best at the late exhibition. This is a very fine yellow, although a bit dull in colour. Kentish Yellow is also excellent for early flowering. M. Ch. Molin, a newer sort, is good in October. The same may be said of that remarkably handsome kind M. Aug. de Lacvievier.

For the supply of a quantity of cut flowers, Mme. C. Desgrange is a most useful white at this time of the year, the yellow sport G. Wernig being an excellent companion to it. A variety of especial value is Rycroft Glory. I have seen this in fine condition several times this season. The bronzy yellow colour is a valuable shade, which is remarkably rich by gaslight. This variety makes a nice bush plant, but is not adapted for producing large blooms. Elaine is now in full flower; this is not surpassed for the purity of its white. Lady Selborne is also an excellent white, the yellow variety of it being equally useful. Source d'Or is nearly out. This is still the best of its shade, and a favourite with all because of the richness of its colour under artificial light, and it mixes well with whites and yellows. The early sort, Wm. Holmes, supplies a fine crimson, which will be difficult to beat. I have mentioned Mlle. Lacroix as a show bloom. This is also most charming for cut flowers; it produces smaller blooms in great abundance, and they are always elegant. Somehow the yellow Lacroix or Mr. C. E. Shea has not been so popular as the white; still it gives the same grace of form and is equally as free as the type. Louise should be tried in the bush form without disbudding. I am sure this pearly-blush variety would find admirers, and the dwarf free growth is suitable for such a mode. H. S.

#### NOTES ON CULTURE.

WITH the present extraordinary hot weather the chief aim of the cultivator will be to keep the plants that are intended to produce large blooms as cool as possible. In vineries, Peach houses, greenhouses and such structures the plants can be kept cooler than when standing in the open under the fierce sun. The plants should be given as much space as possible to avoid an early loss of their leaves. The development of the blooms must be hindered by a premature loss of leaves; it therefore behoves all cultivators to retain them as long as possible. Shade must be provided in some form or other, not only for retarding the flowers, but for their preservation. Under the shade of Peach trees and Vines artificial shading is not needed. In the greenhouse the ordinary roller blind must be kept continually down whenever the sun shines upon the house. In the absence of temporary shading the glass should be covered with lime, to which is added some flour to make it adhesive. Clay made into the consistency of paint is a good shading material. All the ventilators and doors should be opened wide both day and night, admitting a free circulation of air. All plants that have not opening buds should be syringed once or even twice daily during this extra heat. Not only does this render

the atmosphere less arid about the plants, but the opening buds unfold more easily. Mildew must be sought after rigorously. Where sulphuring is necessary syringing the leaves must cease. Brown sulphur is the best, being the least objectionable in colour and quite as efficacious as that of the ordinary shade. The plants must receive regular attention in watering. They will not require so large a supply as when standing out of doors, but they must not suffer from want of it. Examine them carefully twice daily and apply it only when the soil is approaching dryness. Some care is necessary at this stage in the employment of stimulants. Giving these too freely or too strong may cause the blooms to drop at a later stage. Plants that have thick unripened stems, heavily clothed with large succulent green leaves, require next to no food. Plants that have medium-sized stems, fully matured and corresponding foliage, will be all the better for some stimulant in liquid form. Plants belonging to this latter category are, as a rule, well supplied with fibrous roots, and abundance of them on the surface. It is these that revel in supplies of liquid manure. E. MOLYNEUX.

#### SHORT NOTES.—CHRYSANTHEMUMS.

**Chrysanthemum Mme. Albert Menier.**—A Japanese of the early type, narrow florets; colour pure white, centre tinted soft sulphur-yellow; good flower-stalks, very useful for cutting.

**Chrysanthemum Prefet Cassagneau.**—A new early-flowering variety of a deep rich velvety crimson colour. An early Cullingfordi, one of M. Simon Delanx's novelties, sent out last spring.

**Chrysanthemum M. Backmann.**—Another new early Japanese. Blooms rather large; the florets are long, and the colour a warm shade of golden terracotta, suffused salmon, reverse golden, forming a ball in the centre.

**Chrysanthemum Mme. Emile Nonin.**—An early Japanese, very free, and comes in clusters; long florets, of a delicate shade of pale sulphur-yellow, tinted lemon-yellow in the centre. A pretty flower of medium size.

**Chrysanthemum Meduse.**—Also an early-flowering Japanese variety of this year's introduction. The colour is golden amber, tinted crimson-bronze, a rich and effective tint. Rather large in size, and free blooming.

**Chrysanthemum Mme. Armand Groz.**—A Japanese early variety. A pretty little flower, but the flower-stalks are rather weak; long, narrow, revolute florets; colour pale primrose-yellow, faintly tinted salmon in the centre.

**Chrysanthemum Lady Eether Smith** is recommended as an October flowering variety, and it certainly possesses all the characteristics of a deserving sort. The pure white, long and broad florets incurve somewhat irregularly.

**Chrysanthemum Mme. Henri Jacotot.**—A Japanese early variety, with long flower-stalks and rather large in size, long intermingling florets, pointed at the tips; colour white, suffused pale purple-mauve, reverse same colour; delicate and graceful. A French seedling.

**Chrysanthemum Boule d'Or** (Calvat's variety). Although appropriately named, it seems a pity that this name should have been chosen for this new Japanese. It is quite true that the old variety once so deservedly popular is seldom seen now-a-days. The new-comer has all the points of a good flower. The petals are medium in width and perfectly, if loosely, incurved. The colour is pleasing, the reverse being a nankeen yellow. The surface is gold at the base, with a golden suffusion.

**Chrysanthemum Philadelphia.**—This much-advertised American seedling was raised by Mr. H. Graham, and it holds the unique position of being the only American variety that has ever had the silver-gilt medal of the N.C.S. conferred upon it. When shown last autumn at the Aquarium it was a large white Japanese incurved, with lemon-tinted tips. I saw some opening buds of it a week ago on some very dwarf late-struck plants, and the colour was a dirty yellowish white. This defect, however, may pass off as the flower expands.—H.

## CHILLINGHAM CASTLE.

CHILLINGHAM is on a ridge of land nearly 1000 feet above the sea in a rocky moorland district, intersected by deep and beautifully wooded glens. It is about fourteen miles from Alnwick, and the visitor who would see the beauty of this northern district should travel by the branch line that runs from Alnwick to Cornhill, leaving the train at Ilderton. From here for a distance of about three miles a charming valley is traversed, a district where the fields and roads are bounded by good hedges and the Sweet Brier is abundant, and borne down with the weight of its heds. Here, as in the south, the Sweet Brier was flowering in mid-October, and the effect of its long shoots, scarlet with fruit,

original structure. It has a tower at each angle, and surrounds a courtyard, in which is preserved a famous toad-stone—a block 5½ feet long, over 2 feet broad, and 1 foot 3 inches thick, the cavity in which the living toad was discovered many years ago being several inches in depth. Originally this stone formed the hearth of a fireplace in the castle, and a particular spot was noticed to be always damp, which could not be accounted for, so the stone was removed and the toad discovered.

The illustration here given shows but a small part of the handsome terrace garden, with its beautiful retaining wall 120 yards in length. The wall alone was a perfect picture at the time we saw it. In one part it is covered with Ivy; elsewhere a large bush of *Berberis vulgaris*

We must not omit to mention the wall at the end of the terrace, which is partly overhung with trees, its face in a great part hidden by a lovely veil of that pretty native Fern, *Asplenium Trichomanes*. From here, ascending a flight of rough Moss-covered steps, Grass slopes adorned with trees make a pleasant shady corner, and we pass on to the south front of the castle, which has a broad gravel walk in the foreground and a lawn that merges into the park and the adjoining pastures.

The park, about 1500 acres in extent and surrounded by a stone wall, is the home of the herd of wild cattle for which Chillingham is famous, also herds of red and fallow deer. The park landscape is rich, wild and romantic, and near to the castle are delightful wooded

Chillingham Castle, Northumberland. Engraved for THE GARDEN from a photograph by Mr. J. T. Hopwood, 5, Bury Street, St. James's, S.W.

falling outwards from the Hawthorn hedge, was very beautiful. From the public road the castle is reached by a broad drive, which passes through an avenue of Lime trees backed up by woods on either side, from which one emerges into a broad open clearing with a high wall on the right that forms the supporting wall of the flower garden above, and on the left rich Grass adorned with a few trees slopes away down to the woodland again. This, the carriage front, is bold, simple, and dignified, a fitting approach to a noble building whose history is bound up with the Border warfare of earlier days. Chillingham is the home of the Earl of Tankerville, and while some of the building is of great age, it has been extended and enlarged considerably, little remaining of the

had grown several feet higher than the wall, and was a mass of colour with its crop of berries. Clematises hung in festoons, with Ivies, Vines, a fine plant of the climbing Hydrangea, Pyracantha and other plants, while in front of the wall a long border was planted with some of the best hardy and tender flowers. The flower beds, although somewhat angular, are of sufficient size to permit of bold grouping, and this is so well done that the form of the beds is less seen, and the blending of the colours of the many flowers was well carried out. Many hardy plants are here well grown, from the stately Delphinium down to Hepaticas. Choice wild Roses and hardy Fuchsias give height and boldness to the arrangement, and the whole terrace in summer and autumn days is gay with colour of the truest kind.

denes through which runs a little stream whose rocky bed forms a series of miniature falls between steep banks garlanded with many native Ferns. Beyond lies a large, undulating, rich Grass valley, and from this the ground rises higher and higher; the scene is changed with the elevation, and one looks upon a great dark slope of Pine wood, whilst above this, clear against the sky, is the summit of Ros Hill, about 1200 feet high. To look out from Chillingham upon its magnificent park is a picture that brings a sense of satisfaction into the mind, but a finer picture is that from the summit of Ros Hill for a standpoint. The climb is a long one, as the way lies outside the park wall for safety from the cattle, but the path passes through beautiful natural woodland of Beech, Oak, Birch, and Moun-

tain Ash rising out of carpets of Ferns, thence emerging into pastures of deep rich Grass, wherein stands an ancient relic of Border strife and cattle-raiding in the old cattle keep, into which the animals were driven, secured, and defended. From here a steep climb begins up a craggy slope, so exposed and wind-swept, that even the Heather scarcely raises its head, but spreads in carpets on the ground like the mossy Saxifrage. When the summit is reached a glorious view is obtained of land and sea, barren moors, fertile valleys, and wooded hollows. The long line of the Cheviots, with the highest peak hidden in a cloud, bounded the view in one direction. The river Tele, as a silver streak, wended its circuitous course through a valley till lost to view in the district of the Tweed. Flodden Field lies within easy range of the eye, whilst of other castles, besides Chillingham lying almost hidden in its surrounding trees could be seen those of Alnwick, Warkworth, Duustanburgh, Bamborough, Copland, Haggerstone, Norham and Ford, with Holy Island, the Farne Islands, and a long line of seacoast.

Returning to the castle grounds, a pretty way lies through the dell, where tree and bush, Fern and flower blend into a series of combinations that vary with every turn and change with the seasons, beginning with the Snowdrops and ending with a rich feast of colour in autumn fruits and tinted leaves.

The kitchen garden, like the flower garden against the castle, is a good one, with fine walls, large open quarters for vegetables and broad borders of hardy flowers that make the spot gay whilst providing flowers in abundance for cutting. These departments, together with the glass, are ably managed by Mr. R. Henderson, the gardener. The glass erections are limited in number and so confined in scope, that plants and fruit have of necessity to be grown together in the same structure, and it is done admirably. We saw excellent crops of well-finished Grapes, whilst one vinery had its back wall hidden with zonal Pelargoniums trained upon it, reaching to the top, and 14 feet in height. They here bloom in profusion, particularly in early summer before the Vines restrict the sunlight. The varieties were Purity, Vesuvius, Polly King, Henri Jacoby and Colonel Pearson. In another vinery Figs cover the back wall and are trained down the roof about 2 feet to meet the Vines. They also fruit admirably. A house devoted to Peaches contains fine trees of Priucess of Wales, Noblesse and others, whilst upon the back wall here was a magnificent trained specimen of the Ivy-leaved Pelargonium Souvenir de C. Turner, and a fine plant of Smilax aspera. Pears are finely grown on the kitchen garden walls, and some of the best Apples are here grown on walls. The Apple crop has been an exceptional one this year even in northern gardens, and in the fruit room we saw an admirable lot of fruit grown upon bush trees in the open quarters of Emperor Alexander, Peasgood's Nonsuch, Lane's Prince Albert, Warner's King, Yorkshire Beauty, Northern Dimpling, and others. Annuals are generally seen to better advantage in cool northern gardens, and one charming border of them was delightful with the blue Nemophila for an edging, backed up by a broad line of the spreading rose-flowered Saponaria calabrica, and behind this a line of the graceful flesh-white Gypsophila elegans.

## II.

**A profitable glass house.**—It is not every gardener who has the advantage of a good range of fruit and plant houses, where successional supplies can be brought on with comparative ease,

yet good results are often achieved under adverse circumstances by the exercise of forethought. One of the most profitable houses that has come under my notice is a somewhat lofty lean-to, having lights some 4 feet wide, slanting from the top of the house at the back, these also serving as ventilators and admitting a good deal of extra light to the back wall. Trained to the latter are Figs of various varieties, grown in narrow slate boxes arranged on stout supports some 3 feet from the base. These, after reaching the top of the wall, are allowed to travel a short distance down the main roof facing the south, being fastened to wires. Capital crops are annually obtained from these trees, the fruit being gathered from the top of the slanting stage, which occupies the body of the house. In each corner of the house, close to the front lights, another slate box is fixed, a Peach being planted in one and a Nectarine in the other, these being trained to a trellis over the pathways at each end of the stage. At this season of the year, when the fruit trees are at rest, the stage is filled with Tree Carnations and minor side shelves with double and single Primulas, Cyclamens and Solanums. In spring, when the Carnations have done blooming and the cuttings are taken, the stage is cleared and sometimes refilled with Tea Roses, which in their turn are placed in cooler quarters to harden off, pot Figs being then taken in to fill their place. A stout shelf along the front of the house accommodates a row of early pot Tomatoes, the plants being trained to a temporary trellis suspended on hooks over the front pathway some 15 inches from the glass. The quantities of fruit and flowers produced in this house from January to December are astonishing, and the various arrangements here described might be profitably imitated in many places lacking space and convenience.—J. C.

## FLOWER GARDEN.

### DAFFODILS IN ORCHARD AND WOODLAND.

THE above-named positions are perhaps the most serviceable for the proper utilisation of the Narcissi. Both phases of gardening are too often found suffering absolute neglect, at least in respect to those plants to which this note directs attention. It would be difficult, if not impossible, to name any position in which many of the Daffodil family appear so beautiful, so natural, or so much at home. The very Grass, the trees, and, above all, the natural virgin soil of such places are so much theirs by nature, that one wonders why Narcissi are not planted in their thousands where such places exist. What charming vistas may be opened up in a bit of woodland where such gardening is successfully carried on. From quite early in the year when such places may be aglow with many bulbous plants till quite late in the year, when day by day the Dogwood seems to grow more intense in its colouring, should there be something of interest in foliage or in flower. I well remember a very pleasing and interesting bit of woodland gardening at Sydenham many years ago in the gardens of Mr. Latimer Clark; indeed, it was a portion of the original Dulwich Wood, where Oak was the staple timber and Hazel the principal of the undergrowth. The soil was a yellow loam and rather heavy. Some three acres or more of this woodland portion were made very beautiful with a large variety of inexpensive plants. In this way the sides of the woodland walks were each year aglow with quantities of Primroses quietly nestling among the Grass, and later with Wood Hyacinths, Anemones, Narcissi, Lenten Roses,

Tulips, Lilies, Bamboos, and other things, including several forms of *Helleborus niger*. What gives the charm to this phase of gardening is the natural surroundings of the whole. This applies with equal force to naturalising in orchards and meadows as it does in the woodland and wild garden.

Among the double Daffodils there are none to beat a good strain of the old yellow *N. Telamonius pleuus*. I say a good strain, because there is a wide difference even in double yellow Daffodils, one strain being very much addicted to disease, while another growing in the same soil and under similar conditions seems proof against disease. In spring-time in grassy meadows or woodlands the golden blossoms of this Daffodil are most effective, and the bulbs continue a long time in health and vigour. For such work it is much best to plant fair-sized bulbs at the start, because the progress and increase of the bulbs are much slower than in the deeper tilled and richer looser soils of the garden. Many kinds of Narcissi, for example, *N. pseudo-Narcissus*, *obvallaris* and *Ard-Righ*, that are only rarely a success in ordinary garden soils, often flourish in the soil of the pasture or meadow—possibly because the soil is free from the often over-abundant added manures of the ordinary garden, which tend in the direction of loose, flabby tissue only. The meadow land, on the other hand, is of that uniformly pure nature, such as Nature alone provides. Then again there is uniform solidity of the soil surrounding the bulbs and roots, and these conditions combine, I think, to the production of uniform solidity in the bulbs themselves. Ensuring in the first place a more natural slow growth, we get in the result bulbs of small proportion, but firm and hard as a nut; and it is just such bulbs as these that may remain for years in the soil of the meadow pasture, orchard or woodland without developing disease. In the course of years I have had experience of many hundreds of thousands of collected Narcissi, mostly *obvallaris*, *princeps*, and at least two distinct forms of the old double yellow, all collected in a wild state on British soil. Coming to hand in the fall of the leaf, I have had opportunities for observation not obtainable otherwise, and the first thing that strikes one is the uniform smallness of the bulbs, next the comparatively few flowers they have borne, and third, the great depth they have been in the earth. But the greatest pleasure of all is the perfect immunity from disease. The foliage a full deep green to its very tips and a good wig of roots below, accompanied by a nut-brown skin in the Tenby Daffodil, are the surest indications of perfect health. And in a very similar way do these bulbs behave in our orchards and woodlands. In such places as these they give no trouble beyond the original planting, and in spring-time may be seen in all their freshness and beauty.

Especially suitable to the places named are such as the Lent Lily (*N. pseudo-Narcissus*), to be obtained at a mere trifle per thousand, and equally cheap is the old Pheasant's-eye Narciss, which is most showy in the grass, while its late flowering will afford a succession to earlier kinds. This kind has long stems and stands well above the growing grass, whilst its pure and fragrant flowers are very telling. Other kinds equally well suited are the bulk of the numerous single forms of *incomparabilis*, *Leedsii*, with its pure white starry flowers, *Burbidgei* and many others. For very early work the Pyrenean kind, *pallidus precox*, must not be forgotten, and it is quite possible it may be established in such places with greater ease. Then again, *princeps* is an excellent kind, a

well as obvallaris, Ard-Righ and maximus; and lastly, the double yellow *Telamonius* is invaluable; indeed, there is no limit to suitable kinds. At the same time many of the very cheapest are among the most useful. By securing such as these, a good display may be obtained in a few months from planting. Once a start is made and a foretaste of the results apparent, additions will almost be sure to be made year by year, and in this way the hitherto neglected spot in the garden will henceforth be teeming with pleasure and interest. E. J.

#### NARCISSUS PRINCEPS.

THERE are "Daffodils and Daffodils" now-a-days, and when it is advised to plant them in the Grass in the hope and expectation of their thriving and increasing year by year, it is by no means every kind of Daffodil that will fulfil

*Narcissus princeps* at St. Nicholas House, Scarborough. From a photograph sent by Mr. E. H. Woodall.

that fond hope. Nearly all of us must have seen our native Daffodil or Lent Lily in its beauty in woods and moist meadows where, before the advent of these wild-flower-selling days they made a carpet of beauty fit for a queen, but how many or how few of us have succeeded in making them grow in any garden? The common double Italian Daffodil is so coarse beside our native form, that I for one, and no doubt many others, do not really care to plant it in quantity, though it at any rate will grow anywhere in reason. *Narcissus princeps*, called by some the Irish Daffodil, is, however, so beautiful in colour and form, as well as so hardy and cheap, that I think it fulfils every condition required by planters of trumpet Daffodils, and flowers sometimes with incredible abundance. Under the shelter of some large-leaved *Aralia Sieboldi* bushes a group of this Daffodil looks particularly well, and with this shelter comes a little earlier also. Certainly last spring after the severe winter the combination of the broad green fan-like leaves of the *Aralia*-like parasols over the dainty heads of the Irish Daffodil was much admired, and in the extra bright sunshine of last March reminded more than one of the delights recalled by the name of Wordsworth. E. H. WOODALL.  
Scarborough.

**Chrysanthemum Zawadski.**—At first sight this plant in its flowering bears some resemblance to a bluish white single *Pyrethrum*, but a glance at the foliage carries one away to some of the larger kinds of mossy Saxifrages. In this rather strange combination of foliage and flowers the

above plant is not without interest. A good-sized plant in the rock garden at Kew has been flowering very freely during the past summer, though only about 1 foot high. In the deep soil of the border the plant assumes greater vigour, and makes a good dwarf front row plant, being neat and compact.—E. J.

**Statice latifolia.**—Among late summer and early autumn-flowering perennials this broad-leaved *Statice* is too rarely seen. It is perhaps the boldest and showiest of the hardy kinds, and as such deserves a place in every garden where hardy plants are grown. Its requirements are simple, since, given a good deep loamy soil and moderately rich, it attains to perfection. If only one kind were selected, whether for rock garden or border, I would choose this one. Once well planted, it should not be disturbed for several years. If planted in the rock garden, a deep fissure filled with loamy soil to nearly, or quite, 2 feet should be selected, and in such a way that

of exterminating goes on all the year round until a good many beautiful British plants are nearly and in some cases quite gone, as far as their native wilds are concerned. These men who collect know where to find any varieties of British *Orchis*, *Solomon's Seal*, or any other plant you like to ask them for. But it is in Ferns they are most active. If there is a colony of *Osmunda regalis* they will get them in some way or other. Many other Ferns are ruthlessly grubbed up at all seasons and carted away to ornament the back gardens of smoky towns, where, as may naturally be supposed, they have a very brief existence. We have societies for protecting wild birds, and surely our beautiful wild plants might have a corner devoted to them in some of our public gardens.—J. G., *Glasport*.

#### IRIS LORTETI.

THE annexed cut represents one of the most beautiful of the Iris family—in other words, one of the loveliest of hardy flowers and one surpassed by few plants, hardy or tender. The colouring of *Iris Lorteti* seems somewhat variable. In the variety figured the large standard petals are almost white, closely veined with very delicate pale lilac; the falls creamy, dotted

*Iris Lorteti*. From a photograph by Mr. G. Pim, Dublin.

the moisture may be retained for the benefit of the plant. In such a position, and where its large, broad shining leaves may overlap some projecting rock, it will display itself to advantage, and the broad, dense, cushion-like heads of lavender-coloured blossom will be quite a feature. The plant may be increased by seeds, although these are often of slow growth. By far the best mode of increase is by root-propagation in January. By lifting a plant in the border several large roots may be detached. Cut these into lengths of an inch or more and insert in sandy soil around the inside of 5-inch pots. By placing in a greenhouse temperature and keeping dark meanwhile, young leaves will appear in a month or six weeks, when more light may be gradually given. When large enough, pot them singly and eventually plant in permanent places in the garden.—H. H.

**Clematis graveolens.**—After our own native Traveller's Joy is over and but few flowering climbers are to be met with, the blossoms of this *Clematis* are especially welcome and interesting from the fact that they are of a decided yellow colour which is but little represented among the different members of the genus. It is by no means a novelty, having been introduced from the Himalayas in 1771, but it is very uncommon. This *Clematis* is a free-growing climber, and after the flowers are over the large downy heads of seed are very noticeable.—T.

**Exterminating British plants.**—The work of collecting Briers for nurserymen who make a speciality of standard Roses will soon be in full swing, and in Hampshire there are a good many thousands of acres where the collectors of these ply their trade. Unfortunately, they do not confine themselves to collecting Briers, but the work

with reddish chocolate, becoming denser as they approach the stigmas, which, on separating the standards, are seen to be deep reddish brown. It belongs to the *Oncoeyclus* section (of which *I. Susiana* is the best known representative), and blossomed with me on a sunny bank, well elevated, in the early part of this summer. I

am trying Mr. Ewbank's plan of removing the soil during the resting season and keeping the plant quite dry till it shows signs of starting into growth. This charming plant is now fairly cheap, and should be in the hands of all lovers of choice things. For a detailed account of the Irises of this section, see *THE GARDEN*, vol. xliii., p. 130. GREENWOOD PIM.

### LILY OF THE VALLEY.

THE time is fast approaching when gardeners who are required to have an early supply of this popular winter flower will have to place their crowns in heat. A good deal of disappointment is annually experienced either by the crowns refusing to move or by a sudden collapse of the growth when half completed. The cause of failure is generally attributed to the unripeness or unsuitability of the crowns for early work, but more often than not the cause lies in a fluctuating bottom heat. A plunging bed which has one temperature to-day and another to-morrow is not at all suitable for early batches of Lily of the Valley crowns. Many are spoiled by being plunged in made-up beds of leaves and manure, which retain perhaps a heat of 90° for a week or ten days, and then drop to 70°. The former figure is not too high from the time the crowns are plunged until the spikes are well-nigh developed. For some years past I have succeeded well by placing a thin board over the evaporating pan on the hot-water pipes in the Pine stove, standing the pots on this and packing Moss between and around them. An inverted pot is then placed on each of those containing the crowns, and watering with water at a temperature of 90° or 95° is resorted to every morning, as if the soil once becomes dry failure must follow. Since adopting the above plan I have seldom had a patchy lot, as the bottom heat is steady and continual. The inverted pots remain on until the lowermost bells expand, when the plants are removed to a kerb to finish opening. When once out they keep much longer in a temperature of 55°. Many of the beds of Lily of the Valley in the open air fail through sheer starvation. Although this flower needs good drainage, frequently too much leaf mould and light soil are used in forming the beds. Some of the best crowns are grown in Norfolk, and I know that a good deal of cow manure is used. Plenty of space is allowed between the rows, and the second year a furrow is made by a special tool between each row, this being filled with cow manure, which is firmly trodden in and the soil again placed on. Into this the young roots eagerly rush, and fine foliage and crowns are the result. Mulching and watering are also resorted to in dry summers. One most important point in open-air culture is keeping the crowns well above ground in order that the sun and air may mature them. It is said that the imported crowns are much dearer than usual this season, due, I presume, to an indifferent season abroad. This will hinder many of the small growers for market from purchasing, as there is never a vast profit realised from the sale of the blooms, and the public are unwilling to pay any advance on the usual price, no matter what the producer has to contend with in this respect. Although I am no advocate for having flowers out of season, Lily of the Valley is now had by several trade growers nearly all the year round. I am informed it is accomplished by letting the crowns become frozen through in winter and afterwards burying them in the ground some 3 feet or 4 feet deep. Thus they remain in a dormant yet sound state, and are taken out at intervals as required and forced. J. C.

**The poison of *Primula obconica*.**—I have handled *Primula obconica* for upwards of five years. In November, 1891, having read and heard a good deal concerning the irritation caused by this plant to some people, I determined to try the effect on myself. I took some leaves and lightly brushed them up and down the inside of

my right arm from wrist to shoulder. Waiting a few days and finding no irritation, I bruised some more leaves and rubbed them on the same arm in a similar manner, and still there were not the slightest signs of irritation. I then concluded that this plant, although possibly dangerous to some people, was harmless to myself. I continued handling it with perfect impunity, cutting flowers, cleaning, potting, &c., till the spring of this year, when I shifted a batch of this plant (out of bloom), and the next day the back of my right hand was covered with a rash similar to that of scarlatina, and the itching was well-nigh unbearable. Suspecting the cause, I went to a chemist who gave me a lotion, in which sulphur appeared to be largely predominant, and which soon relieved the irritation. Not being quite satisfied, about ten weeks afterwards I brushed the under part of a leaf over my hand and the rash again appeared attended by the itching. In my own case I feel sure that the hairy growth under the leaves and not the pollen was responsible. As far as I can remember, on the occasion of my experiment in November, 1891, the weather was cool and my blood was at its normal temperature, whilst in the spring of this year the weather was very hot. No one else here who has handled *Primula obconica* has suffered in consequence. As for *Primula japonica*, I have had no experience with it.—A. C. BARTLETT, *Dropmore Gardens, Maidenhead*.

**Staking plants.**—It is painful to see the beauty of flowers so often spoiled by the use of conspicuous stakes for their support. Staking is an evil—a necessary evil I admit, but still an evil—which should as far as possible be concealed. Many gardeners (excellent cultivators) seem to take a pride in the size, number and aggressiveness of the supports used by them, and, as a consequence, in such cases the attention which should be focussed on floral beauty is distracted by these inartistic adjuncts. I have lately observed two glaring instances of how staking should not be done. In the first, some splendid auratum Lilies (7 feet high) were firmly fastened to large posts fully 1 foot higher and of quite unnecessary diameter. In the second, large-flowered Chrysanthemums standing in a conservatory had each flower-stalk closely tied to bright yellow Bamboo canes, which separated the florets and overtopped the blooms by many inches. Bamboos and other light-coloured stakes should be painted a dull green, and as soon as the plants have completed their growth should be cut down as low as is consistent with giving secure support. In the garden staking is often left until too late, the result being that the plants present a bunched-up appearance which much detracts from their beauty. Starworts and other tall herbaceous plants should have several thin canes inserted in the clumps while in growth, and loosely looped together with tarred twine, rather than that one large stake should be used, although the latter may easily be added in the midst of the clump when growth is almost finished as an additional security and without being noticeable. Lilies—even the tallest Tiger Lilies 6 feet high—can be easily secured to 4-foot Bamboos inserted 1 foot into the ground. If care is necessary in the staking of border plants, it is even more needful in the case of those grown in pots which are intended to be used for indoor decoration. Freesias are very lovely and lasting in the house, but are often rendered unpleasing in appearance by the nature of their supports. Stiff wire painted to match the colour of the leaves is inconspicuous, and detracts nothing from their graceful contour. In all cases where staking is a necessity a study should be made of how best to create the impression that the plant is growing unsupported, and to render invisible any adventitious aid that may be required.—S. W. F.

**Planting Irises.**—In almost all gardens where cut flowers are needed during May and June the English and Spanish Irises are now regarded as indispensable. Unfortunately, they do no good with me after the first season, although the soil is light and the drainage good. I always get my bulbs in during October, as by

keeping them lose weight and the blooms are in consequence smaller. I plant on both a west and north aspect, and thus prolong the season. Old Mushroom bed manure dug into the borders suits them well, rotten farmyard manure being apt to cause basal rot. Many of the mixed varieties of Spanish Irises as well as the named self-coloured sorts are exceedingly beautiful, rivalling the choicest Orchids. Yell w-coloured flowers being in great request here, Canary Bird is much appreciated. It is of a delicate pale yellow colour. Jupiter, another yellow of a deeper shade, is also very effective. Lady Blanche, fine pure white with orange blotch, forms a fine contrast, and reminds one of some of the choicest Dendrobiums. The English Iris flowers about a fortnight later than the Spanish section, a great advantage where a succession of flowers is wanted. The flowers embrace almost every existing shade of colour, and although they do not travel or last quite so well as the Spanish, they create a brilliant effect in the drawing-room, being best arranged not too thickly with no other foliage but their own. Many of the Irises do best if left undisturbed, but I find the German varieties need dividing about every third year and replanting either on an entirely fresh site or in new soil well manured. The old purple variety can still hold its own, although many of the newer varieties are very delicately and pleasingly marked and mottled. Although thriving in almost any soil, they prefer one retentive of moisture, but not stagnant. The present is a capital time to plant that beautiful little gem *Iris reticulata*. This is exceedingly hardy, blooming in the keenest spring weather, and possessing a fine aroma not unlike Violets. It is most useful for forcing in a gentle warmth, and then comes in well for mixing with small Ferns in fancy baskets in the drawing-room.—J. C.

### PLANTING DAFFODILS.

THE planting of all kinds of Daffodils should now be pushed forward without further delay. No doubt many will have ere this replanted their bulbs, and root-action will have already begun once again. For a large number of kinds I am strongly in favour of early planting, say any time during September. But there are not a few others in this large and varied race of bulbous plants that I feel sure are benefited by a longer season of rest than is usually given them. This prolonged season of rest, however, must not be taken wholly from the one end, but rather be the more consistently divided between early lifting and moderately late planting. All Daffodils should be in the soil by the end of October at the very latest. From a rather close acquaintance with the nursery stocks of such things, I have during a series of years been enabled to watch the behaviour of many kinds that trade requirements have rendered necessary to lift each year. My observations prove that, so far as English or Dutch grown bulbs are concerned, I find no appreciable difference in quality or quantity of bloom between planting in the middle of August or from that time to the middle of October; but if the planting takes place much after that time, there is always a distinct failing off in stature, and more especially in foliage. Indeed, this always ensues, even supposing the bulbs are only a month out of the soil. But it is fortunate also that this falling off in foliage does not represent a proportionate reduction in the flower-stem provided the bulbs are planted by the time stated above. Yet, as proving how this diminution of foliage is affected by later planting, I have found that odd lots left over till nearly Christmas-time will scarcely produce a leaf at all when March comes round; or if any leaves appear it may be a distorted one, and a flower that just wriggles itself out of the bulb somehow. Take the well-known Emperor Daffodil. I have lifted giant bulbs of this kind that carried foliage upwards of 2½ feet high not drawn in the least, but broad and substantial withal. These identical bulbs, duly dried, rested and replanted after six weeks, would only carry foliage about half of the former length, proving in this

particular kind that the period of rest was not helpful. But all our Daffodils are not Emperors, for if they were, annual lifting would not be an absolute necessity. It is just such as this that we may with safety in most soils leave undisturbed for at least three years and more, provided ample room be accorded the bulbs at first. These remarks apply equally to Horsfieldi, Empress, Grandee, princeps, maximus, poeticus, its variety ornatus, and the double albus plenus. Sir Watkin is another that must not be overlooked, and many more from this same group might be named did space permit; in fact, lifting, and annual lifting in particular, with certain kinds must be adopted if we would keep them in health. I have, however, specially named a few good kinds that any amateur may plant fearlessly, and with little trouble after expect a yearly return. One of the slowest to give returns perhaps is maximus, but it is a grand thing and worth waiting for. This kind not only approves of the let-alone system, but it is better with a comparatively holding soil, though well drained, and to this may be added deep planting. Quite recently I was comparing notes as to this kind with Mr. W. B. Latham at Birmingham, only to find his experience much the same as my own, with this addition, that for years it flowered well at the foot of a shrub; but, wishing to increase it, Mr. Latham lifted it and planted the bulbs in better ground. They were not suited by the change, and eventually were replanted in a position similar to the original, with success. Planted in these positions, however, it must be clearly understood that the increase of the bulbs is distinctly slower than in the open garden soil. For instance, the base of a group of Privet, or a hedge of the same, would be a good place for such kinds as cernuus, Ard-Righ, obvallaris, and many others that object to the richer garden soil; indeed, the association of the roots of other plants appears suitable to many Daffodils. In these positions I would recommend deeper planting, say fully 6 inches, unless it be the very small kinds, as Corbularia, triandrus and others, which are better accommodated in other ways.

I am fast getting the Daffodils planted, and as the work proceeds one comes across a stray bulb that has been overlooked in the July lifting. In this way some fine bulbs of the Tenby Daffodil have been upturned, already with a great wiz of new roots fully 6 inches long and literally encircling the base of the bulb. And not only roots, for there is fully an inch of top growth, which is considerable for the time of year. It is a great pleasure to see this sturdy little Daffodil in such good health, though it is one of the most difficult to keep healthy in many gardens, and it can only be done with annual lifting or by planting in positions such as I have suggested above. For the general well-being of this kind, however, I would prefer that the bulbs be quite dormant till the middle of September, and I would place such as Ard-Righ, Golden Spur, and the spurius kinds generally on a similar footing, believing that the enforced rest to this date is rather beneficial than otherwise. The more vigorous kinds, however, may be planted as early as procurable, and the earlier the better. Where space permits I would give plenty of room to free-flowering and robust kinds such as Grandee, princeps, Empress, Horsfieldi, Sir Watkin, Barri conspicuus, and others. The two first named will if good bulbs are planted at first yield three and four flowers each when two years planted without disturbance, and thus seen are simply grand in clumps. Some years ago I planted at the foot of a small Privet hedge half a dozen bulbs of Grandee. With a view to a permanency the bulbs were allowed a patch of 18 inches across. Turning up the soil nearly 2 feet deep, I placed in at a foot deep a rather heavy layer of cow manure, and replacing more soil, finally planted the bulbs at 5 inches deep. All bloomed the next spring, and with increased flowers the year following, I think an average of two flowers each. But at their third flowering, or two and a half years from the date of planting, these six bulbs produced exactly twenty-one grand flowers,

and this is just the way an amateur should plant his bulbs, viz., treat them all specially, and with good sound bulbs they will quickly repay. In the first place, make sure of obtaining the most vigorous kinds, and always include Grandee, for it has a special value by being late flowering. For the more frail and weakly always avoid manure, and even where manure is employed keep it at least 6 inches below the bulbs, and let it be well-rotted material. Where the soil is very heavy and clay-like employ river sand if possible, burnt brick earth, and charcoal dust in plenty. The last may in all heavy soils be freely applied with all kinds, or even in nuts, putting a handful about the bulbs at planting time.

All Daffodils that were lifted either late in June or in July and properly dried should if healthy be now making signs of rooting at the base. Maggot must be always looked for, and thus early is easily detected; bulbs containing such will be soft in the lower part of the neck, and the maggot may be got out with a long pin. If the bulbs have been obtained from a large Daffodil farm, it will be the safest plan to put them in a small linen bag as soon as received, and, including a stone or weight, sink them in a tub of water for twenty-four hours. At the end of that time if any maggots exist they will be emerging from the bulb, and may be destroyed before much damage has been done, but if not captured at planting time the bulbs containing them will assuredly be ruined. H. M.

#### ANNUAL DIANTHUSES.

THE double and single forms of *D. chinensis* show great range of colour, from white, and a very good white too, through pink, lilac, rose, magenta, crimson, &c.; indeed, there is reason to think but few are aware such a range of colours can be found. There are some types handsomely fimbriated, while some are more inclined to the rounded form. Then the plants vary in height. It is particularly to the forms of *D. chinensis* I desire to call attention, and especially for the purpose of advocating autumn sowing. In most gardens there is a cold frame or two to spare, and if the seeds were sown in boxes, and the seedlings pricked out to stand the winter in a bed in a cold frame, or kept in the seed boxes all the winter in a frame, and then transplanted to the open in spring, very fine and vigorous plants would result; they would bloom earlier and much better than those sown in spring often where the plants have to remain to bloom. The sowing of annuals comes at a time when there is an enormous pressure of work in the garden, and they are apt to be neglected, and do too often suffer from neglect. A great deal would be gained by sowing in a gentle heat in spring, transplanting to other boxes, and then planting out after being hardened off. Such plants would be of vigorous growth and well rooted, and would bloom abundantly and finely.

*D. Heddwigi* is the finest form of the annual Indian Pink, and there are some fine varieties of it, such as Brilliant, dark reddish crimson, Eastern Queen, rose, a very pretty variety, and The Bride or Little Gem, white with purple centre, very pretty. The forms of *D. Heddwigi* were originally round-petalled, and later came a fimbriated or lacinated form, which is much admired, and of this type there are also varieties, such as albus, white, and sanguineus, crimson. Double forms of both have also been produced, but to my mind the single forms are the most attractive and the prettiest. A very fine form of the annual Dianthus is that known as imperialis—taller in growth than the Heddwigi type, with smaller and more compactly double flowers, but an excellent type for cutting from. *D. chinensis* has several forms, which are practically perennial in their character. I have some of these in my garden at the present time that came from divided plants last autumn. These have bloomed all the summer, and are still furnishing flowers. I often wonder, now that bunches of annuals are being exhibited at flower shows, that these forms of Dianthus are not more grown for the purpose.

Bunches of Brilliant tell in a stand because of the colour, and in bunches of exhibition annuals there is generally a want of such colours. *Linum grandiflorum rubrum* makes a showy bunch, and so does the crimson *Malope grandiflora*; add to these a crimson annual *Dianthus*, and three good subjects are provided for the purpose.

R. D.

#### THE POET'S NARCISSUS.

REGARDED as a whole, the varieties of *Narcissus poeticus* appear to enjoy a peculiar freedom from disease when compared with the other groups. From time to time I have thought a good deal on the subject, but cannot arrive at any conclusion which appears to be satisfactory generally. A year or two since I stated rather emphatically that I believed a species of mite to be the origin of failure with many kinds, and this view was confirmed by a member of the scientific committee of the R.H.S., who made a careful examination of some apparently healthy bulbs. For years I had known these mites to be present on diseased or partly diseased bulbs, and continuing my search I found them present on fairly healthy bulbs, and eventually on others which outwardly were as healthy as it were possible for them to be. These mites had been frequently noticed on bulbs in advanced stages of decomposition, and for this reason had been regarded as the result and not the cause of the rot. This argument, however, would no longer hold good when their presence on healthy bulbs became an established fact, for not only were they found, but it was further discovered that they were burrowing in subterranean structures. A very singular fact in connection is that they appear to swarm in many of the strongest growing kinds, especially of the trumpet section, yet keeping aloof from the more weakly growing poeticus kinds. This apparent impartiality to *Narcissus poeticus* I can only attribute to something distasteful in the flesh of the bulbs of these kinds, as the mites never attack them, even when such kinds as Ard-Righ, obvallaris and spurius generally are affected in the same garden. In the case of *N. p. ornatus*, it is possible to succeed with the smallest offsets if planted and left alone for a time, while much larger bulbs of other kinds would quickly become a prey to the pest. Even the ordinary double *Telamonius* is not exempt, and especially is this true of some strains. Only this summer an instance of failure came before me of these doubles going wrong, and once in a decline there is little hope left of recovery. But with ornatus you may plant the smallest bulbs and in a year or two grow them into very fine bulbs. Three years ago I planted patches of ornatus in a Gloucestershire garden, where the soil is very heavy and the subsoil is clay. The bulbs were the smallest of offsets, and had been very badly used before they came into my hands. A few weeks ago I had the pleasure of digging up these very bulbs, and after three years in the soil they had made splendid examples, the majority of which will produce three flowers each next spring. Such bulbs as these have of course flowered well for the past two seasons. Instances such as these tend to show the suitability of the Poet's Narciss for almost all soils. A well-known and extensive grower of Narcissi once told me that he regarded "five minutes out of the soil as four minutes too long for ornatus," which was simply a figurative way of saying this kind should not be lifted at all. My own experience fully agrees with this view. Given plenty of room at the original planting it may remain for half a dozen years at least, improving and increasing each year. Amateurs who grow this kind will do well to remember this and plant the bulbs fully 4 inches apart or rather more. This will permit of a good deal of increase, as the bulbs are small and the foliage thin and narrow.

These poeticus varieties are very distinct in their rooting, and appear to keep putting out new roots in succession for months together, as I have found roots of all lengths from June to April. The root fibres also, when lifted from the soil and fully exposed for weeks together, retain

their freshness and vitality. These kinds go to rest much more slowly than many others. Indeed, in some rainy seasons, and where they are not lifted, the foliage of the Poet's Narcissus is quite fresh long after the latest of the Ajax section have gone to rest. The double white-flowered kind, N. p. fl.-pl., or the Gardenia-scented Narcissus, is also worth notice. It has the same peculiarities as the type and the variety ornatus, but in many soils, and especially in southern counties, it is addicted to blindness. I am aware also that the failure is not wholly confined to the south, since inquiries and reports come to hand from a very wide and far-reaching area. This is a most regrettable fact, as in those soils and localities where its flowering may annually be depended upon it would prove a most profitable market kind. Three things are necessary to secure the best results, viz., deep planting, heavy soil, and letting alone for several years. I was interested during the present year to learn from a gentleman who had been taking a holiday in Scotland that quite near to the sea this double form was flowering grandly in large patches. To those whose homes are near the sea-coast this is worth remembering. And, judging from the size of the clumps as described to me, these must have stood for some years in the same position, which in any case I regard as essential. In many English nurseries the bulbs of this are grown to quite a large size, but the percentage of flowers that develop is very small. The Dutch-grown bulbs frequently are much worse, and can never be relied upon for flowering the first year after planting, and only a small proportion blooms the following year. In fact, its general vitality seems much impaired by the drying following the lifting. This matter, however, need not trouble the amateur beyond serving as a warning to lift and replant at lengthened intervals only.

The only other variety of special merit is N. pætarum, a most distinct and charming kind, that is more at home in soils moderately light and well drained than in those of the opposite extreme. This variety should always be included, even in the most select assortment, for the striking colour of the cup is always admired. E. J.

## TREES AND SHRUBS.

### THE VIBURNUMS.

We lately spoke of the value of the wild Guelder Rose (*Viburnum Opulus*) as an ornamental plant. But it is not more beautiful or valuable than many other species of this genus, which is represented in North America by several of the handsomest shrubs of our forest glades.

*VIBURNUM LENTAGO* and *V. FRUNIFOLIUM*, which often grow to the size of small trees, are beautiful with their lustrous leaves, their broad flat clusters of flowers and brilliant fruit, which in ripening changes from green to pink and then to a deep blue, berries of these three colours being often seen together in the same cluster. These are both hardy, fast-growing, vigorous and attractive plants, equally well suited to decorate a lawn or the margin of a wood.

*V. CASSINOIDES* and *V. NIDUM*—the former from northern and the second from southern swamps—are as beautiful in cultivation as any shrubs we are acquainted with. They both have thick opaque lustrous leaves, large clusters of pale yellow flowers and fruit, which in ripening turns bright pink and then deep blue.

*V. DENTATUM* and *V. MOLLIS* are vigorous plants with large, coarsely serrate, lustrous, membranaceous leaves and small bright blue fruit, which does not turn pink in ripening.

*V. ACERIFOLIUM* is a comparatively dwarf shrub with slender branches, three lobed and three-ribbed leaves, in form not unlike those of some varieties of the Scarlet Maple, small clusters of flowers and dark blue or nearly black fruit. From a garden point of view, its greatest value is found

in its neat habit and the purple and dark red colours of its autumn foliage.

*V. PIRESCENS* is a smaller and rarer plant than any of those we have already mentioned. It is distinguished for its excellent habit and the peculiar deep purple colour its leaves assume late in the autumn. This autumn colouring of the leaves is the chief attraction of this *Viburnum*, but this is so great that it should find a place in every collection. The most beautiful, perhaps, of all our *Viburnums*,

*V. LANTANOIDES* (the Hobble-bush), is the only species that it is difficult to accustom to the conditions and surroundings of the garden. Like *Viburnum Opulus*, it produces large marginal, sterile white flowers surrounding the clusters of small fertile blossoms, but these sterile flowers are larger than those of the wild Guelder Rose, and the whole inflorescence is larger and more beautiful. The large rounded leaves of the Hobble-bush are very handsome, and those of no other plant assume a more brilliant scarlet colour in autumn. The fruit when ripening is bright red, but finally turns dark blue-black.

These are all species of Eastern America, common inhabitants of the forest and the borders of swamps, fields and highways; but in the Old World are several *Viburnums* that are hardly less beautiful than our American species.

*VIBURNUM LANTANA* (the Wayfaring Tree), of Europe, is one of the best foreign shrubs that have been transplanted into our shrubberies. The foliage is bold, vigorous and richly coloured; the flowers are produced in profusion, and the fruit, which is black and lustrous when fully ripe, at one time in the summer is bright red. Japan has already contributed to our gardens

*V. TOMENTOSUM*, *V. STEROLDI* and *V. DILATATUM*—all decorative plants of the first class; but in Japan are several other *Viburnums* which will probably prove as desirable ornaments to our gardens as any of these. Among them are

*V. FURCATUM*, the Japanese representative of our Hobble-bush, although a larger and more beautiful plant, common in the forests of Hokkaido, and the scarlet-fruited

*V. WRIGHTII*, a shrub which reminds Americans that their compatriot, Charles Wright, collected plants on the shores of Volcano Bay, as well as on the deserts of our south-western boundary.

Several other Asiatic species not yet introduced into our gardens may be expected to add variety and charm to northern shrubberies; but, considering only the common and well-known species, and taking them altogether, the *Viburnum* form perhaps the most satisfactory group of the deciduous-leaved shrubs of our northern gardens. They are perfectly hardy, easily raised from seed, easily transplanted, exceptionally free from disease and the attacks of insects, grow rapidly into shapely bushes, producing their flowers and fruit profusely, and in autumn the foliage of several species assumes brilliant colours. In planting a garden or park in the Northern States, if our choice of material was confined to the species of a single genus, we should not hesitate to select the *Viburnums*.—*Garden and Forest*.

**Rhus Michauxi.**—This extremely rare shrub was, according to the *Garden and Forest*, discovered at the end of the last century by the French botanist Michaux in western North Carolina, in what is now Mecklenburg County. Later it was found by Lyon in North Carolina in fruit, and in flower by Boikin, and by Le Conte in Georgia; and recently it has been rediscovered by Mr. W. W. Ashe, of the Geological Survey of North Carolina, at Farmington, Davie County, in western North Carolina; and by Mr. F. B. Boynton and Mr. E. L. Olmsted, Jr., it was introduced last summer into Mr. Vanderbilt's arboretum at Biltmore, whence it has been sent to the Arnold Arboretum. By Messrs. Boynton and Olmsted, who found three clumps of this plant with ripe

fruit, *Rhus Michauxi* is described as a shrub with erect stems from 1 foot to 3 feet in height, spreading extensively by underground stolons. The leaves are deciduous, oval or oblong, dark dull green on the upper surface, pale on the lower surface, about 2½ inches long and 1½ inches wide. The panicles of flowers, which were collected by both Boikin and Le Conte, are terminal, about 6 inches long and nearly 3 inches broad. The fruit is nearly globose, about an eighth of an inch in diameter, bright scarlet, and clothed with close silky pubescence. The juices of *Rhus Michauxi* turn black in drying, like those of several of the poisonous species of *Rhus*, and Pursh, on the testimony of Lyon, who suffered seriously from it, and Torrey and Gray describe the plant as exceedingly poisonous, while Curtis denies its poisonous properties. From my limited experience with a partly dried specimen I am inclined to believe that it is the most poisonous of the North American species.

## GARDEN FLORA.

### PLATE 1038.

#### GOLDEN-FLOWERED RICHARDIAS.

(WITH A COLOURED PLATE OF *R. PENTLANDI*.)

It is now half a dozen years since the first of these golden-flowered *Richardias*, or *Callas*, as they are generally called, bloomed in this country, but it was not seen in public till a year later, when under the name of *R. Elliottiana* it was in May, 1890, awarded a first-class certificate by the Royal Horticultural Society. Of this variety (*Elliottiana*) a coloured plate was given in *THE GARDEN*, November 24, last year. *Richardia Pentlandi*, the form herein figured, is of more recent introduction, and was awarded a certificate by the R.H.S. two years later, viz., June, 1890. The leaves of this are as large as those of the common *R. æthiopia*, but thicker in texture and of a deeper green. The leaf-stalk is very different, being in *R. Pentlandi* suffused with red and mottled with green, brown, and white, after the manner of some of the *Alocasias*. The colour of the flower is a bright golden yellow, with a small blotch of crimson at the base of the interior. Both *R. Pentlandi* and *R. Elliottiana* are deciduous, and grow rapidly when they start in the spring, that is, if they are kept in a structure at an intermediate temperature or even at the cool end of the stove, for they both require more heat than is usually given to *Richardias*. This peculiarity is well explained by the conditions under which they grow naturally, for in the *Gardeners' Chronicle* for June 22 of the present year, Mr. Ayres, the well-known nurseryman of Cape Town, under the heading of "*Richardia Pentlandi* in its Native Habitat," writes thus:—

As I have recently introduced this variety into England, it may be of interest to those who possess plants to know a little about the manner in which it grows in the wild state. This variety is not found growing, like the old *R. æthiopia*, in large clumps in low-lying, swampy land, but occurs only in rocky mountainous districts as isolated specimens, and always close to large boulders. The tubers are always from 9 inches to 18 inches (more often the latter) deep in the soil, and whenever it is possible for them to do so, they get underneath the boulders. The soil is mostly a good loam, with a surfacing of leaf-mould and rotten wood. The only place in which I have found them is in what is known as the Low or Fever Country, which has a very hot and rainy

\* Drawn for *THE GARDEN* by E. Carter in the Royal Gardens, Kew, May 16, 1894. Lithographed and printed by Guillaume Severeyns.

summer and a very mild, dry winter. This tuber, like that of the *Caladium*, loses all its fibrous roots annually.

*R. Pentlandi* is still an expensive plant to purchase, for though it can be readily increased, yet there is a considerable demand for it. However, now that its value is so generally recognised, it is likely to be well sought after in its native habitats, and if we have many such importations as the one sold last April at the London auction rooms, when 500 tubers were disposed of, it should soon become far more common. Though I have not seen any of this importation in flower, yet many growing plants have come under my notice, and as far as one can judge in the absence of blossoms, there is little, if any, doubt that the bulk of them consist of *R. Pentlandi*, with an occasional *R. Elliottiana* amongst them. It now only remains to be added that *R. Pentlandi* was first flowered by Mr. R. Whyte, *Pentland House*, Lee, hence the specific name. *R. Elliottiana*, the other golden-flowered variety, has many points in common with the preceding; its leaf-stalks are mottled in much the same way, but the blade of the leaf is marked with a few white translucent spots, as in the older and better-known *R. alba maculata*. The flower of *R. Pentlandi* is of a rich golden, almost orange, yellow, but before decaying it turns greenish.

These two golden-flowered *Richardias* approach each other so closely, that it is difficult to say which is the more beautiful. The flowers of both are as large as those of the common white *R. aethiopica*, which accounts for their popularity, as small yellow, or rather yellowish-flowered species were known previously. *R. hastata*, which was introduced from Natal in 1857, is one of these, but its spathes are small and of a dull greenish yellow tint. *R. melanoleuca* and *R. albo-maculata*, with *M. Deuil's R. aurita* (said to be a hybrid between *R. hastata* and *R. albo-maculata*) complete the list of *Richardias* with yellowish blossoms.

All the species of *Richardia* were so exhaustively dealt with in *THE GARDEN*, November 24, 1894 (when the coloured plate of *R. Elliottiana* was issued), that reference to the article in question will set at rest any doubtful point that may arise. H. P.

## THE WEEK'S WORK.

### HARDY FRUITS.

**THE FRUIT STORE.**—The work in this department will have been delayed later than usual on account of the late ripening of some varieties. Apple trees having in many localities been heavily cropped with fruit, more time than usual will have been taken in storing the crop. Many of the earliest varieties will now be out of the way and thus make room for later kinds. I fear fruit will not keep so well as usual, as the earlier kinds have decayed badly, many maturing before their time, doubtless owing to the drought and heat earlier in the season. It is advisable at this date to frequently look over the stored fruit, removing those decaying, as the least contact with sound fruit soon spoils the latter. Many shifts have to be made in storing when there is a heavy crop, but the latest kinds should get a suitable place, as though less showy than the earlier or mid-season varieties, they are very welcome at a time fruit of any kind is scarce. Dessert Apples of such kinds as *Egremont* and other *Russets*, the small *Nonpareils*, *Cox's Orange*, and similar good varieties should be as little exposed as possible to fluctuations of any kind, and if kept cool will keep much longer. The later cooking kinds may often be stored away from the kinds required for

use up to Christmas. Any place frost-proof will be preferable to a warm room or close fruit store. In all cases it is well to store the late kinds as far apart from early or decaying kinds as possible. Some years ago I used to store all my late fruits, such as Northern Greening, Alfriston, and *Hanwell Souring*, in a dry, disused ice store, and never was short of good fruit. Pears are often gathered too early, and are soon spoiled after storing. Such kinds as *Winter Nellis*, *Josephine de Malines*, *Easter Beurré*, *Nouvelle Fulvie*, *Beurré Rance*, *Olivier des Serres*, and *Bergamote d'Esperen* all require late gathering and cool storage when placed indoors, and as they ripen brought into the ordinary store at the warmest end. In storing fruit of any kind it is well to place on clean wood racks on clean paper. Apples may be placed thicker than Pears and keep well in heaps, but straw should not be used, as it soon gets mouldy and causes the fruit to get tainted.

**THE PLANTING SEASON.**—Though, so far, we have had but slight frosts, making the planting season later than usual on account of the leaves remaining longer on the trees, it is advisable to select early and plant this month if possible. I am a great advocate of early planting, especially in light gravelly soils, as the trees suffer less the following summer, and in clay land one can with advantage add to the ordinary soil and make it porous. One thing still lacking is moisture. Although in many places there have been heavy rainfalls, I find the soil very dry underneath large trees on walls and in sheltered places, so that in planting at this date it may be advisable to prepare the sites and allow them to be exposed for a short time, well saturating if found dry. In case the ground is not fit for the reception of the trees at the time they are received, they should be laid in carefully after unpacking, and may then be planted as soon afterwards as possible. If the weather is frosty it is not advisable to remove the packing, but to place the trees under cover or in a frost-proof building, this being preferable to placing in the soil in a frozen state. The roots of newly-lifted trees should not be exposed a moment longer than is necessary, as winds soon dry the fine fibrous roots. If received in a dry state it is well to immerse for a time in a tank before planting, and to syringe tender trees such as Peaches and Nectarines, as the wood of these soon shrivels if at all dry or much exposed. In planting, the grower must take into consideration the kind of soil, as newly-dug clay soil holds the moisture too freely and needs aid in the way of lighter materials to make it porous. The value of drainage must not be overlooked; plenty of brick rubble or, failing this, clinkers will do much good. I have seen many failures owing to want of drainage. Apricots, Peaches, and Nectarines delight in a well-drained soil, and though they require water in abundance from June to the end of August, they do not thrive if the water is stagnant at the roots. The holes for the trees should be at least 3 feet deep for young trees, and the drainage should be 2 feet or more below the surface, ashes or clinkers being freely used in heavy clay land. A hard trodden layer of ashes will check downward roots and give the trees the necessary drainage. Compost for planting may be prepared by mixing with the top soil of the border burnt garden refuse, wood ashes, and fine mortar rubble (road scrapings are excellent). Of course, where turf can be procured there is no better compost for young trees, but it is not always available. In planting in light soil, or that resting on gravel, the addition of heavy loam will be advantageous, and in some soils deficient of lime, an important factor for fruit trees, chalk and mortar rubble are valuable additions. It is well to plant young trees rather high, as with repeated mulchings, feeding, and top-dressing they will be quite deep enough, and high planting will save early root-pruning. Plant firmly, well spreading out the fibrous roots, packing underneath with good soil. Cut away any bruised or broken roots. With each layer of soil see that the fine roots are not twisted,

but spread out evenly. Manure can be supplied from the surface in the shape of a mulch or winter dressing, also in the early summer, as a protection from drought. In heavy land, raised borders are advised for stone fruits. I find the trees do much better raised a few inches above the ordinary garden level. In lighter soils on gravel I do not advise the trees being planted above the ordinary ground level.

**STOCKS FOR FRUIT TREES.**—I am aware the question of stock on which the trees are worked is not always taken into account. It is important, as the growth is so much influenced by the stock. For instance, if we take the *Paradise* stock for dwarf trees, such as bushes, pyramids or cordon Apples, it should be borne in mind there is more than one kind of *Paradise*. I prefer the broad-leaved one of the many varieties on account of its greater vigour. Some kinds do much better on the *Crab*. Pears, like Apples, require consideration. The *Quince* stock is now much employed for dwarf trees, such as cordons, dwarfs, espaliers and pyramids, giving larger fruits and in quantity. For tall trees, standards, and in light gravel or chalk soils the *Pear* stock is selected. It is well when getting new varieties or forming new fruit plantations to consider the soil and the stock the trees are on.

**FRUIT-TREE LIFTING.**—I noted the importance of this work a few weeks ago, and will now only briefly allude to the subject, as the lifting of some trees will have been delayed, owing to fruits hanging or the leaves being green; there should be no further delay. This work is much best done as early in the autumn as possible. In some places the subsoil will be found quite dry. In such cases it is well to remove a portion of the surface soil and saturate with water a short time before lifting. Stone fruits are much improved by lifting, as stone-splitting, canker, mildew and barrenness show that the roots are not feeding upon the surface food given and need raising. Large trees that produce coarse wood may require two seasons to bring them round, doing one half of the tree each year. Trees growing into each other may with advantage get more space. If on walls there need be no loss of a crop by careful lifting at this season. Apricots and Cherries should get the earliest attention.

G. WYTHES.

### KITCHEN GARDEN.

**GENERAL WORK.**—This embraces a good deal at this period of the year, and in large establishments means a lot of labour, as the time left for carrying it out is but limited, wet and unfavourable weather being liable to set in at any moment. The *Pea* season being now over, all haulm and stakes must be cleared from the ground, the latter being tied up into bundles according to their length and stood erect in some out-of-the-way corner. As a rule, unless composed of *Ash* or *Hornbeam*, the bottoms decay the first season, and shortening has to be practised before using them again. Stakes that have been used for 4-foot *Peas* will come in useful next spring after shortening for such early varieties as *William Hurst*, *Chelsea Gem*, or indeed any of the favourite first early sorts. The same remarks apply to *Bean* stakes; and although these, by reason of being stouter at the base, often do a second season without shortening, any that have to be reduced will do next year for runners that are pinched instead of being allowed to go their full height, or even for supporting the newer climbing *French Beans*. Any stems of *Autumn Giant* or *Walcheren Cauliflower* from which the heads have been cut should be pulled up and thrown away at once, as damp, foggy weather quickly induces decay and a most offensive smell. This is especially needful where the mansion is close to the garden. In some places manure is difficult to obtain in sufficient quantities, and the most has to be made of opportunities. Where it consists entirely of straw litter from the stables, it must be prepared before being wheeled into the garden. Turn it over at intervals of a fortnight, well soaking it with water as the work of turning proceeds; this will induce

decay. Such manure is far better for working into stiff retentive soils than thoroughly decomposed manure, as it lasts longer and tends to keep the soil in an open condition. For crops which do not rob the soil of much of its virtue, old Mushroom manure is not to be despised; indeed, if a percentage of some good fertiliser is added to it, the best of crops may be secured. A composition which is of immense benefit to old gardens where nothing but ordinary manure has been used for many years consists in the prunings of fruit trees, old vegetable refuse, the clearings of the potting sheds and similar materials, these being first burned and having added to them a sixth part of lime and the soil from old Vine or Peach borders. This makes a thorough change and its value is seen in the vigorous crops it produces the first season. Now is a good time to rectify all faulty drains, renew gravel walks and straighten edging tiles, which sometimes get out of place by the pressure from the garden roller or the foundation sinking. It is not wise to postpone this kind of work until frost and wet render the soil and gravel soft and sticky.

**RIDGING AND TRENCHING.**—It is useless to talk about this in some gardens at this time of year, as their small size renders it necessary to crop every inch in order to eke out the supply till spring; in fact, lack of space and convenience often make the work of calculating and planning for future crops more irksome than actually growing the crops themselves. However, as the various plots for different kinds of vegetables for next spring have in most gardens been decided upon, any vacant piece of ground, however small, should be got in readiness as opportunity offers, there being always more than enough pressing work in February and March, especially when a sharp winter suspends outdoor labour. Let the ground for Carrots be deeply cultivated, that is to say, where there is a sufficient depth of soil, but do not upon any account trench for the sake of trenching; rather keep what good soil there is in good heart and grow the intermediate forms of Carrot. The present is a good time for working in a good quantity of gaslime, as sufficient time will elapse between now and sowing for the harmful properties to vanish. This ingredient is undoubtedly the best eradicator of that worst of all Carrot pests, wireworm. Ground that has been dug two spits deep within the last three years will be best treated by merely ridging up the top spit. Mark out the ground at both ends, allowing spaces about 15 inches wide, after which fix the line and make a cavity the depth of the spade the whole length of the plot, and finally ridge up. As manure is not so easily buried as in the case of ordinary digging, the best way is to use none when ridging, and to use a fertiliser when the ground is again levelled down in spring. Ridging is more necessary in strong soil than on light, but experience proves that it is highly beneficial to both by pulverising and sweetening it. In preparing borders for early Potatoes, or for main crops of Carrots, Beetroot, or Parsnips, do not dig in manure, as this induces gross haulm at the expense of the tubers in the first-named vegetable, and coarse forked roots in the three latter. In cases, however, where these subjects have to be grown on the same ground two years running, which ought always to be avoided where possible, a little manure must of course be added.

**LATE CELERY.**—The latest-planted rows intended for blanching must now receive the final earthing up. If other work is pressing, it may be postponed on very light, well-drained soils for a fortnight longer. On strong soils, if the work is not done in fine, comparatively dry weather, repeated rains get the soil into a sticky condition, so that earthing is carried out under great disadvantages. Choose if possible a dry windy day for earthing up these late rows, as they very often prove of more service than those blanched earlier, so far as keeping is concerned, as growth being slower and longer exposed to winds and the early autumn frosts, the stems stand the winter far better and do not rot in wet springs. Very late rows in shallow trenches will take no harm if not

earthed up, so long as the tops are protected with Bracken or straw, should frost of intense severity set in. Should wintry weather prevail during the early part of November, it will be the wisest plan to take up a few score heads and lay them in soil in the root shed rather than have to use a pickaxe to remove the ridge soil and to thaw the Celery afterwards.

**WINTER TOMATOES.**—The present time is rather a critical one with the main batch of plants for mid-winter supplies, and without a good deal of attention the blooms are likely to fall off, not being properly fertilised. Just at this period many cultural errors are made, one of the most common being maintaining too high a temperature, especially at night. This produces a soft growth, the blossoms of which have not properly developed organs, and they either fail to set at all, or the fruit is malformed and inferior. At the same time the air of the house must be of a warm and rather dry character, say from 55° to 60° on warm nights, the former figure being sufficient during frost. Very little damping down will be needed, the moisture arising from the surface of the pots being sufficient to support both foliage and fruit. Admit air on all favourable days, close early, and let all watering and washing out be done early in the forenoon. Refrain from the use of stimulants, as the more slender and hard the stems are the better in every way. If plants have been raised for an extra early crop of fruit in spring, they will now need very careful treatment. While a strong growth is not advisable the plants must not be allowed to become pot-bound or starved. Plants in 4½-inch pots may when fairly filled with roots be shifted into 6-inch ones, the compost consisting of good holding loam and a little bone meal, ramming firmly and placing them near the glass in a temperature of 55°. These pots will carry them on to the new year, when they must be shifted into those 10 inches in diameter to fruit in.

**WINTER SPINACH.**—This important vegetable is a failure in many gardens this year, owing to the excessive drought of August and September. Especially is this so on light, porous soils. Where a good plant has been secured it will be worth almost any amount of trouble and care. If a good sprinkling of soot is given between the rows and the Dutch hoe afterwards used, it will not only assist growth, but also keep off the attacks of slugs. For a sowing in February next, the sooner the ground is got in readiness the better. Wireworm-infested soil should be treated exactly as advised for Carrots, except that a good quantity of manure must be dug in, as Spinach enjoys a rich and sustaining soil. Tolerably close pickings from beds now yielding are advisable, as they encourage the formation of young leaves during the early part of the winter. J. CRAWFORD.

## KITCHEN GARDEN.

### AUTUMN SUPPLY OF CAULIFLOWERS.

CAULIFLOWERS are not valued when we have an ample supply of Peas, Beans, and what may be termed other choice vegetables, neither are they palatable in hot weather. I think the value of this vegetable lies in its nice sized or even small heads, with white close curd and a large portion well covered by protecting leafage. This adds to flavour, an important point, as strongly flavoured vegetables are not inviting. I am writing from a private gardener's view. My comments as to size would not be applicable for market, but even with market supplies the tendency to huge heads is not so great as a few years ago. Cauliflower and Broccoli are so similar in appearance that the difference is scarcely perceptible. Of late many varieties have been added to both, and there is a wealth of material to select from. Though there have been many additions to both, the improvement is greater among the Cauliflowers, our winters being too severe for the Broccoli. So far we have not obtained what can be classed a hardy

Broccoli, though doubtless considerable advance has been made in habit, and by this means the plants are better able to battle against our variable climate. Forty years ago there was no lack of varieties; no less than twenty-eight kinds are given as desirable and some of these are yet classed as standard varieties. The well-known Veitch's Autumn Giant heads the list for usefulness at this season, but it can be grown too coarse. Many advise sowing in heat early in the year, but it is not necessary if quality and not mere size is the chief consideration. If sown too early the heads in such seasons as this and 1893 are fit for use at the end of August and through September, when I do not think Cauliflowers are wanted. Of late years I have contrived to have the supply at this season, and it then fills up the void and makes good the loss of Marrows, Beans and Peas. There are also other advantages in having the supply at the end of September and through October. By sowing in the open in March, even in late localities, good material is secured by the date named if the plants are not allowed to become crowded in the seed beds, given ample space in their growing quarters and planted on an open exposed border. In light warm soils it is advisable to make two sowings, one early in March, another a month or so later; these will give a long autumn supply and provide heads till the early Broccoli turns in. I admit in cold districts an early sowing may be necessary. Many growers sow this useful variety in August for their early spring supplies, and it does grandly in dry seasons, standing when others bolt. In many country districts large quantities of this variety are grown for pickling, and many growers who sow for early supplies find it advantageous to tie up the heads, as when exposed in sunny weather they soon assume a pink tinge and are less valuable.

The Autumn Protecting Broccoli is a great gain and invaluable to the private grower, as he can keep up the supply without difficulty till Christmas. I am aware we cannot always depend upon open-air supplies until that date, but this variety lifts so well, and with the rudest shelter will give heads of nice size and quality. I have found unheated frames, turf pits, and even cellars most serviceable to eke out the supply, and have, in country districts with a large and varied supply to maintain through what is termed the hunting and shooting season, found this Broccoli more appreciated than at any other time. Those who have not storage room, as advised above, may make shift, and place in vineries, Peach houses or casks, or even sheds. Wherever stored, excess of moisture should be guarded against and all decaying leaves removed. The Protecting Broccoli sown in April and again in May will give a supply from October to January, and for December supplies late May sowings will be best. The old Cape Broccoli is still reliable for autumn use. At one time there were numerous varieties, the Purple being much grown, but these are none too hardy, and in my opinion are not so useful as the varieties named above. Snow's Winter White Broccoli for late autumn or early winter supplies cannot be relied upon like the Self-Protecting. At times well-grown plants fail to turn in, and if lifted before the heads are formed they do not make the progress one would desire.

G. WYTHES.

**Young Carrots in winter.**—Those who have a varied supply of vegetables to keep up through the winter will find young Carrots most acceptable. To get Carrots at the season named is not difficult, and they do not require much protection. I have used Bracken cut when green and dried in the sun. If cut when ripe, it soon breaks and decays. Of course, frames are preferable if they can be spared, and movable ones are most useful. I usually sow in August for the winter supply, sowing thinly on rich soil made firm. The season of growth being somewhat limited, the roots require every attention at the start. There are several good varieties for winter use, the Parisian Forcing doing well sown at the time named.

This is a small stump-rooted variety, with small top and almost round, of a bright red colour, and excellent quality. Early Nantes, a larger root, is superior to the Parisian Forcing. This variety is very sweet, having but little core, and is of fine quality. Sutton's Inimitable Forcing is likewise good, the roots small, globe-shaped, and the quality all that can be desired. It soon turns in, and keeps sound a long time. For winter use these three are all good, and when glass can be spared or even rough shelter, such as turf pits or thatched hurdles, given in severe weather, young Carrots may be had from November till April.—G. WYTHES.

**Potato Renown.**—This is really one of the very best of the newly-introduced round Potatoes I know of. Were its qualities more widely known it would, I feel sure, be largely grown in fields for market as well as for private use. In shape it resembles that good old Potato, Schoolmaster, but it is even rounder and with fewer eyes. It crops wonderfully evenly, there being very few small tubers, and, so far as my experience of three seasons goes, it resists disease better than most varieties. The quality when cooked leaves nothing to be desired, and it keeps sound and good right into the spring months. Let those who are thinking of trying a fresh variety next year give Renown a trial. They will not, I think, be disappointed.—J. C.

**A variegated Cabbage** that we saw in the nurseries at Hexham shows a curious, and by no means ugly freak, for it is certainly as handsome in distinctive well-defined colour as are the variegated Kales. The seed when sown was said to be the result of crossing the red pickling with the ordinary green-leaved Cabbage, and there is proof of this in the reddish tint that pervades a few of the plants. Only one, however, is variegated, and this has white leaf veins on a light green ground, and a broad, regularly defined margin of pale yellow flushed with red, and quite an inch in width all round the leaf.

**Late Potatoes growing out.**—There is much complaint hereabouts among growers respecting the secondary growth in the tubers of late Potatoes, Magnum Bonum, The Bruce and Reading Giant being the greatest offenders. In many tubers the first growth has commenced to decay and the second is soft and not matured. That there will be a good deal of complaint respecting the cooking qualities later on may be taken for granted, and there must be a good deal of loss in decay and waste. The later growth in the tuber was deprived of its chance of maturing fully in the loss of the foliage and stalks, which seemed to give out very quickly. Many resolutions will be made in consequence of this failing, the offending ones being discarded and earlier maturing sorts substituted.—W. S., *Trowbridge*.

**Secondary growth in Peas.**—During September I was able to gather a good many dishes from rows which had given their crop much earlier in the summer, and naturally these were very acceptable when a larger demand than usual has to be met for the shooting season. In the ordinary course of events these Peas should have been cleared away, but noticing a new growth appearing a few days after the spell of summer drought had been broken by rain, they were intentionally left for the supply of some autumnal dishes, because those sown for successional use were badly crippled by mildew and the crop promised to be light.—W. S.

**Rochford Market Cucumber.**—I quite agree with the remarks of "G. W. S." (p. 258) with regard to the value of the above Cucumber, which I have grown for some years. By selection I have obtained a capital strain of it, which for productiveness and general utility will take a good deal of beating. For market use I suppose near London that no kind is grown so extensively as the above, and it is equally valuable for private work. The fruit is of such uniform size, combined with excellent colour, a strong point in the Rochford, that it is sure to take the eye of the buyer. It possesses general rotundity from the

handle, which is exceedingly short and blunt, to the other extreme. Another decided advantage is that it remains fresh and plump much longer than any Cucumber I know. I hardly agree with "G. W. S." in saying "it is somewhat like Telegraph," for I regard it as most distinct from the latter. Telegraph always has a much longer handle, which runs up to a shoulder, and from this tapers to the point. It is also much paler in the skin, and when cut quickly becomes elastic. These points are against it on the market when in competition with the Rochford. If the latter is needed for exhibition it will vie with any; indeed I have grown it this season 23 inches long, straight as a dart, and that without any special care beyond the usual cultural routine. I formerly grew two houses of Telegraph (which, by the way, I knew prior to its being named) and several others of Rochford, but in the flats, as packed for market, the former spoiled the prime quality and colour of the latter; so much so, that I kept it separate, and eventually discarded it. I have this season a grand lot of seed fruits of Rochford, many of which are of large size.—E. J.

**Cauliflower Eclipse.**—A note of praise for this Cauliflower recently appeared in THE GARDEN, and it certainly deserves it. It is now a good many years since Eclipse was introduced, and it is rather strange that it is not more universally grown, as for a Cauliflower to follow Early London, Walcheren and Pearl I know of none more suitable. It has a grand constitution and is not addicted to premature buttoning. If sown in autumn and protected in frames through the winter it will furnish good-sized white heads during July. If sown in spring in a cold frame or on a warm border, it comes to maturity at the same time as Autumn Giant, but does not grow to such a large size even on rich ground, this being an advantage rather than otherwise. Eclipse, being hardier than either Walcheren or Early London, is a very good sort for those who have no convenience for protection in winter. If sown on a warm border and covered in sharp weather with leaves or Bracken, the plants will survive if the winter is not too severe.—J. C.

**Pickling Cabbages.**—At page 259 Mr. Wythes speaks highly of the dwarf blood-red form of pickling Cabbage, and doubtless it is hard to beat. Another good and reliable form is Stocking's Giant Red. This is very quick in growth and good in colour, and if sown in spring and grown on without any check, will produce fine heads by autumn. Personally, I am not so much in favour of monstrous Cabbages for pickling, as they are invariably much coarser than medium-sized heads, the quality also being inferior. Plants raised in spring can be planted closely together, and they do not impoverish the soil to such an extent as the extra large Cabbages, which often draw all the stamina from the plot on which they are grown. Another advantage of spring-raised plants is that they are not so liable to split and rot as large coarse ones.—C. H. N.

**Beans for seed.**—Some time ago I advised saving seed both of the runner and dwarf varieties of Beans from second early sowings, as later rows did not, as a rule, ripen up the seed satisfactorily. The pods should now be collected and placed in flat baskets or boxes and removed to a dry, airy vinery or greenhouse, exposing them fully to the sun and turning them each day to hasten maturity. When thoroughly ripe, shell and store the seeds in muslin or even paper bags, and keep in a perfectly dry cool place. The least damp is ruinous to Bean seed.—J. C.

**Tomato cuttings.**—Where plants raised from cuttings are relied on for supplying ripe fruit, say in April, they should now be taken off. This, however, must not be thought of if the parent plants have been affected in the least degree by disease, or the probability is that the young stock will show it early in spring. Put five or six cuttings into a 4½-inch pot and place in gentle warmth, dewing them over with the syringe early on sunny afternoons for a time. When rooted place on a shelf near the glass in a temperature of 50° to

winter them. In January these may again be topped and fresh cuttings inserted. To secure extra early fruit place the cuttings singly into small pots, and in spring repot, removing some of the lower leaves from the stems and coiling them round the pots. In this way additional roots are produced from the stems and the plants thereby strengthened. A 10-inch pot is large enough to fruit them in.

**Small salad.**—As the majority of the larger leaved Cresses will now be past, there will be an increased demand for Mustard and Cress, which must be brought on regularly in a gentle warmth. Sow weekly or once in ten days in shallow boxes, rough leaves being placed in the bottom and a fair surfacing of friable soil added, this being well firmed and the seed sown. Press this in with a piece of slate or board, and cover the boxes with stout brown paper or slates until the seedlings are an inch high. When almost ready for use remove to a cool house and give little water, as mould is very liable to attack it at this season.—C. H.

**Shallots.**—I am pleased to note that "A. D." (p. 216) prefers the true Shallot to the coarser red or large Jersey variety. "A. D.'s" remarks are opportune as regards shows, as I recently was judging a class for Shallots, and out of some twenty odd dishes there were only five of the true old variety, three of these excellent, but, of course, lacking the size of the Jersey variety. I knew which was best as regards keeping and for cooking or preserving, so awarded the prizes accordingly. I found that the judges the previous year had given all the awards to the Jersey, and the result was visible, as nearly all the exhibitors had gone in for this variety. When mere size is recognised by the judges at shows held under the auspices of the Royal Horticultural Society, we must do what we can to combat what appears to me to be a great evil.—S. H.

**French Bean Sutton's Dwarf Forcing.**—The season of forcing will soon come round, and it may be well to note the value of the above. I was much pleased with it last season. It is a great advance on some of the older kinds, being earlier and one of the most productive pot Beans I have grown. Good French Beans are valuable early in the year, and those who force hard I would ask to give a trial to the above. Sown at the end of the year, good dishes will be secured the second month in the year and in quantity. I have not grown it in the open or with protection for first crop, relying upon Mohawk and a seedling from the latter, but I should say Sutton's Forcing would do well and prove an acquisition for planting out when raised under glass. Being very dwarf it is readily protected, and when cooked is all that can be desired as regards flavour. I intend to give it a trial for first crop in the open, as Beans early in June are none too plentiful.—G. WYTHES.

**Winter Tomatoes.**—The demand for Tomatoes seems to be less during the mid-winter months than was formerly the case. About six or seven years ago I could sell any quantity early in the new year at 2s. 6d. per lb., but, so far as I can learn, no one makes such prices at that season now, and even if they could be obtained, they do not pay, as the expenses are greater than the receipts. It is different in a private place where a few Tomatoes are required all the year round and the cost of production is not an object. Many small growers of Cucumbers are rooting out their plants, or have done so already, and some are filling their houses with large Tomato plants, thinking they will make a good thing out of them.—W. G. C.

**The Globe Artichoke.**—This delicious and favourite vegetable is easily grown. I think I have had the finest and most prolific lot of Globe Artichokes this year that I ever remember. As usual, last November I placed burnt ashes of garden refuse round the roots and over them light stable litter, which, on removal as usual in the spring, I thought had not sufficiently protected the plants against our unusual severe winter, for not a vestige of life was visible. However, after

the first showers of rain I applied some weak liquid manure, which speedily brought vegetation to light; and from the end of June (when I discontinued cutting Asparagus) until now, I have had an exceedingly heavy and fine crop, which will probably continue, as it did last year, till the middle of November, when the same process for next year will be adopted. The Globe Artichoke requires good feeding and also a strong soil, but the crowns should not be covered with heavy manure during winter, as this causes them to rot, especially with snow. Very light litter I have found to be the best protector. The prickly Globe Artichoke is the hardier and more prolific, but its flavour is far inferior to that of the smooth kind. The plants will last many years without removal if fairly well treated.—GWENT.

**Large Beetroot.**—These roots, as far as one can judge in a limited area, are not good this season, being overgrown and somewhat coarse. I do not like coarse roots, and would not advise storing them for late use. Place them on one side for early supplies, as they are much best used as soon as possible. It may be thought much of this coarseness is owing to early sowing, rich soil, or large kinds, but such is not the case with me. I did not sow till the first week in May, and in land that had not been recently manured. I think the season is to blame, for the first three months the roots made little progress. Then we had heavy rains, and with the earth in a warm state growth was rapid, and to this I attribute the overgrown roots. Fortunately, I rely upon the small Dell's Crimson for late supplies, and this is much larger than usual, but it will be acceptable and keep till the Turnip-rooted comes in. A late sowing of Turnip-rooted is useless, owing to the size of the roots. I find they also lack colour and are of poor quality when cooked.—G. W. S.

## STOVE AND GREENHOUSE.

### PLUMBAGO CAPENSIS.

AMONG the many climbing or shrubby plants that are used to adorn the pillars and rafters of glasshouses few are more beautiful than this *Plumbago*, of which an excellent example is shown in the accompanying illustration. It is as well adapted for the little greenhouse of an amateur as it is for a spacious conservatory, as when once established in its allotted space it will afterwards bear restriction with impunity. For pillars, such as that here shown, it is by far the best to plant out the specimen in a little border of prepared soil, consisting of two parts of sandy loam to one of peat made firm, and when in active growth and flower a watering once a week with manure water will be of assistance. In winter the plants can be pruned hard back to the leading shoots, and little water is needed during that season. In its particular shade of blue there are very few flowers that resemble this *Plumbago*. A coloured plate of it and its pure white variety was given in *THE GARDEN* of April 21, 1888.

Mr. Chalmers, The Chestnuts, Cranbrook Road, Ilford, in whose garden the photograph from which the illustration was made was taken by Mr. E. Wright, of Forest Gate, writing of the plant says:—

The plant, growing in a cool part of the greenhouse, was literally covered with flowers. About July it produced a grand mass of bloom from top to bottom. *P. capensis* alba mixed with the type makes a splendid combination.

*Dracæna Massangeana* is a very handsome greenhouse plant that we admired as grown under glass in Messrs. Fell's nursery at Hexham. It has beautiful leaves, each 16 inches long, 4 inches wide,

and they arch gracefully at their tips. They are of a deep glossy green colour chiefly, as this shade forms two broad margins to the leaf, whilst down the centre are several strips of light yellow, which extend unbroken the full length of the leaf. A fact that adds to its decorative value is that it can be raised from seed and comes quite true.

**Carnation Daybreak.**—From the glowing description which accompanied the advent of this

mer. But now that the great heat has passed the flowers are assuming more colour, and the centre of the blossoms is a light rosy pink hue, gradually fading to a lighter shade at the extremities of the petals. It is, therefore, evidently not a good colour to stand strong sunlight. The flowers are of fairly good size and borne on stout stems, but so far as can be seen at present, it is the reverse of free flowering. The habit is vigorous—in fact, a little too much so, for

*Plumbago capensis.* From a photograph sent by Mr. C. Chalmers, The Chestnuts, Ilford, E.

American variety a couple of seasons ago I had both looked for and hoped that we had something good to add to the list of really "pink" flowers. I was very much disappointed when the first flower opened to find it of a poor, washed-out colour, neither white nor blush, and most certainly not pink, and, worst of all, by artificial light the flowers appeared a dirty white. This was my experience in the latter part of the present sum-

mer. It is these gross-growing kinds that are so quickly attacked by that dreaded fungus, *Helminthosporium echinulatum*. In low-lying districts and valleys this plays great havoc with many Carnations, and from its mode of growth it seems impossible to eradicate it. Both the upper and under surfaces of the leaves are attacked, and the only thing I have found to check it at all is a mixture of soft soap and sulphur. Damp a bit of sponge

or soft rag in this, and with finger and thumb draw the leaf through. Dip the sponge frequently in the mixture. Where valuable kinds exist they are worth looking after.—E. J.

**Stapelia gigantea.**—In the stove house at Kew there is now a very fine specimen of this remarkable Stapelia in bloom. It has seventeen flowers on it either expanded or in bud, and is probably the finest plant hitherto seen in cultivation in this country. Each flower when spread out to the full extent is nearly 1 foot in diameter, the five segments of the corolla being broad at the base, but tapering to a long fine point, and giving the flower the shape of the conventional star. The whole of the flower—which is the largest of all the Stapelias—is hairy and of a light tawny yellow, this colour, however, being less in evidence than the numerous, irregularly forked and zigzag lines of dull red. Like many other species of Stapelia, the flowers have a disagreeable odour, which is, however, only perceptible at a distance when the sun is shining. The species has been in cultivation some twenty or thirty years, but the date of its introduction is uncertain. It is a native of Zululand and other parts of South Africa.

#### PROPAGATING TREE CARNATIONS.

Those who desire to secure an abundant supply of Carnation blossoms during the autumn months cannot do better than attend to the propagation of these plants at once. It too often happens that the early part of the year is usually recommended for their propagation. This is very well if only medium-sized plants are required, for which 5-inch or 6-inch pots are quite large enough. But where it is the aim to obtain plants of the largest size, that require pots 8 inches across, a start must be made in the autumn months. As a matter of fact, to secure plants capable of yielding from two to three dozen blooms each, the plants must be twelve months old or thereabouts. Moreover, the material obtainable in the autumn for propagating is very different from that procurable in the first three months of the year. In the former the cuttings have more or less been made in the summer and in the open air, while with the latter the cuttings have grown for the most part during the worst season of the year. It is obvious that the latter are not the most satisfactory cuttings, and without a good cutting to begin with it is impossible in future to build up a good plant. Again, during the winter months, heat, more or less, is indispensable to the plants flowering properly, and this will by no means prove of benefit to the young shoots. Under all the circumstances there is much in favour of autumn cuttings, and where these can be obtained, a few at least should be tried for comparison with later propagated stock. The latter, of course, will always be helpful for bringing up a succession of their flowers, and it is scarcely possible, even with the best types of Tree Carnations, to have too many of their flowers during the winter months. For autumn I prefer moderately firm cuttings, not too old or wiry. If possible secure the cuttings with a heel attached, as these root with greater certainty provided the heel is intact. Where the latter is broken, the cutting must be made to a joint. Very sandy soil in well-drained pots should be employed, making the soil rather firm. If the sand is quite dry, scatter a little on the surface of the soil, that it may follow the dibble into the hole and be in contact with the base of the cutting. Where the sand is quite moist, I prefer to use it mixed in the soil only. On the surface it dries so much more quickly than the soil below, and in this way is misleading, frequently causing water to be given when the soil in which the cuttings are is quite wet. Carnations often root well enough in pure sand, also cocoa-nut fibre, but in both these they are apt to lose all their roots in potting them off, otherwise it could be recommended. A close frame having a temperature of 60° to 65° will suit for striking the cuttings. In such a frame a thorough soaking of water must be given at the start, and after-

wards with care. When the cuttings are rooted, no time should be lost in potting them off. On no account should they remain in the cutting pots till a mass of roots is formed, as the major portion will have to be sacrificed at the potting bench. When potted, keep the plants as cool as possible, and water sparingly all the winter. Under this treatment the young plants will be perfectly safe. H. H.

**Winter-flowering plants.**—To the list of good winter-flowering plants of easy cultivation given a few weeks ago in THE GARDEN I may perhaps add one or two more, having found them very valuable at this season and right away until Christmas. *Libonia panrhosiensis* is a much better variety to my thinking than *L. floribunda*, being of more compact habit, brighter in colour, and lasting longer in flower. Cuttings may be inserted in early spring and the young plants transferred first to 2½-inch and ultimately to 3-inch pots, in which they may be allowed to flower. The final potting compost should consist mainly of loam, a sturdy compact growth being thereby encouraged. Nearly the same cultural remarks apply to *Salvia splendens* Bruanti, a very useful autumn flower, its brilliant scarlet hue being much appreciated alike for the greenhouse and for cutting. Its enemies are red spider and the white fly that troubles the Tomato grower. If there is any suspicion of danger from either of these the plants should be syringed with a weak insecticide before the flower-spike is fully formed. I noted last year the merits of *The Lady Primula*, and am glad to say this season's batch is progressing satisfactorily and already flowering well. It may not be a variety that a connoisseur in florists' flowers would be likely to favour, but as a cut-and-come-again winter flower it has few equals, and, despite the somewhat flimsy appearance of the petals, it stands well in a cut state. In the matter of winter-flowering *Pelargoniums*, I am holding fast by a few varieties that have proved about the best for continuous flowering, viz., *F. V. Raspail*, *Guillion Mangilli*, *Constance* and *Queen of the Belgians*, and for West Brighton Gem have substituted *Turtle's Surprise*, a double variety of very similar habit. A house filled with the plants above-named, together with a few *Eupatoriums*, *Cypripedium insigne*, and also occasional plants of winter-flowering Carnations, will, if kept up to a minimum of from 50° to 55°, be bright and cheerful nearly all through the autumn months.—E. B., *Claremont*.

#### BOUVARDIAS.

The exceptionally bright sunny weather which we have experienced during the autumn has been most favourable to Bouvardias. Those which have been flowering will keep up a succession of bloom much later than usual. This is especially the case with *Humboldtii corymbiflora*. Plants which have been flowering since June will go on for a considerable time longer. It is a most useful variety for cut bloom. When given the same treatment as other sorts it does not always prove satisfactory, and I have known several instances where, although other sorts have flowered well, this has been almost an entire failure. Being of different habit and of stronger growth, it requires different treatment. In the first place, it should be given more pot room, and should not be stopped so late in the season as other sorts. For keeping up a succession of bloom through the summer and autumn, cut-back plants may be recommended in preference to spring-struck plants. As soon as the plants have done flowering they may be dried off and cut back. Plants kept well exposed to the light through the winter and in a cool house will break strongly early in the spring. As soon as they have made a good start they should be repotted. The balls may be reduced, and the plants potted again into the same sized pots, or perhaps a size smaller. The syringe should be used frequently, but it is necessary to be careful not to give too much water at the roots

until the pots are well filled with roots. If the plants break out evenly, they may be grown on without any stopping, and will come into flower all the sooner. As soon as the plants are well established they should be exposed to all the sunlight they can get and plenty of ventilation given: in fact, this variety flowers well in the open, but the blooms are easily damaged by wind or rain. If treated liberally the same plants will keep up a succession of bloom from June until the end of October or even later. For winter flowering *Vreelandii* is the most reliable of the white varieties. A later addition to white varieties and one which makes a fine pot plant is *jasminoides paniculata*.

President Cleveland being so far ahead of all other scarlet varieties, it seems strange that other scarlets are still grown, yet such is the case. Of pink varieties, Mrs. Robert Green holds first place, though *Priory Beauty* is extensively grown. No recent additions have been made to the double varieties. Alfred Neuner (the first of the doubles) is still the best, or, I should say, the only white variety. Of scarlets there are several, but *Hogarth flore-pleno* is the only one worth growing. President Garfield, flesh-pink, will complete the list of useful double varieties. Under good treatment few plants are more useful than the *Bouvardias*. A. H.

**Gloxinias.**—These are frequently grown in a much higher temperature than is necessary, and with very unsatisfactory results. I lately saw a house full of young plants which had been grown under cool treatment. The plants in question were raised from seed sown early in February, and the last week in July the first flowers were opening. The pots were covered with large, fleshy leaves, and a little later on they will make a grand show of bloom. One great advantage in growing *Gloxinias* under cool treatment is that they last in bloom much longer, and the flowers when cut will keep better than those from a hot, moist atmosphere.—H.

**Solanum Wendlandii.**—For many weeks during the past summer this showy climber has been producing an almost endless profusion of its delicate mauve flowers in the succulent house at Kew. Indeed, in its flowering it appears almost continuous, judging by the branching manner of the drooping cymes in the plant under notice. Some of these pendulous branches of blossom were quite 18 inches long and nearly a foot wide. Though sometimes regarded as a stove shrub, that at Kew fully demonstrated, by its size as well as its abundant flowering, that it was quite content in cooler quarters. A coloured plate of this was given in THE GARDEN of Feb. 1, 1890.

#### ORCHIDS.

##### SEASONABLE NOTES ON ORCHIDS.

THE long-continued heat and sunshine have given place at last to more seasonable weather, and at the time of writing it is cheerless and dull outside, with a drizzling rain and fog. These conditions are about the worst possible for Orchids, and probably more failures may be attributed to our leaden autumn and wintry skies than to any other cause, as, no matter what care is taken in ventilation, damping and heating or other cultural operations, a nicely balanced temperature, with heat, air and moisture in proper proportions, cannot be maintained. Still, to take the season as a whole, it has been almost unparalleled for its beneficial effects upon horticulture and agriculture generally, and most of us can happily congratulate ourselves upon the good results attained in all departments. Orchid growers in the neighbourhood of large towns will find that for the next few months they have a difficult task before them, the heavy atmosphere bring-

ing with it all kinds of impurities. Near the metropolis it is possibly worse than anywhere else, though the black shiny deposit upon the glass near any of the large manufacturing centres makes Orchid growing in their vicinity anything but easy, and a complaint is already to hand from Manchester respecting it. The first thing needful is of course to clean the glass outside, and this is best done by washing with clean water, which will be necessary as often as twice or even three times a week during foggy weather, or the water may be forced through a hose and the soot swilled off by this means, but this is not so good a plan as the former, as the cold water is sometimes forced through the laps of the glass, causing a cold drip upon the plants beneath. The inside of the glass does not get coated over so quickly, but as often as time can be found to do so, this ought also to be cleaned, using a sponge and rinsing it frequently in clean water. In large houses the sponge may be tied on the end of a stick to prevent climbing about among the plants where the roof cannot be reached without, and with a little practice the work can be expeditiously done. In the cool house, where *Masdevallias*, *Odontoglossums* and other cool Orchids are grown, this is especially needful, for although during the summer these can hardly be too heavily shaded, they require every ray of light that can be afforded them during the dark winter days. All the watering that is now needed at the roots is better done as early in the day as possible, as this allows the surplus water to dry up before nightfall. I always make it a practice to look through the plants daily for water even at the dullest time of year, but when possible water most heavily on bright mornings, and, it is hardly necessary to add, always use water of a corresponding or higher temperature than that of the house. If cold water is used the plants are being constantly checked, and this is quite as bad as allowing the temperature of the house to drop. The *Phalenopsis* have done remarkably well this season and the foliage is firm and healthy, in a capital condition, in short, to pass the winter safely if reasonable care is bestowed upon the plants. Keep them well up to the light and let the Moss about the roots get well on the dry side before giving a fresh supply of water. Plants in cylinders or baskets with the foliage hanging over the sides should not after this be immersed when watering, as it is very important that the leaves are not wetted; it is much better to pour the water on them from a can in the ordinary way, or, better still, to force it through the rose of a syringe, a mode of watering Orchids too little practised by the way. As the earlier plants of *Calanthes*, *Pleiones*, and other winter-flowering Orchids come into bloom the houses begin to look much more cheerful, and as these are soon followed by *Dendrobiums*, the dullest period of the year for flowers may now be said to have passed. The useful old *Cypripedium insigne*, too, in its many forms is again with us, and as the flowers last so long in perfection, this helps to make a display over a very long season. In the *Cattleya* house, *C. labiata autumnalis* is still the principal attraction, and where newly-imported plants are flowering for the first time, it is very interesting to note the variations in colour as the blossoms open. As regards the growth of the plants, a watchful eye must still be kept, for although most of the warm house kinds are more or less at rest, there are always a few that need watching at this time. *Thunias* should by now have lost all their foliage, and will therefore be kept quite dry at the roots. They must be kept fairly warm, and if room is scarce the stems may be shaken out of the pots,

and tied up in bundles of five or six, keeping each kind separately labelled and hung up out of sight as much as possible in the East India or *Cattleya* house, or indeed in any structure where the temperature does not fall below 50° or 55°. *Odontoglossum citrosimum* has finished its growth and must now be placed in a cooler house, the water supply being diminished by degrees until midwinter, when no more will be required until the points of the flower-spikes are seen in the young growths in spring. The distichous-leaved section, too, of the *Vanda* and *Aerides* types are showing, by the tips of the roots clouding over, that they have finished growing for the season. It is never necessary to dry these plants so much as is done in some places; they do not require much water at the roots, it is true, but the atmosphere should always be a little moist to keep the foliage in good order. *Saccolabium giganteum* is a difficult plant to manage in winter, as the spikes are generally then produced, and consequently it requires more support than those that are entirely at rest. The flowers are, moreover, very apt to damp badly if the atmosphere is kept unduly moist, or if water is allowed to lodge about them. Suitable night temperatures will now be from 60° to 65° for the warmest house, according to the species that are grown, the higher temperature being the most suitable for *Phalenopsis* and kindred plants. For *Cattleyas*, 55° will be ample, while in the cool house the temperature should be kept as near 50° as possible. Continue to keep a sharp look out for insects in all the houses, and push forward the clearing of the plants at every opportunity.

H. R.

***Vanda Sanderiana*.**—Numerous as are the fine species the genus *Vanda* contains, there is, perhaps, not one of them which in effectiveness can claim to be the equal of *V. Sanderiana*, although in pure beauty *V. cerulea* and some others, perhaps, are superior to it. It was introduced by Messrs. Sander in 1881 from Mindanao, one of the Philippine Islands, and, for its size, one of the richest hunting grounds for the Orchid collector the world contains. Plants have been known under cultivation to produce a dozen flowers on a spike, but with even half that number the effect is extremely striking and handsome. The three upper segments of the flower are of a pale rosy lilac, tinged with yellow and marked with dots of crimson at the base. The two lower segments are considerably larger, measuring 2 inches across; the fawn-coloured ground is covered with a network of brownish crimson veins. The entire flower, which is flat, like a *Mitonia*, measures 4 inches to 5 inches in diameter. The lip is small and of a dull crimson, changing to greenish yellow at the base. A handsome specimen of this *Vanda* is flowering now at Kew.

***Cypripedium Leeanaum superbum*.**—This splendid variety is one of the largest forms of this variable hybrid, the dorsal sepal being almost wholly white. Originally raised by Messrs. Veitch, it has appeared in other places from the same cross, viz., a superior form of *C. insigne* and *C. Spicerianum*. It is a free-growing and easily-cultivated plant, thriving well under the ordinary routine as advised for warm house *Cypripediums*, and never failing to flower well during the late autumn and early winter months.

***Comporetia coccinea*.**—The brightly-coloured flowers of this charming little Orchid are very acceptable at any time of year, and are especially so just now. It is by no means constant in flowering, the blossoms being sometimes produced in early spring. The flowers occur in small racemes from the top of the pseudo-bulbs just as the plants are finishing up their growths. It thrives well in small pans suspended near the roof in a warm house, and the plants greatly dislike disturbance at the roots; therefore, when ro-

potting only the best of material should be used over good drainage. A little of the old compost may then be removed as often as required and new substituted. The plants require plenty of water all the year round, but especially when rooting freely, and they must be shaded from bright sunshine.

***Odontoglossum aspersum*.**—This is occasionally imported along with *O. Rossi*, and is consequently sometimes met with under that name. It is, however, a much superior plant, the blooms being larger and brighter in colour, a well-flowered plant making a pretty display. The sepals are yellowish, with abundant brown spots, and the petals are nearly white, these having a few spots about the base. The lip is heart-shaped, white, with a yellow centre. *O. aspersum* thrives in a cool house in pots just large enough to take the plants easily. The compost may consist of equal parts of peat and chopped *Sphagnum*, using only a thin layer of this over good drainage. The plants usually commence to grow early in the new year, and, like all in the genus, must be carefully watered. The atmosphere must always be well charged with moisture and the roots never allowed to get really dry. The pseudo-bulbs will be finished up about the end of August or September, and a slight diminution of the atmospheric moisture is then an advantage. The little spikes soon after appear at the base of the pseudo-bulbs and quickly come to maturity. Its time of flowering varies a little according to its time of starting, but it is usually the late autumn or early winter months.

***Camarotis purpurea*.**—In the rush for new and more showy Orchids, this old species is almost entirely neglected and it is very rarely seen. It is a bad plant to travel, as it often arrives more dead than alive, from which state it is difficult to bring it round. Many plants arrive in this country to be thrown away or to eke out only a very miserable existence. Probably trade collectors seldom trouble to bring it home, but I have several times received it from seafaring friends, who pick it up for next to nothing in the markets at Calcutta, it being brought there by the natives when in flower. It belongs to the distichous-leaved section, the foliage being small and narrow, forming a kind of creeping or twining stem as it is developed. The racemes are about 6 inches in length, very freely produced, and rather densely set with the pretty little rosy pink flowers. As mentioned above, the plants are rather difficult to start, but when once established they grow freely enough. They thrive well where plenty of heat and moisture is afforded them in baskets or pots in a compost consisting chiefly of *Sphagnum* and charcoal. When the growth is finished the plants must be rested by partially withholding water and slightly lowering the temperature. The flowers are produced successively during the summer, a single plant often keeping in flower for four months.

***Cattleya labiata picta*.**—This is a deeply coloured and richly marked variety, the sepals and petals being broad and of good substance, and of a very warm rosy crimson. The lip has a deep velvety crimson blotch in front, the side lobes being lighter with two pure white blotches over the throat, the latter being deep yellow. The spikes are large, a plant now in flower with me having two, each bearing four flowers. The growth is more vigorous than that of some of the other varieties. Taken as a whole, the flowers very much resemble those of a fair *C. Mendeli*.—R.

***Oncidium varicosum*.**—This is one of the showiest of all the *Oncidium*s and a beautiful Orchid. On well-grown plants the spikes are upwards of 20 inches in length, much branched and crowded with the bright yellow flowers. The lip of this species is large and broad, of the brightest yellow, the sepals and petals rather small. This plant must be strongly grown in order to make a good display, and the best mode of culture is perhaps to grow it in baskets suspended from the roof in the *Cattleya* house.

Three parts of Sphagnum Moss to one of peat fibre, with plenty of rough lumps of charcoal and potsherds, will grow it well, and the drainage must always be free and open. These immense panicles of flowers of course constitute a severe strain upon the plants, and unless they are really healthy and strong the spikes ought to be cut before they fade. *O. varicosum* requires an abundant supply of water at the roots while growing, and this must only be partially withheld after the flowers are past until the plants again commence to grow. It is a variable plant, the best by far of the varieties being *O. v. Rogersi*, which has really magnificent flowers, the lip being very broad and highly coloured.

## SOCIETIES AND EXHIBITIONS.

### ROYAL HORTICULTURAL SOCIETY.

OCTOBER 29.

Of perceptibly less extent, but no less interesting, was the meeting held on the above date. Taking into account the severe frosts of the past few nights, it was not to be wondered at that some growers whose wont it is to exhibit plants of tender character were on this occasion somewhat cautious. Hence, no doubt there were fewer exhibits of Orchids than usual as plants. *Chrysanthemums* are now advancing rapidly; the plants and cut blooms shown at this meeting, if indicating what to expect during the next month, speak well for the season. A well-grown group, bearing flowers of fine quality, came from Messrs. Veitch and Sons. New kinds, chiefly of the Japanese section, were present in considerable numbers and from the best known exhibitors. A well-coloured set of dwarf *Crotons* came from the garden of Mr. S. F. Fisher, Streatham. An uncommon, but not new, bulbous plant was shown by Messrs. Wallace, of Colchester, under the name of *Lycoris aurea*, an introduction from China as far back as 1777, thus affording another instance of what really fine things we have which are not nearly well enough known. It is in the way of a *Guzmania* Lily, but is more nearly allied to the *Amaryllis* family, a synonym being *A. aurea*.

Of Orchids, *Cattleya labiata* again held sway, several really fine plants being shown, as well as cut flowers in astonishing variety. Hybrids, chiefly of Veitchian origin, were also present; for the finest of these, reference should be made to the list of awards. A small, but choice group came from Mr. Measures' collection, amongst which *Oncidium ornithorrhynchum album* was conspicuous, and from Mr. Statter some very fine forms of the queen of *Cattleyas*, *C. aurea*.

Of fruit, there was less than at the previous meeting, a very representative collection from Syon House by Mr. Wythes being the most noteworthy. Another good collection of vegetables was staged, some eighty vars., wherein the Carrots and Carrots were the finest examples, the exhibitor on this occasion being Mr. Empson, of Ampthill. A very fine exhibit of Potatoes, consisting of varieties of the very highest quality, came from Messrs. Sutton and Sons, comprising varieties of the firm's introduction, including several not in commerce and of a distinct type from those usually grown. Messrs. Cannell and Sons also had a very fine display of Potatoes, which included the best kinds for garden and field culture, quality being a leading feature. Melons were still *en evidence*, being at the same time of excellent flavour for the lateness of the season.

#### Orchid Committee.

First-class certificates were awarded to—

*CATTELEYA MANTINI* (*C. Bowringiana* × *C. Dowiana*), which at the meeting held on October 15 last received an award of merit when shown by Messrs. J. Veitch and Sons. A more vigorous example, evidently an older plant, was now sent from Mons. G. Mantin, Chateau de Bel-Air, Olivet, France, whilst cut blooms came from

Messrs. Veitch and Sons, the same award being made to each exhibitor.

*CATTELEYA AUREA JOHNSONIANA*.—A very remarkable and decidedly distinct form of this handsome species, in which the colouring of the sepals and petals showed the greatest diversity, being in this instance of a pale creamy tint with a rosy suffusion towards the extremities; the lip was unusually fine, a deep crimson-purple, the rich golden veins extending more nearly to the edge, which was beautifully crisped. From Mr. T. Statter, Stand Hall, Manchester.

Awards of merit were given to—

*CYPRIPEDIUM INSIGNE LAURA KIMBALL*.—A very chaste and beautiful form of this popular species, much in the way of Sander's fine variety, but distinct from it, the absence of any spots being the same feature, the entire flower being of a deeper tint of golden yellow with the dorsal sepal relieved by a pure white margin. From Messrs. H. Low and Co., Upper Clapton.

*LÆLIO-CATTELEYA EUPHROSINE* (*C. Warszewiczii* × *Lælia pumila* Dayana).—Another of the dwarf hybrids, of which some few fine forms have already been shown from the same source. The latter parent has monopolised the habit and the style of the flowers to a great extent, but the soft roseate tints of the sepals and petals point to its other parent, the lip being lighter in comparison, with deep vinous-purple markings and two distinct creamy blotches in the throat. From Messrs. J. Veitch and Sons.

*CATTELEYA EURYDICE* (*C. labiata* × *C. Aclandiae*).—A remarkably distinct hybrid, in which the size more nearly approaches that of the former parent with the wax-like substance of the latter, but devoid of the bars and spots as seen in its sepals and petals, which in the hybrid are of a pale fleshy pink with a few crimson-purple spots instead; the lip is of a velvety crimson-purple shading off to a paler tint, with a golden blotch in the centre. From Messrs. J. Veitch and Sons.

*CYPRIPEDIUM ALLANIANUM SUPERBUM* (*C. Spicerianum* × *C. Curtisi*).—A very fine hybrid, and one that is singularly intermediate in character. The dorsal sepal is that of *C. Spicerianum* in a most marked degree, the lip quite as much that of *C. Curtisi*, whilst the petals have the form of those of the former and the markings of those of the latter parent to a great extent. The combination in this instance has resulted in a singularly fine hybrid. From Mr. R. J. Measures' collection.

*CATTELEYA BOWRINGIANA GIGANTEA*.—A very superior variety of this handsome autumnal species, paler in colour perhaps than in some instances, but none the less beautiful. The petals were very noteworthy as being of great breadth, quite overlapping the sepals, the flower being of extra size; the lip, on the other hand, was perceptibly darker, with a creamy throat, the entire spike a very fine one. From Mr. Geo. Hardy, Timperley, Cheshire.

A botanical certificate was awarded to *Houlletia tigrina*, a dark spotted variety from Sir Trevor Lawrence's collection.

To Mr. T. Statter a silver Flora medal was awarded for some choice cut flowers of *Cattleya aurea*, very richly coloured. *C. aurea magnifica* was one of the finest of these, the labellum of unusual size and of most intense colour towards the margin. Several other good examples were shown. *Cattleya labiata* was also well represented, the flowers of extra size and of a wide range in colouring. One form named *elegans* has mottled or marbled flowers in dark and light shades of purplish mauve and crimson; another called *Excelsior* is of unusual size and very deeply coloured throughout. *Cypridium Spicerianum* *viridescens* in which the green predominates was shown here. *C. Edwardi*, one of the *C. Fairrianum* type of hybrids, was also included. To Messrs. Hugh Low and Co. another silver Flora medal was awarded for a splendid group, consisting largely of *Cattleya labiata*, which is evidently one of the firm's specialties. The varieties of this splendid autumn *Cattleya* were a study in themselves. The plants being very vigorous, had thrown up some splendid

spikes of large and richly marked flowers, whilst other plants were quite large masses. *Cypridium Charlesworthi* was present, also being quite a specimen, the dorsal sepal as usual being its most attractive feature. Another form of this species called *unicolor* had the colour of the lip as seen in the type pervading the entire flower. *C. Lowi*, always attractive, was also included; so also were well-flowered examples of *Oncidium varicosum* and a nice plant of *O. ornithorrhynchum album*.

Mr. R. J. Measures, Cambridge Lodge, Camberwell, received a silver Banksian medal for a bright and choice group, amongst which was again shown the very fine plant of *Oncidium ornithorrhynchum album* freely flowered. Mr. Chapman is to be congratulated on his admirable management of this plant; on this occasion it bore fifteen spikes. *Cymbidium longifolium* (syn., *C. cyperifolium*) was also shown here, two examples being put up; it is after *C. Tracyanum*, but much smaller in all its parts. *Cypridium Annie Measures*, bearing the third flower upon the spike, was staged in good condition; so also was *C. Charles Rickman*, which received a certificate under the name of *C. Meteor*; this had two flowers to the spike. *C. Zeus* (*C. callosum* × *C. ciliolare*), a fine and quite intermediate hybrid; also *C. Leeanum superbum*, specially good, were both included; so was the Cambridge Lodge variety of *C. insigne*, which has large spots on the dorsal sepal, and *C. Arthurianum*, which appears to flower at almost all seasons of the year. *Cattleya Hardyana* was well shown here, and so was *C. labiata*. One notable feature in this group was the many previously certificated plants. Mr. Hardy, Timperley, received the same award for a showy collection of cut flowers of *Cattleya labiata* of the greatest diversity, from the deep and richly coloured forms to that choice variety *Cooksonæ* which was certificated at the last meeting. *C. labiata alba* was also excellent; it has the purest of white sepals and petals, also the lip save the golden pencillings in the throat. *Cattleya Harrisii* (*C. guttata* *Leopoldi* × *C. labiata* var.) was also shown well; the flowers have the substance of *Leopoldi* with the form of lip, whilst the colouring and size partake more of those of its other parent.

Smaller exhibits comprised an extra fine truss of *Cattleya labiata* bearing five grand flowers, the colour being also very bright, from Mr. Wilberforce Bryant, Stoke Park, Slough. Messrs. J. Veitch and Sons showed in addition *Cypridium Bruno*, a hybrid after *C. Spicerianum*, with the lip more obtuse, whilst the dorsal sepal was of extra size; *C. Thora* (*C. insigne* *Chantini* × *C. politum*), a distinct looking flower, pale bronzy red in colour with a broad creamy margin to the dorsal sepal; also *Lælio Cattleya Statteri* (*C. labiata* × *C. Perrini*), a very choice and decidedly distinct hybrid, the sepals and petals after *C. labiata* and the labellum in the way of *C. Perrini* marked with rich violet-purple. Mr. Young, Sifton Park, Liverpool, had a malformed *Cattleya labiata*, also *Cypridium Clotho*, a dark lustrous-looking hybrid. Messrs. Lewis and Co. showed *Oncidium varicosum* with large flowers, also *Cattleya labiata*, a distinct form, and *C. aurea*, as well as *Cypridium* in variety with *Phalaenopsis Kimballiana*.

From Messrs. Sander and Co. on this occasion came another well-flowered, healthy plant of *Habenaria Susanne*, with four spikes of its pure white blossoms; *Lælia marginata*, a lovely dwarf species with pale rosy mauve sepals and petals, shading off at the edges to nearly white, the lip having a dark crimson blotch; *Cattleya labiata* in most excellent varieties, one of which had the labellum of unusual size, and another with rich golden shading in the throat; *Sophranitis grandiflora*, dwarf plants, with many flowers; *Calanthe Clive*, a dark red hybrid with a milky white blotch on the lip, and *C. Florence* (*C. bella* × *C. Veitchii*), a bright crimson-red, with the sepals darker and the flowers of good form. *Oncidium Rogersi* and *O. tigrina* here were both excellent examples of these fine *Oncidium*s. *Zygopetalum crinitum* and *Catasetum Christyanum* were both to be seen. From Mr. G. C. Raphael, Englefield

Green, came a richly coloured spike of *Vanda cœrulea* called after the exhibitor, also *Cattleya labiata*, a dark form with large flowers, and *Zygopetalum Burkei*, which was certificated in 1883. From Mr. Wingfield's garden, Amphill, came yet another variety of *Cattleya labiata*.

#### Floral Committee.

A first-class certificate was awarded to—

**LYCORIS ATREA**, which will be found noted on another page. A basket containing several plants each carrying a good spike of flowers was shown by Messrs. R. Wallace and Co., of Colchester.

Awards of merit were granted to the following—

**BEGONIA SUCCESS.**—This is another useful addition to the winter-flowering kinds, and is the result of crossing *B. socotrana* with a pink-flowered tuberous rooted variety. It resembles the former parent in foliage, but its habit of growth partakes more of that of the tuberous-rooted kind. It grows erect, blooms very freely, its flowers deep rosy-carmine, of fine size, and exhibiting a tendency to doubleness, the centre of the flower being a mass of little petals. The arrangement of the flowers upon the stems too differs from, and is rather more irregular than that of, the tuberous varieties. It was shown by Messrs. J. Veitch and Sons, Chelsea.

**CHRYSANTHEMUM MRS. BRISCOE-IRONSIDE.**—A lovely Japanese incurved kind with long intermingled petals and a fine full flower of a tender blush colour, quite distinct from any other variety shown at the meeting. Raised and shown by Mr. H. Briscoe-Ironside, Burgess Hill, Sussex.

**CHRYSANTHEMUM MISS FLORENCE LUNN.**—This is a reflexed kind, and has a full deep flower of a distinct rich shade of crimson-amaranth and of medium size. It was also raised and shown by Mr. H. Briscoe-Ironside.

**CHRYSANTHEMUM MISS DOROTHY GIBSON.**—This also belongs to the reflexed class, and has a large, deep flower, rather above medium size and of a telling rich yellow colour. It is an English seedling, raised and shown by Mr. R. Owen, Maidenhead.

**CHRYSANTHEMUM ROSE OWEN.**—An incurved variety, with a full flower of fine depth and perfect finish, in colour bright lilac-rose, lighter towards the centre, where the florets are tipped with white.

**CHRYSANTHEMUM EDITH TARBOR.**—A Japanese variety of reflexed form, large and bold in appearance, and in colour rich yellow, the petals long, broad, and somewhat intermingled. It was shown by Mr. R. C. Notcutt, Ipswich.

**CHRYSANTHEMUM MRS. CHARLES BLICK.**—Of white Japanese varieties there appears to be no end, and yet in this we have one of undoubted merit, as dwarf and robust in habit as it is fine in flower. Thirteen plants of it were shown, none of them more than a yard high, but each crowned with a grand flower, made up of a deep, dense, but graceful spreading mass of long florets, which incurve slightly at their tips. It is of the purest snow-white, and was shown by Mr. C. Blick, gardener to Mr. Martin R. Smith.

**CHRYSANTHEMUM QUEEN OF BUFFS.**—A distinct Japanese kind, of the colour that its name suggests, the outer flowers recurring somewhat, those of the centre incurved, the petals of ample breadth and slightly flushed with rose along their edges. Shown by Mr. H. J. Jones, Lewisham.

**CHRYSANTHEMUM MRS. E. G. WHITTLE.**—This is a Japanese incurved, with large flowers, broad in petal, bold in outline, and of a pretty cream-white shade. Also from Mr. H. J. Jones.

**CHRYSANTHEMUM C. H. CURTIS.**—This is an incurved variety, extra large for its class, and lacking somewhat the perfect finish usually sought for in flowers of this class, but in its rich colour it is an acquisition. It was shown by Mr. H. J. Jones.

**CHRYSANTHEMUM MISS ANNIE HOLDEN.**—A single-flowered variety, but a welcome addition to this class, deserving a place among the best of them. It bears its flowers freely in sprays and they are of a distinct shade of fawn-yellow, a clear and decided tint. It also came from Mr. H. J. Jones.

**CHRYSANTHEMUM BEAUTY OF TEIGNMOUTH.**—This is a Japanese variety of the *E. Molyneux* type, with large flowers, broad in the petal and extremely showy. The inside of the florets is a rich crimson, but their reverse is white, lined and flushed with rose; the outer ones droop, but those of the centre incurve. It was shown by Mr. J. Agate, Havant.

**CHRYSANTHEMUM MONS. CHENON DE LECHE.**—This is one of M. Calvat's fine kinds, a Japanese reflexed, the flower full, very fine, and of a colour not easily described—a sort of rosy buff, soft and distinct in appearance. Shown by Mr. W. Wells, Redhill.

**CHRYSANTHEMUM YELLOW SOURCE D'OR.**—This is what the name suggests, and of a rich, almost orange-yellow shade, but it would be better in many ways to give a distinct kind an entirely new name, even though it be a sport. It was shown by Messrs. Cannell and Sons.

There was little else for the consideration of the floral committee but Chrysanthemums, and these were mainly varieties shown for certificates; but from Messrs. J. Veitch and Sons, Chelsea, came an admirably arranged group of plants mostly of Japanese kinds, and each carrying from three to five fine blooms. Among the numerous varieties here shown, the following were particularly fine: Mrs. W. H. Lees, white; Mme. Carnot, white; Mons. Ch. Molin, bronze and yellow; Louise, white; William Seward, crimson; John Shrimpton, rich crimson; International, pale cream; Eva Knowles, rich apricot; Charles Davis, yellow; Miss L. D. Black, rich yellow; Sunflower, yellow; Queen of Buffs, Col. W. B. Smith, Mons. G. Biron, G. W. Childs and G. C. Schwabe. A silver Flora medal was awarded this fine group, which well represented the newest and best kinds at present obtainable. A brightly coloured group of Crotons was exhibited by Mr. G. Bond, gardener to Mr. S. T. Fisher, The Grove, Streatham, the plants all being in 4½-inch pots. Many varieties were shown and the condition of the plants showed skilful culture. A silver Banksian medal was awarded. Mr. Anthony Waterer, of Woking, exhibited a large tree about fifteen years old and nearly 20 feet high of *Quercus americana coccinea splendens*, of which every leaf was of a bright vermilion-red, as vivid as that of the *Liquidambar* in its brightest colour, but markedly superior in other ways, for whereas the *Liquidambar* loses its leaves early, those of this Oak hang persistently, and lose little of their brightness till nearly Christmas. Mr. W. Wells, of Redhill, showed several fine novelties in Chrysanthemums, as *Reine d'Angleterre*, rosy mauve with silvery white reverse; Mons. H. J. Jones, rosy red with amber reverse, and Mme. Aug. Gœbe, white, spotted and flushed with pink, a distinct flower in form and colour. Messrs. B. S. Williams and Son, Holloway, showed the variety *Reine d'Angleterre* and a variegated red-flowered *Bouvardia*. *Chrysanthemum Fulwell Park*, shown by the Dowager Lady Frake, is a distinct sport from *La Triomphante*. Messrs. Cannell showed *Kentish White*, which strongly resembles *Louise*, *Source d'Or* and two sports from it, *Miss A. Holden*, the pretty single kind, and several others, notably two pompons with thread-like petals. Miss Elsie Teichmann and Maggie Shea, both very fine Japanese kinds, were shown by Mr. C. E. Shea, the former cream white, and the latter rich yellow. Miss Bostock, shown by Mr. R. C. Notcutt, is distinct, with long, narrow, erect petals, its colour rosy-lilac. Mr. H. J. Jones had several superb varieties besides those already described, in James Murray, D. B. Crane, and Mme. Moulin. Mr. R. Owen, Maidenhead, Mr. W. E. Tidy, Havant, Mr. Stevens, Putney, and others also exhibited new varieties that do not call for special comment. Mr. H. Briscoe-Ironside arranged and showed revolving stands made for six and twelve blooms respectively, apparently designed to improve upon the existing showboard method of arrangement. Several other varieties of *Begonia* of the same cross as that which received an award were shown by Messrs. Veitch, embracing different shades of

colour, and cut flowers of *Iilium nepalense* were shown by Messrs. R. Wallace and Co., Colchester.

#### Fruit Committee.

The exhibits before this committee were numerous, vegetables and salads being shown in quantity and of excellent quality.

Awards of merit were given to—

**MELON ANTHONY'S FAVOURITE.**—A scarlet-fleshed, netted, roundish fruit of good flavour for so late in the season. It is of medium size and with a good depth of flesh. From Mr. Empson, Amphill House, Bedford.

**APPLE PAY THE RENT.**—A late variety, above medium size, roundish, similar to Wellington, but may be used for kitchen or dessert. From Mr. R. Fenn, Sulhamstead, Reading.

An extensive collection of vegetables occupying much space with forty varieties of Gourds was staged by Mr. Empson, Amphill House, Bedford. He had very fine Carrots in eight varieties, Matchless and Perfection being the best; good Veitch's Protecting Broccoli, Major Clarke's and Solid White Celeries, Chirk Castle, Orange Jelly, and Milan Turnips, good Tomatoes, Beet in three varieties, Ailsa Craig Onions, eighteen varieties of Potatoes, Cardoons, Salsafy, Brussels Sprouts, and Lettuces (silver gilt Knightian medal). Messrs. Sutton and Sons, Reading, had an extensive display of Potatoes, over thirty-one varieties being of their own introduction, including the well-known *Magnum Bonum*, still one of the most profitable croppers grown, *Supreme*, *Windsor Castle*, *Flourball*, a new variety of great excellence sent out last year, *Satisfaction*, *Triumph*, *Abundance*, and *Ringleader*, all noted for their shapely tubers and excellent quality. A large collection of seedling Potatoes not yet in commerce, from which great things may be expected, was also shown. The whole formed a very interesting display (silver Knightian medal). Messrs. Cannell and Sons, Swanley, Kent, staged 100 dishes of Potatoes, also Leeks, Turnips, and Coleworts in quantity. The best Potatoes were Mr. Breese, *Beauty of Hebron*, *Early Vermont*, *King of the Russets*, and *Eynsford Mammoth*. Several new and promising seedlings were also included (silver Knightian medal). Mr. G. Wythes, Syon House, Brentford, staged a nice collection of salad in twenty-six varieties, including *Endive*, beautifully blanched and of excellent quality; *Early Rose* and *Superb White Celeries*, *Radishes* in variety, *Sorrel*, *Chicory*, *Paris Green*, *Hick's Cos* and *Harbinger Lettuces*, four varieties of Tomatoes and Cucumbers (silver Banksian medal). From the same exhibitor came a collection of eighty dishes of Apples, Pears, Plums and Quinces. *Cox's Orange*, *Ribston*, *King of the Pippins*, *Royal Russet*, *Brownlee's* and *Egremont Russets* were of excellent quality. Among the cooking varieties, *Bismarck*, *Cadini*, *Tower of Glamis*, *Alfriston*, *Hawthornden* and *Warner's King* were good; *Beurré Diel*, *Nouvelle Fulvie*, *Brown Beurré*, *Pitmaston*, *Beurré Clairgeau* and *Van Mons Leon Leclerc* being the best Pears. A nice lot of *Wyedale Plum* was also shown here (silver Banksian medal). Messrs. D. and W. Buchanan, Forth Vineyard, Kippen, Stirling, staged a very interesting collection of fruit and Tomatoes, the Grapes being arranged with highly-coloured foliage and suspended to wires. There were very fine bunches of *Gros Colman* in baskets, also *Alnwick Seedling*. The whole formed an interesting display (silver Banksian medal). Mr. C. E. Shea, Foot's Cray, Kent, sent very fine baskets of *Gascoigne's Scarlet Apple*, splendidly coloured, and two dishes of *Medlars*. Mr. R. Fenn, Sulhamstead, sent seedling Potatoes in two varieties. Mr. Wythes sent good examples of *Celery*, or *Turnip rooted Celery*. Mr. O. Thomas sent seedling Melons *The Duchess* and *Frogmore*, but not in condition. Mr. A. Waterer had a nice-looking Apple named *Sanspareil*. Mr. Fenn sent a seedling Apple besides the one mentioned above.

The lecture given by Mr. Arthur W. Sutton on Potatoes was listened to by a large audience,

and it was made additionally interesting owing to the large number of lantern slides used to illustrate the lecturer's remarks. He traced the history of the Potato down from its earliest days, when it was looked upon as a luxury, till the early part of the present century, when its importance as an edible tuber became better known, and interesting statistics were given of the acreage of land now devoted to Potatoes, and the average yield in tons in Great Britain, France, and Germany. The details of cross-fertilisation and seed-raising were minutely explained. In reference to *Solanum Maglia*, which grows in swampy places, it was thought it might, by intercrossing with *S. tuberosum*, be a means of obtaining varieties less susceptible to disease in wet seasons. The lecturer mentioned that, although many hundreds of flowers were artificially fertilised, only five seed berries were obtained and from these only two seedlings were raised. After growing the progeny several years, the crop was last year almost entirely lost by disease. Still without the intervention of this species we now had disease-resisters, a series of pictures of which were thrown upon the screen, the lecturer remarking that Flourball did not last year have a single diseased tuber. As regards the spraying for disease, he was of opinion, based upon experiments, that it was only necessary for the late kinds that were likely to be affected by disease before the growth of their tubers was complete, and it certainly paid to do it in regard to these. He concluded by telling and showing the results of a curious cross experiment by grafting the Tomato on to the Potato, and *vice versa*. This experiment is to be further continued by sowing the seeds which the respective plants have ripened.

#### NATIONAL CHRYSANTHEMUM SOCIETY.

A MEETING of the general committee was held at Anderson's Hotel, Fleet Street, on Monday evening last, when Mr. Wynne occupied the chair. The secretary announced that prize-money amounting to £45 10s., and awarded at the recent October show at the Royal Aquarium, had been paid to the exhibitors and that the following medals had been awarded for miscellaneous contributions to the show: Silver-gilt medals to Messrs. J. Laing and Sons, H. Deverill, H. Berwick, H. J. Jones, J. Cheal and Sons, T. S. Ware and H. Cannell and Sons; silver medals to Messrs. W. Spooner and Sons, Veitch and Sons, Dobbie and Co.; small silver medals to Messrs. Godfrey, Cutbush and Son, and W. Wells; bronze medals to Messrs. Such, Tidy and H. Shoemith. These awards having been made by the arbitration committee were confirmed. A motion was then made requesting the secretary to call attention to the bad lighting in the early part of the evening at the last exhibition of the society, and to point out the necessity of the Aquarium authorities providing a better illumination during the November show.

A great deal of attention was given to the consideration of the society's jubilee celebration next year and discussion and acceptance of special prizes.

The jubilee celebration will take the form of—1. An immense exhibition of Chrysanthemums in London on November 3, 4, 5 and 6, 1896, in which all types of the flower will be fully represented, also of fruit, vegetables, &c., and which will extend over four days, with a further competition and an entire reconstruction of the exhibition on the third day. 2. A grand opening ceremony and private view at noon on the first day. 3. A conference of Chrysanthemum growers and raisers from all parts of the world. 4. A jubilee banquet at the Hotel Metropole and other festive gatherings. 5. The striking of jubilee medals of value for competition, and for rewarding such persons as have rendered conspicuous service in promoting the advancement, cultivation and improvement of the Chrysanthemum. 6. The preparation and publication of an exhaustive jubilee catalogue of Chrysanthemums, with the most complete classification.

The committee will be happy to receive offers of special prizes from those in sympathy with the jubilee celebration.

A special prize fund (£1000) will be opened, and it is hoped that growers in all parts of the country interested in the flower will do their utmost to raise the required amount. It was also resolved that, following the precedent set in 1890 on the occasion of the Chrysanthemum centenary fête, a special bronze jubilee medal be placed at the disposal of every affiliated society for competition at their local shows in 1896. The schedule of special jubilee classes was then passed, and will be issued to the public shortly. It was resolved that the floral committee be invited to the judges' luncheon on the occasion of the December show, when it is proposed to consider and revise, if necessary, the existing regulations concerning the awarding of certificates. The society's annual dinner will take place on Wednesday, November 27, when the president, Sir Edwin Saunders, will occupy the chair. Mr. G. Gordon called attention to the proposed issue of a new jubilee official catalogue, and suggested that experts in various parts of the country should be called upon, as in 1888, to elect what varieties should be included in the new edition. In reply, it was stated that the catalogue committee would hold a meeting that evening and present its report in due course.

On Wednesday last a meeting of the floral committee of this society was held at the Royal Aquarium, Westminster, Mr. T. Bevan presiding. There was a good display of novelties submitted for adjudication, although perhaps somewhat smaller in extent than might have been expected. The following were the principal contributors to the meeting: Monsieur Ernest Calvat, Messrs. H. Cannell and Sons, Mr. H. J. Jones, Mr. C. E. Shea, Mr. W. Seward, Mr. R. Owen, and Mr. H. Briscoe-Ironside. The selection was a remarkably rigid one, and first-class certificates were awarded as below:—

**CHRYSANTHEMUM YELLOW SOURCE D'OR.**—Japanese; a fine golden yellow sport from the old Source d'Or, a well-known decorative variety. Staged by Messrs. H. Cannell and Sons.

**CHRYSANTHEMUM KENTISH WHITE.**—A Japanese incurved of good build, being solid and substantial, with grooved florets of medium width. Colour creamy white, centre faintly tinted yellow. Also shown by Messrs. H. Cannell and Sons.

**CHRYSANTHEMUM AUSTRALIAN GOLD.**—A prodigious Japanese, very full and double. Colour rich canary-yellow, tinted lemon, reverse silvery yellow. A seedling, raised by M. Ernest Calvat, who was also the exhibitor.

**CHRYSANTHEMUM MRS. BRISCOE-IRONSIDE.**—A large Japanese incurved, very globular in form, with regularly incurving florets. Colour soft salmon-blush. Raised and exhibited by Mr. H. Briscoe-Ironside.

Among other meritorious novelties mention may be made of Mrs. E. Seward, large incurved Japanese, pale carmine, with golden buff reverse and Master Jas. Epps, a massive-looking Japanese, rich golden yellow, which the committee desire to see again. M. de la Rocheterie, Japanese incurved, inside colour pale carmine-chestnut, reverse yellowish buff, was also good. Several incurved varieties of the old show type were staged, viz., Mr. Jas. Murray, George Haigh, an excellent golden buff sport from Robt. Petfield, and Rose Owen. Other Japanese varieties that look promising were Duchess of Fife, white, Miss Clara Walker, white, Queen of Buffs, Ada Fulford, Mrs. J. G. Whildin, fine yellow, Maggie Shea, and Lord of Lorne.

**The plague of birds.**—If Mr. Sangwin will refer back to p. 152 of your present volume he will find that as long ago as the middle of August I was complaining of these feathered pests, and ascribing the cause to our ridiculous latter-day legislation. Only yesterday (October 29) I gathered two trees of Dumelow's Seedling, and nearly half

the crop was damaged by birds and wasps—these latter being this season more destructive than ever before—their depredations lasting until the middle of October, a later date than I can recollect. Curiously enough, I have found starlings the most destructive birds among fruit this summer. I had previously reckoned them as the gardener's friends. —AN OXFORDSHIRE AMATEUR.

#### NOTES OF THE WEEK.

**Lycaste armeniaca** was imported with and is no doubt a variety of *Lycaste Skinneri*. It differs principally in the colouring. The sepals are creamy white, the petals and lip bright salmon. A fine plant of this scarce variety is now in flower in Messrs. F. Sander and Co.'s nursery.

**Nottingham Med'ar.**—I send you a Medlar from one of the trees in my garden. There are many more as large. I never remember such fine crops of Medlars and Quinces; the latter are a splendid sight, the great golden fruit hanging in ropes. One cause of these fine crops is doubtless the entire absence of frost from the time the Medlars and Quinces began to flower.—WM. WICKHAM, *Birsted Wyck, Alton, Hants.*

**Erodium supracinerum.**—I see this plant mentioned in THE GARDEN of October 12. One planted here last November had no protection during the winter and has flowered very freely from the end of May to the middle of October. I sent some seed pods to Mr. J. Wood, from whom I obtained the plant. I should be glad to know whether *E. supracinerum* is the equivalent of *supracanum* of the Kew hand-list of herbaceous plants.—E. C. BUNTON, *Bettws-y-Coed.*

**Iris unguicularis (stylosa)** has already commenced flowering at Kew, perhaps in consequence of the unusual heat. It does very well in a narrow border against the wall of the Orchard house, and there were several of its lovely mauve-blue, sweet scented flowers fully expanded on long stems thrown well above the tufts of grassy leaves. It is a precious winter flower in its normal season, and worthy of as much attention as *I. reticulata* in its several fine forms.

**Dahlia Mrs. Peart.**—Replying to "C. W.'s" query on page 325, we had this early in the season quite double and without a trace of the yellow centre. Amongst the flowers exhibited by us at Shrewsbury were two model blooms, and a month ago we had two plants in pots, each carrying blooms without the yellow centre, in fact as double as any others we were showing at the same time. Several who saw them said they were the finest and most perfect blooms they had ever seen of this variety. We might, however, add that as the season advanced the flowers showed more and more of the centre, till the last few had only two or three rows of petals.—POPE & SONS, *Birmingham.*

**A fine Lobelia.**—I am sending for your inspection and opinion a spike of bloom and foliage of a seedling Lobelia which I have grown largely for the past two seasons. It is the hardiest of all this class, being a robust grower and rooting deeply. It stands the winter. You will observe the peculiar green of its stems and foliage. It remains in full beauty much longer than any other Lobelia. Last autumn it was beautiful on November 24, and has all the appearance of continuing as late this season. It is a seedling from my Lobelia Firefly.—ANDREW CAMPBELL, *The Gardens, St. Anne's, Clontarf, Co. Dublin.*

\* \* A very tall (5 feet) and handsome Lobelia, partaking more of *L. cardinalis* than *L. fulgens*. —ED.

**Nymphaea cœrulea out of doors in Sussex.**—I have for several years flowered *Nymphaea cœrulea* in a small tank in my Orchard house, and as the Lilies outgrew the tank, I put one in a pot into a pond lately excavated in a wood at a depth of about 18 inches. This was done in the summer of 1894. It was knocked out of the pot in the

spring. To my astonishment it lived all through the severe cold of last winter, and though it has not fully flowered, yet it has budded sufficiently to show that in a more sunny spot it might come to perfection. I enclose two of the buds. Arums also which were placed in the same pond in 1894 survived the winter and flowered this summer. Are not both these cases unusual?—G. H. THURLOW, *Buckham Hill, Uckfield, Sussex.*

**Arachnanthe (Vanda) Lowi.**—This species was first discovered by Sir Hugh Low in Borneo and sent to the Clapton nursery about 1846. A grand specimen with eight growths carrying four racemes, with an average of upwards of thirty flowers on each, is now in flower in Messrs. Sander and Co.'s nursery at St. Albans. The two lower flowers on each raceme are, as is usual with this species, rather larger than the others and of a bright orange-yellow dotted with reddish purple, while the others are deep chocolate-brown bordered and streaked with yellow. The plant thrives best in pots with broken crocks worked firmly between the roots and around the stem. The surface should be made up with good live Sphagnum Moss. It requires plenty of moisture the whole year through.

**The Cornish Heath (Erica vagans).**—This Heath is valuable for the late autumn days, and we are surprised not to see it more frequently in gardens. Quite recently at Craggs, in the heart of Northumberland, and in Jesmond Dene, Newcastle, we have seen glorious groups of this Heath fine in effect at a time when most gardens or garden shrubberies are bare of bloom. The past winter dealt hardly with some of the South European Heaths, but, after all, it only accentuated the importance of the absolutely hardy and most beautiful kinds. *E. carnea* spread out its gay cushions of colour immediately the cold had passed away, and now we have the Cornish Heath (as is its wont) carrying on the time of Heath-blooming till the buds of *E. carnea* show colour again. In the whole family of hardy Heaths none are more graceful than this, with its long, tapering, plummy shoots crowded with myriads of blossoms. At Kew this Heath is now also very pretty.

**Lycoris aurea** is a charming bulb for flowering during the late autumn months, and now that its cultural requirements are better understood it will doubtless become popular. It has been very good at Kew this season, and at the Drill Hall on Tuesday Messrs. R. Wallace and Co., of Colchester, showed a basket of flowering plants, and received a first-class certificate for it, an award that the plant well deserved. In general appearance it is intermediate between an *Amaryllis* and a *Nerine*, with the bold scape of the former and the prettily crimped or undulated petals of the latter flower. In its rich shade of apricot-yellow, however, it is unique. A coloured plate of it was given in THE GARDEN for January 19 of this year. To be successful in the culture of this *Lycoris*, it must be grown in a warm greenhouse, whilst a curious fact in regard to its habit in its native country (China) is that it rests entirely throughout the wet period, with the temperature at 85° and a rainfall of about 100 inches, bursting into flower with the advent of cooler days.

**Pteroma macranthum** is a most useful and showy late-flowering plant for the conservatory or warm greenhouse, and the way in which it grows and flowers in the greenhouse at Kew clearly shows that it does not require nearly so much heat as was thought necessary for it in the early days of its introduction. The plants at Kew are now superb, bearing numbers of rich violet-purple flowers, which individually must be quite 4 inches across, and they come in succession for some time. The plant is seen to better advantage when planted out and trained to the roof as at Kew, and the flowers are finer than those of pot-grown plants. In growth, too, the plant is handsome with its broad green, prominently veined, hairy leaves and woolly shoots. There is quite a host of fine flowering plants to train to our greenhouse roofs and pillars for flowering in

spring, summer, and early autumn, but when all these have had their day this *Pteroma* bursts forth in a richness and profusion of blossom exceedingly welcome during the duller days of the year.

**The scarlet Oak (Quercus americana coccinea splendens).**—Among all the bright autumn tints we have seen nothing so brilliant and lasting as are the leaves of this Oak, of which Mr. Anthony Waterer showed a large tree at the Drill Hall on Tuesday. To see it is to desire it, and one wishes that it could be increased as readily as a Willow. Every leaf of the plant shown was perfectly coloured, and although the plant was seen to disadvantage in the dull light of the Drill Hall, its effect in sunlight in the open air must be as vivid as that of the scarlet Dogwood or the Cardinal Willow when their bark is at its brightest. Most of these gay pictures of autumn-tinted leaves are of very short duration, but Mr. Waterer says that this Oak will retain its brilliant leaves till about Christmas.

#### HORTICULTURAL EXHIBITIONS.

How frequently complaints are made as to the judging at some of our horticultural shows by disappointed exhibitors is well known to most gardeners, and the statement is occasionally made that the judges looked at the cards before making their awards, or other charges are brought against them. Such statements are rarely, if ever, correct, and reflect little credit on the person bringing such a discreditable reflection on the judges. At the same time, I think it would be decidedly advantageous to remove any opportunities of having the slightest suspicion on the integrity of the judges. A great deal towards this object may be done by providing all exhibitors with their cards sealed in separate envelopes, with a number attached or written on the outside corresponding with a like number in the secretary's book. When the award is made the envelope is then opened, and the first, second, or third prize ticket affixed, as the case may be, to the exhibitor's card, and the envelope taken away at once by a member of the committee who follows the judges round, the other envelopes, where no prizes have been awarded, not being opened for the exposure of the cards until some time after the public have been admitted to the show, thus proving that no card examining has been done. By this mode it is palpable that no favoritism can be shown to any exhibitor, and a cause of complaint is removed from those who are bad losers. Very little extra expense is incurred in purchasing the envelopes for the cards and much annoyance is avoided. One thing should be strictly enforced, *i. e.*, to exclude the judges from the show until called upon to commence their duties. This is not always done, and it is certain to cause some unpleasantness if they mingle with the exhibitors prior to the awards being made. I have seen judges at a show that I formerly attended assisting their friends to stage, and also making suggestions how to improve the appearance of their exhibit. Now if the competition was very close, the same judges would, without a thought of any wrong, naturally lean towards or favour their friend's exhibit. No doubt mistakes are often made by judges, but it is not always their fault, but that of the exhibitors, who will not finish staging by the stipulated time. It stands to reason that when the judges cannot commence to act until an hour later than they should have started, they must hurry over their work to finish by the time the public are admitted; even then it is not always possible to complete the awards before opening time. Every judge who has had to go on with his duties with the public swarming around him and his colleagues is well aware how difficult it is to arrive at a just decision, as it is impossible to examine the exhibits as carefully as if free from a lot of people jostling against you. I think I have stated sufficient reasons to show that it is to the interest of exhibitors and committees that every effort should be made to finish staging at the time named

on the schedule; that it can be done is proved every year at the biggest horticultural exhibition in the provinces, *viz.*, Shrewsbury. There the tents are cleared at the appointed hour, the judges walk in at once, and the public are admitted exactly at the time advertised for the show to be open. Another matter that possibly concerns committees more than exhibitors is how to avoid having unsightly blank tables—through exhibitors not staging according to their entries, thereby spoiling the general appearance and effect. This defect is not discovered until almost the last half hour for staging, and the committee are frequently bothered to know how to fill the space allotted to disappointing exhibitors. To check this difficulty, a society (of which I am a member) inserts a clause in their schedule, that "for every entry not staged a fine of 2s. 6d. is charged," so that if a person made forty entries and only staged half that number, he would be fined 50s. This provision acts splendidly, as the committee know exactly how to arrange for the exhibits (as all the entries are usually staged); if not, the fine has to be paid, and goes towards the funds of the society. Hundreds of exhibitions will be held within the next few weeks, and I hope the above remarks may prove serviceable by preventing friction, and also giving hints to newly-formed societies. R. H.

**The weather in West Herts.**—A very cold week for October, the mean temperature being about 12° below the average for the time of year. On no night did the exposed thermometer register less than 9° of frost, and on the night preceding the 28th 13½° of frost were indicated by it. It is now five years since such low temperatures as those recently recorded have been experienced in the month of October. There occurred a little rain and sleet on the 26th, otherwise this was a dry week. All my *Dahlia*s were killed by 13° of frost on the night on the 23rd, or nine days in advance of the average date of their destruction in the previous ten years, and earlier than in any year since 1888. During October there were only four days which could be regarded as unseasonably warm, while seven were of about average temperature, and the remaining twenty days more or less unseasonably cold. The check to its growth that vegetation received towards the end of October will perhaps be best shown if we take the temperature of the ground at 1 foot deep at the beginning and end of the month. On the 1st the highest reading at this depth was 62°, and the lowest 40° on the 30th, showing an extreme range of 22°. In none of the previous ten Octobers has the range in temperature at the same depth exceeded 15°. Rain fell on fifteen days, and to the total depth of 2½ inches, which is about half an inch below the October mean for the previous thirty-nine years. At the commencement of the month the soil was unusually dry for the time of year, and is now gradually becoming dry again owing to the very slight rainfall of last week. During the past ten years there have been only two Octobers with such a deficient record of sunshine; the total amount recorded, however, exceeded that of the previous October by about twenty hours. The winds were mostly light for the season; indeed, on no fewer than thirteen days the average rate of movement of the air at 30 feet above the ground fell short of four miles an hour.—E. M., *Beckhamsted.*

"This is an Art  
Which does mend Nature: change it rather; but  
THE ART ITSELF IS NATURE."—*Shakespeare.*

## CHRYSANTHEMUMS.

### NOTES FROM RUSSIA.

DAILY I ask myself, what can I do to prevent the Chrysanthemum flowers damping? It is sad to see these beautiful flowers fading away, even before they are fully open. My Chrysanthemums are in the same house in which they have been grown for the last two seasons, and damping has never been so bad as this year. I not only find that the petals are damping on the top, but the whole interior of the calyx is rotten. I am very much disappointed. One has much trouble to get good flowers, and now, when the time comes to be compensated for the work done, there is only failure. It is of the big blooms only I am speaking; all the other varieties are perfect and not a flower has suffered from this disease. All are in the same house, and have had the same quantity and the same quality of manure. As regards the weather, we have had an unusually fine autumn. Some varieties suffer much more than others; for instance, G. W. Childs and W. Seward are damping off wholesale, or nearly so; next follow Viviant Morel, Ch. Davis and Puritan. Bouquet des Dames and Avalanche do not suffer nearly so much as the kinds mentioned.

I have observed a rather peculiar characteristic with Viviant Morel and Ch. Davis. As you know, these two varieties vary very much in the tint of colour; the former produces flowers almost snow-white and others lilac-mauve, the second clear yellow and bronzy-buff ones. The white and the yellow blooms suffer much more than the others. What is the reason? The plants with large blooms (especially those with dark flowers) have been shaded in the sunniest part of the day.

I am obliged to Mr. Shoemith for his kind and detailed answer on p. 195, and no doubt shall greatly profit by it. Most of the kinds named by Mr. Shoemith are in my possession, and the few I lack I shall add to my collection next spring.

Mr. Shoemith will excuse me for saying that I do not agree with him concerning Lady Fitzwygram. I have grown this kind for two seasons, but I have now discarded it. Of course it is a most profuse bloomer, the individual flower is good, height of plant all that can be desired, but the stalks are too weak, and all the flowers droop in the most undesirable way, as well on disbudded plants as upon those not disbudded. Many new varieties are showing this fault, and I think it most desirable to direct the attention of raisers of new Chrysanthemums to it. The growth improves, the plants get dwarfier, but the drooping habit of the flowers is on the increase, and that, I think, is a great fault. I do not doubt that Lady Fitzwygram is, nevertheless, a very valuable kind for florists, who want a lot of white blooms upon short stalks—for wreaths, for instance, where each flower is wired—but for arranging in vases where long stalks are requisite it is worthless. I have replaced Lady Fitzwygram with Mme. Gastellier. The habit of growth and abundance of flowers are as in the former; colour creamy white; the centre of the flowers built up higher than in Lady Fitzwygram, more like that of M. G. Grunerwald. But what chiefly tells in its favour

is that the flowers are borne erect, much better than in Lady Fitzwygram.

Allow me to once more call the attention of your readers to the truly charming kind, Norbet Puvrez. Though it began flowering at the end of September, I have at the present date (October 23) some magnificent specimens, grown as half, or, better still, as quarter standards. The stems measure from 12 inches to 15 inches in height, and the head from 20 inches to 24 inches in diameter, quite covered with blooms of its peculiar terra-cotta shade. A very fine September-flowering, orange-coloured, dwarf pompon is Mme. Edouard Lefort. Mme. Eulalie Morel is good, thanks to its dwarfness and colour, but, as in Mme. Gastellier, the flowers droop. General Hawkes I consider the best kind of its colour, would be better if dwarfier. What do you think of Fleur Parfait? Much has been written about Mme. Lacroix. I can do without it. Disbudded it reminds me somewhat of a small, bad Avalanche; not disbudded, it looks very poor. Ryecroft Glory is just opening for the first time with me, and I am watching the progress of this much-praised kind. The large flowering pompon Mme. Gabus I consider not worth growing; it looks very similar to my old Martinmas, but the latter is in every respect better. Mme. Gabus shows a lot of flower-buds, but only some of them open, the remaining ones being blind.

Of the pompon class, I like best the old Mlle. Elise Dordan. Snowdrop and Purity I cannot get to flower, and shall be obliged to discard them. Do you know the golden orange-coloured pompon Veuve Clicquot? Last year I was about to discard it, but then I made up my mind to give it a trial as a standard, and now this standard is simply grand. Grown in bush form, it is not worth anything, owing to its tall, straggling habit of growth, but as a standard it is first-rate, the flowers of a fine lively colour. I have now good standards in flower of Roi des Précoces, W. Holmes, and Martinmas (a little too stiff for standard work). The stems of these standards are from 30 inches to 35 inches high.

What is your opinion about the Queen of England, Empress of India, and Golden Empress of India? Do you think them really worth growing if not intended for exhibition? I get one good flower and five, or even more, bad ones. I fancy I never read in THE GARDEN about the yellow sport of Bouquet des Dames, sent out from Germany under the name Germania. It has just opened, and I consider it the best yellow Chrysanthemum of the large flowering section I have got. The growth and the form of the flower prove that it is indeed a sport from the old Bouquet des Dames, and a good one. The colour is extremely pleasing—a clear yellow hue. The other kind sent out from Germany under the name Frau Commerzienrath Gruson is a sport from the well-known La Triomphante. The colour is bronzy buff; growth, &c., like the parent.

R. KATZER.

*Pawlowsk, near St. Petersburg.*

**Chrysanthemum Ryecroft Glory.**—It would be difficult to find a more useful, showy or desirable Chrysanthemum for out of doors than the above. I have at the present time (October 18) several plants growing on a west border. They are from 4 feet to 5 feet high, nearly a yard across, and one mass of rich orange-yellow blossoms. For cutting, this Chrysanthemum is most valuable, the long stout shoots being thickly covered with blossoms.—E. M.

**Chrysanthemum names.**—Each recurring season various protests are to be found in the

different horticultural papers against the practice of giving to new Chrysanthemums the names borne by old and well-known varieties, but these protests seem to be useless, for young as the season yet is two glaring instances have already put in an appearance among the varieties that received first-class certificates at the meeting of the National Chrysanthemum Society, held at the Aquarium on October 8 and following days. The two varieties in question are Boule d'Or and Phœbus, and of these Boule d'Or was, according to the catalogue of the National Chrysanthemum Society, raised by Bernard, and sent out in 1882, while among the newer varieties enumerated in the supplement issued in 1894 a second Boule d'Or appears, so that the present one described as new must be the third. In the case of Phœbus the original variety (Japanese reflexed) was raised by Salter, and sent out by Messrs. Veitch in 1886, and now the second one puts in an appearance. This system, or rather want of a system, in naming Chrysanthemums leads to no end of confusion; in fact the nomenclature is in such a muddle, that to keep even fairly conversant with the different varieties entails more time than anyone except a specialist can spare for one class of plants. The aggravating part of the matter is that there is not an atom of excuse for such proceedings, as lists and catalogues are continually being issued in which it is easy to ascertain if the name has been in general use before.—T.

### CHRYSANTHEMUMS AT CHELSEA.

THE display of Chrysanthemums in the nursery of Messrs. J. Veitch and Sons is a large one, and the collection comprises a very complete set of this season's novelties, whilst the newer kinds of the last few years are also well represented. It is gratifying to note that, besides the acquisition of new varieties in other shades of colour, there has been a manifest reduction in the stature of the plants, and, taking them collectively, there is now a goodly number that, even when grown for large show blooms, bear their flowers at a height well within, or beneath, the line of vision. Most of the plants in the Chelsea collection carry from three to five flowers, and they are altogether an admirable lot. They not only fill the large span-roofed house usually devoted to them at this season, but so great is the number of varieties that must be grown, and of novelties to be tried by those who essay to be abreast of the times in regard to this special flower, that they are numerously distributed in other houses also. The predominance of Japanese kinds is another prominent feature of latter-day Chrysanthemum displays, and is quite as marked here as elsewhere, by far the greater number of those we noted belonging to this section. Pallanza is fine, of a rich Sunflower-yellow colour, with long florets that droop at their points, altogether a graceful and distinct bloom. M. Pankoucke is also yellow, but of a little lighter shade than the preceding, with similar long drooping florets, the plant of medium height and robust growth. Miss Louise Black is a magnificent variety, of a deep Buttercup-yellow, and beside it even Sunflower looks pale. The petals are long and quilled, and the flowers full, broad, and graceful. Mons. Ch. Molin, a reflexed Japanese, has a flower of fine depth and breadth of petal, in colour deep amber-yellow, flushed with bronze on the lower half of the petals. M. Gruyer is very fine in the shade of colour that for so long made Mme. Audiguier so indispensable, but without the tall habit of this latter kind. Its rosy flowers are very distinct and the outer florets droop considerably. Mme. Carnot appears to be a worthy addition to those having white flowers, judging from its fine character here. It has a large, full flower, the florets being long, narrow, intermingled and drooping

at their tips. *Warrior* (an incurved Japanese) has a good bloom, the inside of the petals chestnut-red, the reverse buff. *Queen of Bufts* is a pretty shade of buff flushed with bronze, and touched with a brighter shade at the base of the petals, which incurve in the centre, making a fine full flower. *Mutual Friend*, white, with long quilled petals, looks promising; and *Graphic*, also white, has a full solid, but graceful flower. *Mme. Calvat* has a very large bloom, pure white in colour, with broad petals distinctly reflexed. *Vice-President Calvat* was noted in good form and colour, rich crimson, with golden reverse. *M. Georges Biron* is a worthy addition to this class, being dwarf and free in growth, and very showy, of a bright chestnut-red, with buff-yellow reverse, the florets long and somewhat drooping. *E. Molyneux* when first sent out was a great gain in point of colour, and doubtless is the parent of the fine series that partakes of the same character, with even greater brilliancy of colour. *John Shrimpton*, *William Seward* and *G. W. Childs* are quite an indispensable trio. *Duchess of Wellington* is another superb yellow with a large bold flower, the outer petals extra long and drooping, and *Princess May*, now well known, was in good form. *Nyanza* has a fine flower of great substance, bright red inside with a reddish brown reverse, really a bold handsome kind, and *Primrose League* was noted, one plant having three grand flowers of a delicate cream-white colour and light graceful form. *Hairy Wonder* is all that the name suggests, and would appear a good grower judging from the robust plant, with several bronzy buff flowers excessively hairy. *Louis Boehmer* of this class was also well grown and finely flowered. *Eva Knowles* is distinct, the flower of tasselled lightness and rich apricot colour, with straw-yellow reverse. *Colonel Bourne* is another sterling acquisition in reds, dwarf and free, with a full, high, broad-petalled flower of a distinct light crimson, very rich and bright. *William Tunnington*, a new incurved variety, was finely represented. Its petals are broad, bluntly pointed, of a deep chestnut-red, tipped with bronze, the reverse buff. *C. H. Curtis*, which does not appear to have been generally satisfactory, was also well flowered, the blooms being large, made up of an enormous number of narrow petals, which are of a deep rich colour, but it appears to lack that perfect finish towards the centre which makes up the standard of incurved perfection. Others that we noted in fine form were *Louise*, *C. E. Shea*, *Mr. W. Dreer*, *Mrs. R. C. Kingston*, *W. H. Fowler*, and *Col. W. B. Smith*.

It might appear as though the town *Chrysanthemum* grower had no drawbacks, since it is possible to bring the flowers to perfection even in an environment of smoke, but the blooms when expanded do not last so long fresh as in the purer country air.

#### SHORT NOTES.—CHRYSANTHEMUMS.

*Chrysanthemum Clara Jeal*.—This is a stable addition to the reflexed section. It is no erect or stiff-petalled flower called reflexed by courtesy, but a handsomely formed one, colour golden buff.

*Chrysanthemum Thomas Wilkins* gave promise last season of being a deserving variety, belonging to the narrow petalled section. The blooms are well built, solid and of pleasing shape, the florets drooping gracefully at the point. The colour, a deep chrome-yellow, is pleasing.

*Chrysanthemum La Moucherette* is one of *Calvat's* fine seedlings, and bids fair to excel that favourite *Col. C. B. Smith*, for it shows not only similar form, but richer colouring. Whether it is likely to prove good as *Col. C. B. Smith* remains to be seen, as the latter has become a prominent variety in all collec-

tions. This season it has been found in good form almost everywhere.—D.

*Chrysanthemum Virgin Queen*.—This is one of the most pleasing of the single section. The petals are long and loose, the eye golden and not large. The plants bloom at a moderate height and profusely. A little disbudding improves the flowers appreciably. For the decoration of vases, &c., it is a most beautiful variety.

*Chrysanthemum Philadelphia*.—I have seen this American novelty in several collections, but in each case of a creamy hue, the petals showing a tendency to reflex rather than to incurve. Perhaps our climate does not suit it yet, and it may show that fine incurved form seen on imported flowers last year after it has been grown another season.—D.

*Chrysanthemum Mrs. C. E. Shea* was sent out in the spring of this year at the price of one guinea each plant. At that time persons were dubious about purchasing this novelty, but I fancy those who did not will regret it. The colour is a soft creamy white, with just a tinge of green in the centre, while the florets are unfolding. They are long, and entwine amongst each other irregularly. The blooms have a massive appearance without any signs of coarseness.—S.

*Chrysanthemum Phœbus*.—This must not be confounded with the variety sent out by *Mr. A. Salter* in 1886 under this name. It is of Continental origin. I have this season seen it growing under various conditions, and in all cases it was promising. It grows 6 feet high when treated in a natural manner. The blooms of the reflexed Japanese type are well formed, the florets, flat, drooping slightly at the tip, are fairly broad and evenly disposed, the colour a clear golden yellow.—P.

*Chrysanthemum Vignolo*.—This is a new and lovely single-flowered variety raised by *Mr. H. Briscoe-Ironside*, and shown by him at the *Crystal Palace*, where it attracted much notice besides being certificated. The flowers have long narrow petals, which taper to a fine point. They are of a distinct shade of rosy buff, changing at the base to a clear deep yellow, which forms a well-defined, but irregular zone around the yellow disc. It is a decided acquisition to a class that yearly grows in numbers and popularity.

## ROSE GARDEN.

### ROBUST VERSUS COMPACT-GROWING ROSES.

EVERY year it appears more manifest to me that some sort of classification is necessary amongst the Hybrid Perpetual Roses. The weak growers require to be separated from those of a vigorous habit, and I think that nurserymen's catalogues should furnish this information in a more direct manner than they do at present. Why cannot such varieties as *Merveille de Lyon* and others of the same habit of growth be classed by themselves, so that the public can tell at a glance the kind of Roses they are selecting? There should be no difficulty in separating such sorts as *Margaret Dickson* and many others, which frequently make shoots from 6 feet to 8 feet long the second year after planting. If this was done there would be no excuse for the inequality that many Rose beds and borders now present, with many of the dwarf growers in the middle or at the back, the robust growers being near the outside and overtopping those at the back.

There is a great waste of force in the plants when we have to reduce these 8 feet long shoots. To obtain the full benefit from the robust growers they want pruning on quite different lines from the others, and therefore should be planted by themselves or in the inside row. I think we are altogether wrong in planting in the indiscriminate way we now do, and as the nurserymen do not plant in that way for their own convenience, I cannot see that it would be any hardship for them to point out to their customers which are the low growers and which

are the robust ones in separate lists. We prune the strong-growing Roses too much. The long, thick shoots which they annually send up from the base Nature never intended to be slaughtered in the way they are. To prove this, we have only to peg one of them down on the ground and it will flower nearly at every joint along its whole length. I am aware it is not always convenient or desirable to have pegged-down Roses, nor am I advocating that plan. Instead of cutting the long growths down to within 1 foot or 18 inches of the ground, we should have them 4 feet long and furnish a stake for each, so as to support subsequent growth and draw it away from the middle, eventually converting the plant into a large bush. Every year one or more strong growths will rise from the bottom, while the same number of old ones may be cut away to make room for them. Only those who have seen Roses grown in this way can realise the number of flowers that a single plant will produce in one season. J. C. CLARKE.

*The Macartney Rose*.—The single white form of this Rose is worthy of a place in all gardens. I first saw it at *Funchal*, in the island of *Madeira*, in 1888, where it was climbing over a tree about 30 feet in height. The stems were as thick as a man's arm, and long flowering sprays hung downwards from the boughs in graceful festoons. Though doubtful of its hardiness, I procured a plant in 1893 and planted it against one of the *Larch* supports of a pergola. That winter, on one night, the thermometer on the Grass registered 21° of frost, and I gave the Rose up for lost, but it survived, and during the summer made a shoot about 5 feet in length, a few flowers, which did not open well, appearing in October. Last winter it was unprotected, and after the long frost looked absolutely dead. However, with the return of spring it burst into growth and threw out a number of short side shoots, each of which terminated in one or more buds. The flowers, some of which are 4 inches across and scented with a delicate ripe-Pear-like fragrance, are very beautiful, and have opened, not simultaneously, but in parties of from two to five a day, remaining in beauty for about two days and closing every evening. There has been no day since the commencement of its blooming on which two or more blossoms have not been open, and it gives promise of continuing to flower until the end of the month. The foliage, dark and exceedingly glossy, is very lovely, and sets off the white petals to perfection. The Rose is evidently quite hardy in the south-west, and should be more extensively grown.—S. W. F., *Torquay*, October 20.

*Rose Niphotos*.—As a standard this Rose is much harder than is commonly supposed. I expect few cultivators outside the western counties would think of growing it as a standard in the open air, but I can assure them that in the few instances in which it can be seen growing it is as vigorous and flowers as freely as the majority of the Hybrid Perpetuals, and when it comes to be better known that it does well as a standard in the open it will be more generally grown. I think that last winter quite settled the question of its hardiness, as I have some standards that lived through it with the buds in a dormant state. The plants have not only grown well, but they have flowered freely and been as free from mildew as any other variety. They have in fact made fine heads, and in every other respect leave nothing to be desired. It is unfortunate that this Rose should be regarded as more tender than many others of the same class, but it is so regarded by many cultivators even in the west of England. There is certainly no reason for this in the case of cultivators who reside in the western counties, and I am not sure it would not thrive in the midlands. If there are any that do not care to venture it as a standard, they may safely use it as a climber against a south wall. When so treated in *Somerset* it is very satisfactory.

There is a very healthy plant growing against the south front of Col. Serle's house at Fitzroy, near Taunton, and the only fault that gentleman finds with it is that the flowers are too large. I do not think we want any better evidence of its value as a climber.—J. C. CLARKE.

#### VERSES IN RETURN FOR A BOUQUET OF TEA ROSES.

J'ai, sur toute fleur déclose,  
A chanter l'honneur de la Rose.  
JEAN DE LA TAILLE.

Why should the fairest soonest fade?  
Dear Roses, in a golden glass,  
So frail and delicately made,  
I fear to touch you as I pass.

Here "Dr. Grill," of tender tone,  
Betwixt an apricot and peach,  
Behind a shell-like "Lambard" lies,  
A mystic sunbeam gilding each.

This "Rève d'Or" should stand alone,  
Round, filmy-white, with pink inside,  
Making creamy harmonies  
With wan "Safrano" spreading wide.

And radiant in this sunset gold,  
"Madame Berard," with stalwart stem,  
Expands her massive foliage bold,  
And half conceals a ruby gem.

But as I kiss the fairest flower,  
With petals pink as babies' feet,  
There falls a noiseless, scented shower—  
It's "Souvenir d'un Ami"—sweet!

M. C. D.

### FLOWER GARDEN.

#### MICHAELMAS DAISIES.

THE observations concerning the above useful group of perennials by the Rev. C. Wolley-Dod (p. 293) are both seasonable and highly interesting; indeed, they are valuable to all interested in these flowers, coming as they do from so close an observer. Mr. Wolley-Dod concludes his remarks with the observation that "much more might be said about the whole class and its treatment," and in this I fully agree. It is interesting also to learn that, seeing the short lapse of time since the conference, Mr. Wolley-Dod has been so successful in the raising of improvements in these flowers. It is quite true, however, that there were many good things present at the conference, and, given a selection of the best and most distinct, it would be an easy matter to raise any number of seedlings. Not altogether a haphazard gathering of all the seed heads available should be made, as this would in some degree be to little or no purpose; but with a fixed motive in view, endeavour, by careful hybridisation and selection after, to attain the desired end. For instance, suppose a desire existed for the rosy purple shades of *Novæ-Angliæ ruber*, which are considered by Mr. Wolley-Dod to be too tall; in such a case why not take *Novi-Belgii Pleiad*, a dwarf variety with bright rose flowers, and fertilise with pollen from the brightest of the *Novæ-Angliæ ruber* section. By making the former the seed parent it may be possible to get a plant of more medium height than we have in the *Novæ-Angliæ* group, and with possibly brighter flowers. The blooms so fertilised would, of course, need protecting. There are many others that may be operated upon, and by these means these beautiful plants may quickly become more beautiful. A very charming kind for beds is *Novi-Belgii levigatus*, which in the hands of the hybridist may be worth a good deal. Where a dwarf, free-flowering and compact bush is required, this is excellent in every

way, while its pretty masses of rose-pink blossoms are most effective. What appear to be most in demand are the warmer shades of rose and red, bright decisive colours that are effective at a distance. Of lavender, mauve and lilac-blue shades there are already more than enough. This is why I recommend raising seedlings more on fixed lines, otherwise, with the present preponderance of the above-named shades of colour and the unsolicited assistance of the ever busy bee, progress would be slow. Of course there are good things the result of haphazard crosses, though I have never had much success myself from numbers of seedlings transplanted.

I notice that the varieties of *Novæ-Angliæ* are too tall for Mr. Wolley-Dod, but the height of these or any other tall kinds may be in a great measure reduced if it is so desired. Many of the most beautiful kinds are too tall certainly for beds, but if any such are cut down to within 6 inches or 9 inches of the soil in the first week in June each year, all such as the *Novæ-Angliæ* kinds would flower at about 3 feet high, rather under in fact. This cutting down does not in any way mar the general flowering, and those plants so pruned bloom just as freely and less than a week later than they would had they not been interfered with. The pruning is not recommended so much for freshly planted subjects as for the more established plants. Of course there are places and positions in many gardens where tall plants are especially needed, and there are many others where dwarf kinds of these Asters, and especially late-flowering kinds, are much wanted. Many amateurs with limited space at disposal object to tall flowering plants, but by adopting the cutting-down process many of these autumn flowers should find a home in most gardens. By dwarfing, these plants are adapted to a greater variety of purpose, which should be of advantage in large gardens where spacious beds have to be filled for certain seasons. For several years in succession prior to the conference I experimented with these Asters, and found that the height was reduced about one half.

Another plant treated in the same way makes a splendid bed at about 3 feet high. I refer to *Pyrethrum uliginosum*; indeed, it flowers more freely when pruned. One year I had a bed some 40 feet long of this, and in June I cut the one half down as above suggested, leaving the other portion to attain its natural height. The latter at flowering time was fully 6 feet high and about four days earlier in its flowering, while the pruned portion was just half its usual height. The latter made a really splendid show, effective at 100 yards away, and by its dwarfness visitors could see the effect. There is good room for such plants in many gardens where only a mass of greenery exists. For instance, imagine a sloping shrubbery bank at some distance from the dwelling, and what plant have we better suited for displaying itself to advantage in such a position? It may even be formed into a floral bank by itself by pruning the plants in this way in June, and with the shrubs as a background would produce capital results.

But to return to the Asters. I note Mr. Wolley-Dod very prudently refers to selecting kinds "suited to the climate in which we live." Here in the south the whole family, with the exception of *grandiflorus*, flower well year by year. At the same time, it would be useless to recommend all the kinds for northern districts and Scotland. For the latter the *Amellus* section would prove admirable, and where strong-established plants exist, a really fine

display may be relied upon as a certainty. Though even with these, where planting is being done, I would advise early autumn rather than spring, because spring planting must produce a check which may be welcome in the south to make later bloom. Another beautiful dwarf kind and early is *acris*, with its remarkable masses of flowers, and close by in the flowering is the very charming *ericoides* which must have space to display its beautiful and graceful spray-like branches of bloom. *A. ericoides*, by reason of its gracefully arching stems, may be well suited for the rockery also. In short, it is such as this and the beautiful *Diana* mentioned by Mr. Wolley-Dod that must be seen in groups by themselves if we are to see their beauty and worth. Many of the kinds are worth good culture, and, given a fair depth of soil and room for development, will show themselves worthy of it. It is little good huddling these beautiful sorts into the shrubbery, to be forgotten and uncared for, when the flower borders are nearly devoid of blossom. Very pleasing, too, are many kinds for vase decoration, and in sheltered gardens and positions where they can receive protection from early frost, many a welcome gathering of flowers may be made till quite late in the year. Any one with only a slight knowledge of these plants may, by studying the various aspects of the different sections, speedily turn them to good account either for the shrubbery, the border, or on the lawn in open beds, and for cutting.—E. J.

— For the last few years I have taken a great interest in named varieties of Michaelmas Daisies, procuring them from many sources until I have now over eighty distinct kinds. To some the difference may at a glance be almost imperceptible, but upon a closer inspection a distinction is apparent. It is not only as garden flowers in the autumn that Michaelmas Daisies are so pleasing, but in a cut state they are also useful and much appreciated. No hardy flower that I know lasts longer in water than some of the Asters. To obtain a pleasing effect and to enjoy their beauty in the garden they should be grown by themselves, or at least they should have few associates in the shape of other flowers. To see them struggling amongst herbaceous plants generally is, I fear, all too common. I grow Asters in a border 5 feet wide backed up by a closely cut Laurel hedge and margined in front by grass. The only plants that are associated with the Asters are *Pyrethrum uliginosum*, *Rudbeckia speciosa*, *Chrysanthemum maximum* and *Anemone japonica alba*. From the middle of August until the end of October there is a charming display of flowers. Along the front of the border there are clumps of *A. Amellus bessarubicus* a yard through, alternated with a similarly sized clump of *Rudbeckia speciosa*. The rich orange of the latter contrasts superbly with the deep violet of the Aster. I have at least fifty clumps each of the two plants in combination. Those persons who have not tried the two together should lose no time in adopting the suggestion.

A few lines on those Asters that I found synonymous may be instructive to those who contemplate planting this autumn. *A. dumosus* and *A. fragilis carneus* were sent to me as distinct, but the former, no doubt, is the correct name. Undoubtedly this is one of the best of dwarf growing sorts. *Mme. Soyemuir* I received as being something quite new, but I find it exactly the same as *longifolius formosus*. *Circe* is identical with *lævis Calliope*, a free-flowering, fairly tall-growing variety. *Amethystinus* and *oblongifolius* are when fully expanded closely allied: the former when in the bud state is distinct by reason of the buds having a pink tinge of colour about them. Both in full flower at the present time are decidedly showy and free-flowering.

As to which are the best varieties of Asters is purely a question of taste, but no doubt the

small-flowered kinds, such as cordifolius elegans and c. e. Diana, are the best. The ericoides type, too, finds many admirers. In spite of the freedom of flowering of A. ericoides elegans, I think the type is more handsome. The branchlets are horizontally inclined, giving more grace to the plant than the more erect form of e. elegans. E. Clio is a dwarf-growing, much appreciated variety. With me the buds of A. trinervis have not yet begun to unfold their calyx. The pure white blossoms of A. Tradescanti are only just opening here and this is regarded as being an early season. This grows 5 feet high.

Vimineus is hard to beat where a graceful character and free-flowering habit are appreciated. Chapmani with its horizontally formed side shoots is less compact than some, but it finds admirers. I never saw such a profusion of blossom upon plants of Novæ-Angliæ ruber as this year. This is without doubt one of the showiest varieties we have. Amongst white-flowering kinds none is so good in my opinion as Novi-Belgii Harpur-Crewe. A. N.-E. polyphyllus is free-flowering and pure white, while N.-B. Snowflake and Lady Trevelyan are worthy of a place. The early flowering dwarf-growing ptarmicoides finds many admirers. A. diffusus, A. d. pendulus, and A. d. horizontalis are all worthy of attention. The two former are late-flowering, therefore valuable. One of the finest of dwarf-growing sorts is Pleiad. It grows freely, yet not higher than 9 inches, and flowers profusely. Some of the catalogues describe it as bright rose, but I find much blue in it. A. versicolor and A. v. Themis, the former tall and early, the latter dwarf and late, are remarkable for the changing colours of their flowers. A. acris is too well known to require more than a passing note; no garden could possibly be deemed complete without several clumps of it. — E. MOLYNEUX, Swanmore Park, Hants.

#### WATER LILIES AND NELUMBIUMS IN NORTH AMERICA.

MR. J. N. GERARD, writing to us from New Jersey under date October 10, says:—

Nymphaea tuberosa does not grow so far north as N. odorata. "It is, in Canada, generally quite close to the St. Lawrence, Lakes Ontario and Erie." This on the authority of Professor Macoun, of the Canadian Survey. Nelumbium speciosum is naturalised here in the fullest sense of the term. It lives and thrives in ponds in this section with no protection; its tubers are not tender, as are those of tropical Nymphaeas, for they winter out in water at a low temperature, often covered with ice, and this will ruin the tubers of any tropical Nymphaeas—as far as we know at present. I do not know how far north it is reliably stable. I think I told you that there are large plantations in Central Park, and the growth there is as luxuriant as one could wish. Where they grow Nelumbiums in city basins in the different parks they plant the rhizomes in large flat boxes as they do all Nymphaeas, and transfer them from the nursery when the weather is suitable. At this season the boxes are lifted and stored for the winter. Some of our park tanks are very beautiful in the season, and would be perfect if they were not edged with a lot of ugly colour. The N. speciosum grown here probably all came from Kew stock. I know very little about your little isle, but it seems to me you might manage enough warmth to move the Lotus, and if it once got to running it might stay with you, for it is not necessary that tubers be formed at every break. If you can start a strong tuber (9 inches to 12 inches long) with a good lead, you might plant in good soil in a box and sink it in shallow water in a quiet nook where the sun would look at it at all times.

It always pains me to read one of those notes in THE GARDEN from those who are trying to grow Nymphaeas in spring water. Marliac's large Nymphaeas are unsurpassed; albidia, Chromatella, carnea, rosea and sulphurea are all perfect; still, if I grew but one white, it should be N. a. candidissima, as it will give many more flowers than N. albidia. I do not care much for Marliac's small

ones beyond N. Laydekeri, as to whose parentage I cannot but think Marliac is mistaken. If it is not from N. sphaerocarpa, it is a strange evolution.

The garden is dust-dry and not very inviting at present. Our first hard frost is about due, after which we shall have charming weather and the glories of changing leaves.

#### AUTUMN FLOWERS IN YORKSHIRE.

The following plants were in flower in the rock garden and open border at Holden Clough on October 16, 1895:—

Achillea argentea	Hippocrepis comosa
Aceana Novæ-Zelandiæ	Illicium aurantiacum
Anemone japonica	Hypericum androsænum
vernalis	prolificum
Antirrhinum glutinosum	Iberis gibraltaria
Artemisia echinoides	Ionopsidium acule
Asters, various	Jasminum nudiflorum
Aubrieta purpurea	Kerria japonica
Calamintha grandiflora	Lilium au atum
Cerastium Biebersteinii	Linaria alpina
Campylosiphium hirsutum	Anticaria
mollis	Cymbalaria maxima
muralis	Linum flavum
pusilla	Lithospermum prostratum
sibirica	Lobelia cardinalis
Centaurea montana	sybillitica
Chelone barbata	Lonicera sempervirens
Lyonii	Lychnis maritima
Chrysanthemum atratum	pyrenaica
Clematis erecta	Malope grandiflora
coccinea	Malva moschata
crispa	Mecanopsis cambrica
Jackmanni	Menziesia polifolia
Convolvulus mauritanicus	Mesembryanthemum
Coreopsis lanceolata	Moutbretia crocosmiflora
Corsican Daisy	Nepeta Mussini
Cornilla iberica	Omphalodes verna
Corydalis lutea	Phlox reptans
ochroleuca	subulata
Crocosmia aurea imperialis	Physostegia speciosa
Crocus	Polygonum Brunonis
Colchicum autumnale	vacciniifolium
Dahlia, various	Primula acaulis
Dianthus frigidus	capitata
Digitalis grandiflora	Salvia patens
Epilobium alpinum	Saxifraga Fortunei
Erica citiaris	Scabiosa caucasica
Erodium Manescruvi	Spirea Bumalda
Erythraea centaurium	Symphandra Hoffmannii
Escallonia microphylla?	Thymus comosus
Gentiana asclepiadea	Tritoma corallina
Geranium balkanicum	Macowanii
sanguineum	Uvaria
Geum reptans	Tropeolum speciosum
Gladiolus, various	Verbascum phonicum
Gypsophila repens	Veronica prostrata
Helenium nudiflorum	Viola cornuta
Helianthemum lunulatum	odorata
Heliopsis, various	Vinea major

R. MILNE-REDHEAD.

Holden-Clough, Clitheroe.

**Tritoma Uvaria.**—In front of the dwelling-house at Kitmoaks, the seat of Mr. E. H. Liddell, I lately saw a remarkably fine plant of this Flame Flower. I counted fifty flower-spikes, many of them 5 feet high. Such a specimen clearly shows the value of a suitable site. The plant in question was about 10 feet from the wall on the south-west side of the house.—E.

**German Irises in flower.**—We have a great many German Irises flowering at the present time, and very singular it is to see their showy blossoms produced at this season of the year. This freak is doubtless owing to the abnormal weather we experienced towards the end of the summer and early in the autumn, for I never remember them behaving in this way before. The flowering in our case at least is limited to the blue and purple varieties, for none of the yellows or browns have produced an autumnal crop of blossoms. The display of Iris blossoms at this season of the year has usually been limited to Iris stylosa and the earliest flowers of I. alata. It is, however, not at all likely that they will behave in a similar way again. One undoubted merit that may be claimed for the different kinds of Iris, is that they maintain a display of bloom throughout the greater part of the year, for, with

those above enumerated now flowering, the autumn is not without their brightly coloured blossoms, and quite early in the spring we have some members of the tuberous-rooted section, such as I. persica, I. reticulata, and its allies.—H. P.

#### NOTES ON HARDY PLANTS.

**Aster Combefishacre.**—This is one of the smaller-flowered Michaelmas Daisies, which, notwithstanding the sameness which essentially prevails throughout the Starworts, has a somewhat novel effect when in full bloom. It occurred in the garden at the place after which it is named by the owner, Mr. T. H. Archer-Hind, and belongs to the diffusus group, but has left the typical form further than any that has yet been recognised in cultivation. From the florist's point of view it is simply charming; the flowers are round, full, and profusely borne, and of a shining rose colour. It is perhaps the touch of carmine that imparts the lovely glow to the compact mass of flowers that marks it as a new and desirable variety. Its beauty when at its best was only equalled by its unpromising aspect for a week or more as its heads slowly developed. But it is so with most of these Asters, and the proper way is to wait until the plants are strong and the flowers well out before we condemn them. The stature of my specimen is 3 feet, grown on a sunny bank. I shall certainly include this in my best fifty as known to date.

**Ostrowakia magnifica.**—In reply to Mr. J. Rankin (p. 292), it is quite normal for this plant to grow quickly and early and then die down. If the roots were not strong enough to flower, as seems to have been the case, the period of greenness would be still shorter. I have had plants quite sere in June. There are many points of interest about the roots of this species both for the botanist and nurseryman. I am glad that Mr. Rankin has proved the roots quite hardy. Flowering plants grow 15 inches to 20 inches high.

**Sobolewskya clavata.**—Struck with the pleasant refreshing smell of the roots of this crucifer when repotting it, I ventured to taste them, and the flavour was most agreeable, pungent, and inviting one to eat it freely. The roots of this plant are long and of a thickened character much below the crown; they run just under the surface, too, and the thick parts arch upward and become foliated, much in the same way as (E)nothra speciosa.

**Shortia galacifolia.**—I do not think that there are two forms of this to be distinguished by the green foliage and the deep purplish bronzed leaves, and I have had many hundreds of it for some few years. I believe it is entirely a question of exposure or shade. It may be well to note the fact that the mode of culture with shade finds favour with many, because the leaves and flowers may so be got somewhat larger and perhaps faster. Still, you do not get the fine feature of rich bronzy foliage to the same extent as you get with more exposed plants; neither is the shade essential on the score of want of hardiness. The plant is quite hardy, as tested in several positions here last winter. I based my statement that the bronzy leaf colour depends entirely on exposure to light on what occurred here this summer. A two-light frame was full of this plant. All the plants were treated as to soil and everything else just the same, only, to air the frame, one light had been taken entirely off the one half and placed over the other light, so that one half of the plants had two lights over them and the other nothing. The results were that in a very short time the fully-exposed plants rapidly assumed a fine mahogany tint, while the others remained quite green and were taken by experts for Pyrola. Then I took off the lights entirely, and now within a shade the whole batch is alike bronzy. Another lot near a west wall proves the same point. Close under the wall the plants are green, but gradually as they extend from the shadow of the wall they are more bronzed.

J. Wood.

Woodville, Kirkstall.

## ASTILBE LEMOINEI.

UNDER the generic name of Astilbe I shall include quite a group of plants which have a perennial root-stock, herbaceous stems, deeply-cut leaves, and large, branching flower-clusters composed of a multitude of small white or pale pink flowers, which are individually insignificant, but in their massed aggregate remark-

*Astilbe rivularis.*

ably effective. These plants appear to be related to the Spiræas of the Aruncus section, and, accordingly, many of them have been for a long time commonly grown under the name of Spiræas, while botanists have given them the generic name of Hoteia. My opinion is that they should all be legitimately classed under one genus, viz., Astilbe, since most of them have afforded indisputable proof of relationship by the readiness with which they intercross with one another. Moreover, in the first place, the name of Spiræa should be entirely dissociated from these plants. The Spiræas belong to the natural family of the Rosaceæ, and their flowers are characterised by the presence of numerous stamens and a pistil formed of three to five carpels, which are usually free or non-adherent to one another. The Astilbes, on the other hand, belong to the family of the Saxifragaceæ, and their flowers have from five to ten stamens only and two carpels, which are generally adherent to each other, at least at their base.

The genus Astilbe was founded on *Astilbe rivularis* (Hamilt.), a perennial plant, native of Nepal and the temperate regions of the Himalayas from Cashmere to Bhotan. This species has creeping rhizomes and large radical leaves, which are biternately divided into deltate sections and have the leaf-stalks furnished with numerous tawny hairs. The flowering stems, which attain a height of nearly 5 feet, bear a few alternate leaves and terminate in a large paniced cluster of numerous small flowers. In these flowers the corolla is wanting, and the

lobes of the calyx, four or five in number, are of a yellowish-white colour, the eight or ten stamens being pure white. This species enjoys a half-shaded position in cool sandy soil, and may be advantageously planted on water-margins. In frosty weather it should be protected by a mulching of dead leaves or other litter. Under the name of

*ASTILBE RUBRA* (Hook.) a species was introduced more than forty years ago from the mountains of Khasya, in the north-east of Bengal, where it was discovered by Griffith. It was sent to Kew by Messrs. J. D. Hooker and Thomson, who found it in flower at altitudes of from 5000 feet to 6000 feet. It is distinguished from the preceding species by having five pink petals, forming a star-shaped flower, and by the abundance of stout red hairs which bristle over the stems, the leaves, and the flower-clusters. It is also known by the name of *Astilbe rivularis rubra*. This species also should be protected from the damaging effects of severe frost.

*ASTILBE DECANDRA*, an American species, was introduced into England in the year 1812. Like the preceding species, it resembles *Spiræa Aruncus* in habit. Its large biternate leaves have a glaucous tint, and its flowers, which are produced in branching panicles, are white.

*ASTILBE CHINENSIS* (*A. odontophylla*) was introduced a few years since from China, but does not appear to have in any degree come into general cultivation, as it is not mentioned in any of the horticultural catalogues. This plant seldom exceeds 2 feet in height; its leaves are triternate and its flower-clusters are white with purplish reflections. It may perhaps be a variety of the following species.

*ASTILBE THUNBERGI*, Miquel (*Hoteia Thunbergi*), was introduced from Japan fifteen years since by Messrs. J. Veitch and Sons, of Chelsea. It is a handsome species with very graceful foliage, the long-stalked leaflets of which are oval in form, and covered, as is the entire plant, with small silky hairs. The flower-clusters, composed of white flowers, changing to pale pink, and elegantly disposed at intervals along the flowering branches, are branching and stand quite erect. Everybody is acquainted with

*ASTILBE JAPONICA* (Miquel), more generally known as *Hoteia japonica* (Morr. and Desne.), and also as *Spiræa japonica* (Hort.). This species has the lower part of the stems and leaf-stalks covered with long brown hairs; the radical leaves grow in tufts and have trifurcate leaf-stalks and elongated oval leaflets almost coriaceous in texture and of a deep green colour, with a glistening upper surface. The flower panicles are erect and branching, and the bracts, pedicels, calyx, corolla and stamens are all pure white. For forcing this plant is very extensively grown, but it is also an open-air perennial of the first order, and thrives in heath-soil and in cool, moist soils generally, especially when the position is half shaded. The rhizomes are perfectly hardy, but the young shoots are often cut off by spring frosts. Several other varieties of *A. japonica* are in cultivation. The first, in the order of their raising, is

*A. JAPONICA FOLII AUREO-RETICULATIS* (about the year 1871), the foliage of which is green, variegated with yellow on the veinings of all the leaflets, and the flower-clusters are more tufted and compact than those of the ordinary type. Then there is

*A. JAPONICA FOLII PURPUREIS*, the leaves of which are of a glistening bronze colour (at least in the earlier stage of their growth), which changes to deep green as they become more fully developed. Lastly we have

*A. JAPONICA COMPACTA MULTIFLORA*, a variety

which has recently made its appearance in commerce, and which will undoubtedly supersede the ordinary type, for all the uses of which it is better adapted. Its foliage is more compact and abundant, and its flower-clusters are larger and more branching, presenting the appearance of white feathery tufts. This variety seems to have originated in a plant of *A. japonica foliis aureo-reticulatis*, the foliage of which had reverted to the normal all-green colour, while the panicles of the variety, which are also more compact, would have derived an accession of vigour from the return of the chlorophyll, and thus become increased in size and number.

The year 1879 was marked by the first appearance of a new species to which the most diverse names have been attached. At that date Mr. Wm. Bull, of Chelsea, the introducer of the plant, exhibited it under the name of *Spiræa nivosa*. In the following year he showed the same plant under the name of *Spiræa Aruncus astilboides* (a name conferred upon it by the botanists at Kew), or simply *Spiræa astilboides*, under which latter designation the plant soon became popular. Maximowicz, who discovered this species in Japan, separated it from the

*Astilbe Lemoinei.* Engraved for THE GARDEN from a photograph sent by Mons. V. Lemoine.

*Spiræas* and named it *Aruncus astilboides* (Maxim.). But the *Aruncuses* are also *Spiræas*, and all the characteristics of the plant in question bring it close to the *Astilbes* or *Hoteias*. If we adhere to the specific name, which, perhaps, is now too widely established to be altered, the plant should be named *Astilbe astilboides*, which after all is not more ridiculous than many existing botanical names, such as *Dracæna*

Draco, *Ervum Ervilia*, *Specularia Speculum*, &c. More consistent with the facts of the case and less open to objection would be the name *Astilbe aruncoides*, and this only wants the sanction of some botanical authority to secure its acceptance.

**ASTILBE (SPIRÆA) ASTILBOIDES** attains a height of from 20 inches to 2 feet. Its pinnatifid leaves have reddish leaf-stalks and oval, pointed, deeply-toothed leaflets of a brownish-green colour. The branching flowering-stems are covered with small white flowers, which are closely set, and are each formed of a tubular calyx with five white lobes, a corolla of five white petals with ten white stamens and two united carpels. This species, valuable as an open-air perennial, does best in sandy soil and is particularly effective on rock-work, but is chiefly desirable for pot culture and forcing, by means of which very handsome flowering specimens are obtained. The origin of a variety which its raiser, M. Desbois, of Ghent, named *Spiræa astilboides floribunda*, is recorded in the *Revue de l'Horticulture Belge* of 1881 (p. 145). Mons. F. Wiot, of the firm of Jacob-Makoy and Co., of Liège, one day pointed out to M. Desbois a speedy method of multiplying *Astilbe (Spiræa) astilboides*, viz., by sowing the seed. Acting upon this information, "I sowed the seed," says M. Desbois, "in the month of March. After the seedlings came up I soon discovered that their foliage was of a deep green colour, somewhat similar to that of *Spiræa japonica*, instead of exhibiting the metallic brown tint of the type. In the following spring I was struck by the great difference between the characteristics of my seedlings and those of the type, and was still more so when I viewed with admiration the fine thyrus-like flower-clusters of my seedlings, excelling those of the type in being better furnished and more numerous. I consequently considered myself justified in believing that I had obtained a new variety." M. Desbois was under the impression that his variety corresponded to the specific type of *Astilbe (Spiræa) astilboides*, and that the plant which was originally introduced under that name was an inferior variety of the same type. I, on the contrary, am of the opinion that his plant was a natural hybrid between *A. japonica* and *A. (Spiræa) astilboides* growing, probably, not far from each other in his garden, and so readily capable of being hybridised by the various kinds of insects which are continually frequenting these flowers. I hold this opinion for two reasons: Firstly, because the seedlings of *A. (Spiræa) astilboides* raised from seed sold by MM. Jacob-Makoy and Co. were exactly similar to the type, and, in the second place, because I have artificially crossed *A. japonica* with *A. (Spiræa) astilboides*, and thereby obtained all sorts of intermediate forms, many of which are very fine and superior to both parents. The chance hybridisation which I have just suggested is therefore possible.

As these last-mentioned varieties have not yet been sufficiently studied and are still unnamed, I shall say no more about them at present, and shall conclude my observations with a few words on another hybrid, *Astilbe Lemoinei*, the raising of which serves to corroborate the proposition advanced above, namely, that *Astilbe Thunbergi*, *Hoteia japonica*, and *Spiræa astilboides* are all only species of the same genus, and should be all classed under the generic name of *Astilbe*. I have never succeeded in an attempt to fertilise *Astilbe (Spiræa) astilboides floribunda* with pollen of *Spiræa Aruncus*—another reason for separating the former plant from the *Spiræas* and for rejecting the classification of Maximowicz. The following is a description of

**ASTILBE LEMOINEI:** Foliage very elegant, about 20 inches high; leaf-stalks long, branching; leaflets broadly oval, dentate, crimped, furnished with hairs, of a very cheerful green colour and satiny appearance. Close to the summit of the

foliage are the broad flower panicles with stout stalks, bearing plume-like clusters of flowers and about 20 inches in length. The flowers, which have five white petals, ten pink stamens, and two carpels, are exceedingly numerous, and, viewed in the mass, present the appearance of white plumes slightly suffused with pink. Placed side by side with a plant of *A. (Spiræa) astilboides floribunda* the new variety is seen to be twice as tall. Its period of flowering is intermediate between those of the two parents, and it commences to bloom in July, a few days before *A. Thunbergi*, one of the latest-flowering of the genus. Lastly, *Astilbe Lemoinei* is perfectly hardy, and can be as readily forced as *A. japonica*, to which it is superior in every other respect.

EMILE LEMOINE.

#### FLOWER GARDEN NOTES.

THE suggestions made last week as to the first arrangement of herbaceous borders or the replanting of the same—operations that should be put in hand as soon as possible—had reference to the general character of the work, and I should like to supplement this by a list of a few families that will be found acceptable for the purpose. It may be noted in passing that it is on those families that are represented by many varieties that one has to rely to supply a display for large borders, rather than on the more rare species that, as a rule, are often not over-robust, and, as a consequence, do not hold their own well with stronger things. The question of soil must be a primary consideration, and it may be taken for granted that anything that will grow vegetables well will do admirably for the majority of herbaceous plants. Naturally, old borders get exhausted after a few seasons, many herbaceous things being gross feeders, and evidence of deterioration in the plants the preceding summer should be the signal to work in a supply of fairly good manure at the replanting, whilst heaps respectively of heavier and lighter soil may be in readiness to work in for the benefit of those plants that are likely to require them. In the case of new ground the soil should be bastard trenched, and a good coating of manure placed between the two spits.

**TUFTED PANSIES.**—Free-flowering varieties of good constitution are what one requires when used occasionally on the herbaceous borders, special colours not being so much a consideration as in the formal garden, and bushy compact sorts may be chosen in preference to those of straggling habit. Once planted, they will, if required, stand for several years, but I prefer annual planting. Individual flowers are considerably larger, and, in addition, the young plants not only come more quickly into flower, but stand better given a hot, dry summer.

**PINKS.**—If cuttings of these were inserted at the right time in suitable soil, they will be grand plants for present lifting. For the purpose under consideration, it is not necessary to grow many sorts—*Anne Beleyn*, *Ernest Ladhams*, and *Her Majesty* are good in their respective colours. The same remarks apply to Carnations, some four or five good sorts that can be guaranteed to stand well and to furnish a mass of flower being decidedly preferable to a number of varieties whose reputation for hardiness and as free bloomers is not of the best. I suggested the other week in connection with the old *Crimson Clove* that where this variety was liable to be affected by disease *Murillo* might be substituted, but since writing this I have noticed that Messrs. Laing and Mather, of Kelso, announce that *Uriah Pike* stood out with them all through last winter, and that, too, with the thermometer several times below zero. No finer crimson variety than this can be found among the hardy border sorts, and the above statement coming from Scotland will doubtless be answerable for the outdoor planting of *Uriah Pike* in considerable quantities. Other plants that may be used along the front part of the border in connection with those above named are the dwarfier forms of *Campanula*, *Veronica*, *Iris*, and *Antirrhinum*, all of easy culture and certain to

do well and flower freely. In the matter of *Campanulas*, Mr. Meyer's able and exhaustive article in a recent issue, together with the very interesting illustrations, comes at a very opportune time, enabling one to make accurate selections from this beautiful family for the many different positions they are qualified to fill. It was noted lately in connection with *Pyrethrums* that the single varieties are most in request for cutting. For a general display, however, on the borders, it is probable that the doubles are best, and some very beautiful things are now available in these plants in seven or eight different shades of colour. The foliage of *Pyrethrums* is quite an interesting feature on the borders, and may be kept green and fresh throughout the season by a careful removal of anything looking at all brown and the worse for wear, allowing the young growth to quickly develop. If any planting is to be deferred until the spring, arising from the necessity of propagating new varieties that are somewhat scarce, spaces in the border can be reserved for their reception, the ground being prepared at the autumn planting. With few exceptions this spring planting will consist of those subjects that occupy the central portion of the border, and will include the dwarfier section of *Phloxes*; also *Pentstemons*, which will go well with *Iris*es, perennial *Gaillardias*, some of the *Lychnis* family and the dwarfier *Starworts*, all of which may be planted at the present time. The number of tall herbaceous plants is great, the only drawback being that with few exceptions they are autumn-flowering; this section should therefore be relieved by *Delphiniums*, by occasional clumps of *Lilium candidum*, *Anchusa italica*, and other earlier-flowering plants.

**POTTING UP HARDY PLANTS.**—The advisability of growing a goodly collection of hardy plants in pots where glass accommodation is somewhat limited has been before advocated, and the exceptional merit of such things for such work is undoubted. They may be potted now at any time; a compost that will suit most of them should consist of two parts light loam to one of leaf soil. They may be packed for the present tightly together in a cold frame, the pots resting on a good bed of ashes, some Fern or material of a similar nature being worked in between the pots to preserve them from frost. The varieties of *Pinks* given earlier in these notes, such as *Carnations* as *U. Pike*, *Countess of Paris* and *Mrs. Miller*, some of the *Campanulas*, *Tiarella cordifolia*, the improved varieties of *Lobelia fulgens*, *Montbretias*, *Gypsophila*, and some of the *Funkias* and dwarf *Starworts* rank among the really good things for pot work. They want careful attention as soon as they begin to move in the spring, and with the pots full of roots should receive weak manure water twice a week to keep the foliage right and to develop flower-spikes properly. If *Daffodils* are wanted in pots they should receive attention at once if not already done, a good batch being very acceptable pending the opening of outdoor flowers. If wanted principally for cutting, the early-flowering sorts will be most serviceable, otherwise a selection of good varieties for successional display can be made. If any of the above things, other than the *Daffodils*, are likely to be required for another season, it is advisable to set apart a small border for them and propagate at the proper time. It is not always convenient to lift things for the purpose from the mixed borders.

E. BURRELL.

Claremont.

**Pyrethrums: spring planting.**—Many herbaceous *Pyrethrums* planted last autumn died off during the intense frost of January and February. I made a new bed, which was sadly crippled. On mentioning it to a friend who, by the way, is most successful in the culture of these flowers, he told me I had made a great mistake in planting in autumn. Even in winters far less severe than last many plants die off simply because they are lifted at the wrong time of year. Transplant in February or March. Do the work carefully, and 95 per cent. of the plants will

live, and if fairly strong will produce many flowers the first summer. As I find them invaluable for cutting and long-lasting when placed in water, I intend renewing the beds, acting on my friend's advice and planting in spring. Perhaps these remarks may prove useful to some who have hitherto been unsuccessful with these flowers and to intending planters, especially where the soil is heavy.—J. C.

## ORCHARD AND FRUIT GARDEN.

### DAMSONS.

It is some years ago since there was such a heavy crop of Damsons as this season, and it is possible there never was such a general big crop, with the consequent result—low prices, and the cry that the supply exceeds the demand, and that Damsons are an unprofitable crop. Such a statement is open to dispute, because in bountiful years like the present one, while some growers are at a loss by their Damsons, others make a moderate profit, though quite as far removed from good markets. It is always advisable when there are prospects of heavy crops of any kind of fruit to make some arrangements beforehand for the disposal of the same and take extra care in picking, packing and putting them on the market in the best possible condition. Those who have done this have not much cause for complaint with their Damsons. Prices, of course, have been low, but, considering the glutted markets, they have been rewarded for their labour by the enhanced value of the fruit. One large grower well known to me had many tons of fine Damsons that he had gathered before they became fully ripe, packing them carefully, and which realised £4 10s. per ton put on rail. This price paid fairly well, as there was no freight or commission charges to deduct, and as the trees were on Grass land, cultural expenses were very light. Another grower was offered £7 per ton for all his Damsons a few weeks before they were ripe. The offer was somewhat indignantly declined, as not being good enough. I saw a quantity of the same fruit when ripe sold by auction at 50s. per ton in one of the northern markets. Out of this had to come carriage, portorage and

commission, leaving absolutely nothing for the sender after deducting cost of picking, cartage, &c. One of the greatest causes of these disappointing returns is the want of judgment in selecting markets and the unsuitable packages in which they are sent. There are certain markets which have come to be looked upon as the best and likely to take an inexhaustible supply; the result is they become glutted, while other towns of less repute are inadequately supplied. Packages play an important part in the value of Damsons; the half sieve and half flat are decidedly the best, as many householders will gladly purchase one of these small packages, which contain from 24 lbs. to 28 lbs. of fruit. As it is, many of the packages contain 56 lbs. and upwards each, and can only be bought by buyers who require large quantities.

Fruiting branch of the old English Damson. From a photograph sent by Mr. F. Kammell, Sittingbourne.

Not only so, but the fruit travels infinitely better in smaller packages, as the fruit does not heat or become crushed by its own weight, as it does in greater bulk.

No doubt there are some varieties of Damsons planted, or rather grown, that are practically useless for market as compared with some of the larger sorts. In North Staffordshire, Derbyshire, Nottinghamshire, and adjoining counties, some of the finest Damsons I have ever seen are grown, the variety finding most

favour and usually met with being the old English Damson. Every farm and cottage in many villages has a few trees; in some cases the hedgerows are well stocked with large well-grown trees that bear immense crops. No pruning is done unless a branch dies or breaks with the weight of fruit, and the fertility is kept up by the cattle and horses that go under the trees for shade, leaving a good deposit of droppings behind them. When I lived in Derbyshire and Staffordshire I have heard many a farmer and cottager boast of having picked so many "strikes" (the local term for bushels) from such a tree, or from such an orchard, and sold them at a good figure. In some of the smaller holdings Damsons mean a good deal to the tenant by helping to pay the rent. As a hedge tree for profit, I think no fruit-bearing tree will approach the Damson, more especially in the midlands, as it succeeds so admirably, and produces good average crops that are easily sold to men who come round to buy for large consumers. The illustration is a good type of the old English Damson. Speaking from many years' experience of the variety, I question if any other sort will equal or surpass it as a standard in the open or in the hedgerows. The fruit is rounder than that of the King of the Damsons, though quite as large and heavy. Shropshire Prune, Crittenden, and King of the Damsons are all excellent varieties, the last especially adapted for bush culture, as it bears fine large, deeply-coloured fruit in a comparatively short time after planting, and forms a good break to the wind for other fruit trees.

I should scarcely recommend the planting of Damsons on an extensive scale alone as bush trees, but, as stated, they are splendid nurses for Apples, Pears, or other fruit trees, and will also pay for attention and good treatment generally. Another advantage is that all the eggs are not in one basket; if the Damsons fail one year the other crops may not, or if the latter do fail the former may be a success. Evidently some of our forefathers knew fully as much as we do on some points in fruit culture, as I could point out many orchards in the counties named that have a broad belt round the outskirts of Damson trees which have borne good crops, selling at £1 per strike or bushel in some years, while the Apple crop has been *nil* in the same orchard. Soil and situation appear to be of much less importance with the fruit under notice than any other kind, as it succeeds more or less wherever planted. Of course, the more fertile the land, the results are correspondingly good, but even on thin poor soil a great deal of assistance can be given by mulching with rich, partly decayed manure, also by applying sewage or liquid manure in the winter months. The effects of this stimulating diet are most marked in the healthy vigour of the trees and large fruit produced. Insect pest attacks are also reduced by this liberal treatment, as it is a well-known fact that these enemies always prey upon a badly-fed and weakly tree far more than upon one that is strong and vigorous, and I can confidently advise anyone that has been troubled with aphid or red spider on his Damson or Plum trees to increase the quantity of plant food to the roots, and spray the whole tree or trees with one pound of caustic soda and one pound of crude potash dissolved in hot water, and applied warm to every shoot, branch, and trunk now while the trees are dormant. This preparation will thoroughly cleanse them from all mossy substances and also dislodge and destroy immense quantities of eggs deposited on the trees.

W. G. C.

## NECTARINES ON WEST WALLS.

A FEW years ago I planted half a dozen kinds of Nectarines on a west wall, thinking that on such a position it would be well to rely upon riders. I planted these a fair distance apart, with a dwarf, fan-trained Peach between each. The third year after planting most of these dwarf trees had to come away to allow the upper branches of the Nectarines more room. The soil being light and the trees on a sloping bank, much water is required during the summer, but to this cause and heavy mulching I attribute my success. The trees were allowed to grow freely, even strong lateral breaks from the large shoots were tacked in, with the result that a large space was quickly covered. Before the Nectarines were planted, Cherries had been grown on the wall, but owing to the border being so much drained, the trees flagged in hot sunshine and the fruit soon shrivelled. The position seems to suit the Nectarines, as there is no cracking, mildew, nor canker, and the wood at this date is almost equal to that under glass. I find with free extension we have no disease, there is no trouble with fly in the spring, and kinds can be grown on the west aspect which now occupy the south. By timely pinching of the shoots and regulating the crop, the wood is well ripened. Crowding of the tender wood of the Peach or Nectarine is the forerunner of mildew, green fly, and other diseases. I am of the same opinion as "E. M." (p. 303) as to the improved culture of late and the increased interest in Peaches, and I would add Nectarines also. I admit in some soils cracking of the fruits before they are soft is a great objection to the culture of Nectarines and Peaches in heavy clay land. Much may be done in the way of raised borders, planting standards or half standards so as to get the full benefit of the wall, and when planting, draining freely with brick rubble. Use the knife sparingly at the start, relying upon pinching to regulate growth. Of course, 1893 and this season have been exceptional years as regards warmth, but in 1894—a less favourable season—the trees fruited grandly and made good, firm wood. The varieties I tried were Advance, Early Rivers, Dryden, Spencer, Humboldt, and Pine-apple, with the older Lord Napier. All did well on the aspect named, thus proving their value for outdoor cropping. Though one or two trees have made less growth than others, all did well as regards quantity and quality of crop. G. W.

**The Nectarine Peach.**—Those who can give this variety of Peach an unheated house or merely glass protection will find it one of the very best for late work. I admit it is not one of the largest late Peaches, but it is much above medium size, and when it is luscious, brisk, vinous flavour is considered, it is superior to many of our later varieties. The fruits are pale-coloured, with a smooth skin, hence its name. In a glass case it will furnish the early September supplies. On the open walls in a favourable position I have gathered good fruits early in October. For outdoor culture I do not advise planting it largely. The tree is hardy and free of disease when well treated. Of late years I have seen fewer dishes of this excellent variety. In the north it was a great favourite grown as advised.—W. M.

**Gathering Pears.**—Pears are often spoilt by premature gathering, for I observe a great many of those sent to market are more inclined to shrivel than to ripen. Many really good sorts of Pears get a bad name through being gathered too soon, so that they remain tough and shrivel, when they would have ripened up plump and juicy if allowed a week or more on the tree. There is not so much danger of making a mistake with the very early

kinds such as Jargonelle, Williams' Bon Chrétien and others that are fit to eat a few days after plucking from the tree, but the case is very different with varieties such as Winter Nelis, Beurré Rance, Knight's Monarch and others that may be called winter Pears that must be in the store room several weeks before their proper season of ripening. I am well aware of the temptation to gather the fruit if it is grown on open trees, for rough gales blow them off and small birds peck holes by the stalk. On walls these valuable fruits ought to have a fish-net placed over them in October, when they are rendered safe from wind, birds and the slight frosts we get during that month. A week or ten days' exposure on the trees makes all the difference between ripening and shrivelling.—J. G., *Gosport*.

**Pear Van Mons Leon Leclerc.**—This is an excellent Pear and worthy of more extensive culture. Unlike many of the large sorts, it has a most refreshing and pleasing flavour. What is more, it does not go rotten in a week after it is gathered, a failing only too common in November-ripening Pears. If grown on a west wall it will hang a long time, as it is slow in coming to maturity compared with such sorts as Marie Louise, Thompson's and others. I have seen a fruit over a pound in weight in Essex and Suffolk, the finest dish I ever saw having been exhibited at Ipswich some years ago. I find the tree rather slow in coming into bearing, but when once it makes a start it yields more or less annually. It requires a wall even in the most favoured counties.—J. C.

**Plum Reine Claude de Bavay.**—In a recent issue, Mr. Young mentioned this Plum, and stated that it had ripened well with him this season. Its tardiness in ripening is its one great drawback, otherwise it is a Plum of exquisite flavour and fine appearance. It is next to useless trying to ripen it in midland counties, and even in the south of England it is often disappointing except on very warm walls. It is, however, just the Plum for an orchard house, as on well-ripened wood fruit sets freely and is not subject to dropping at stoning time. The finest crop of Reine Claude de Bavay I ever met with was on a pot tree, which was grown in an ordinary span-roofed greenhouse until the fruit had stoned, after which, being wanted by a special date, it was placed in a Cucumber house to finish. The manner in which the fruit there swelled proved plainly that it was a heat-loving Plum.—J. C.

**Apricot Hemskirk.**—Apricots fail so often, that any variety which sets freely is worth a note at the planting season. With me Hemskirk of late years has taken the place of Moorpark, a variety noted for its splendid quality, but, unfortunately, one of the least reliable. As it cankers so badly, one can rarely get a full-sized tree without losing a large portion when least expected. I admit there are large trees of Moorpark in various parts of the country, but they are rare. Hemskirk does not thrive in all soils, but where Apricots do fairly well it is one of the best, and I find it is hardier than Moorpark. Hemskirk is a large Apricot, early, very juicy, with a rich flavour. This variety grown on a west aspect with raised borders loses very few branches.—S. H.

**Trays for storing fruit.**—At a recent meeting of the Royal Horticultural Society the fruit committee awarded a silver Banksian medal to Mr. H. C. Orr, Bedford, for his patent storing trays for fruit. In a season like this when fruit is so plentiful it is an excellent invention. Each tray holds half a bushel in a single layer, and is made of light wood, each fitting one on the other, so that they may be placed to any height, remaining firm and allowing a free circulation of air all round. The shelves, made of strips of wood at the bottom, are light, and admit of the fruit drying freely. The trays could doubtless be improved upon if they could be drawn out separately. Now each tray has to be lifted off before the under one can be examined. For places where space is an object these fruit trays

will be found most useful. They are admirable for seed Potatoes when the fruit is over. Stored in these the sets will be ready for planting and in nice condition. There are other purposes to which they may be applied, and they may be occupied at all seasons of the year.—G. WYTHES.

\* \* \* Are not these trays the same as are used by our large Daffodil growers for storing and drying their bulbs previous to replanting? The trays used for this purpose are well suited for fruit storing when not otherwise employed.—ED.

## PEACHES IN POTS.

WILL Mr. Wythes kindly tell me which he considers to be the best two Peaches for a small house to come in in succession? I want both quality and size. Likewise the best two Peaches for pot work and one Nectarine. I had thought myself of Hale's Early in pots, to be followed by Royal George and Bellegarde planted out, followed by Princess of Wales Peach and Humboldt Nectarine in pots. By having three in pots I could prolong the season considerably, as the trees could be stood outside at certain seasons. The house is 12 feet by 14 feet, but very lofty, borders inside. I want most of the fruit to come in from August to October.—YORKSHIREMAN.

\* \* \* Your selection is a very good one, Hale's Early being one of the very best. It is not one of the largest Peaches, but it is above medium size when well grown and of excellent flavour, the tree also having a good constitution. I like Early Grosse Mignonne. It must not be confounded with the old Grosse Mignonne. The true kind is rare, has globose glands, large flowers, and the fruit ripens much earlier than that of the older kind. It is a grand early Peach, good for forcing, the fruit, which ripens a few days later than that of Hale's Early, being of fine flavour. Under glass to follow it, Royal George is excellent in every way. I do not think you could have a better selection. Bellegarde planted out to succeed those named should answer your purpose, with Princess of Wales, a late, handsome Peach, also planted out. I do not advise Princess of Wales in pots; I prefer Barrington or Stirling Castle. My selection would be Hale's Early or Early Grosse Mignonne for first crop, followed by Royal George and Bellegarde, with either Lord Napier or Humboldt Nectarine, a splendid variety, good in pots or otherwise. To come in in October, Barrington would do well. Dymond would also suit your purpose. It is a good pot tree and excellent in a cool house. I have named these in addition to the others to give you a good selection, and have considered size, quality, and cropping as important details. The Nectarines are noted for their good qualities. This year Humboldt has been grand, and, like its parent, Pine-apple, it equals it in flavour and the fruit is much larger. For pot culture you may rely upon it or Lord Napier, which is earlier.

With regard to the culture of pot Peaches and Nectarines, I would advise purchasing this year good trees, specially grown for fruiting next season. The trees will be more expensive, but this outlay will be balanced by the crop of fruit, as if you purchase trees from the open ground and pot up now you will not obtain heavy crops. The trees to do well should have been grown a season in pots, and may now be potted on or merely top-dressed. If in small pots, the former will be necessary. My mode of culture with pot trees is to pot up in October or early in November. Cost may be a consideration. In such a case I would advise "Yorkshireman" to select good trees at once, pot up and stand under glass, damping overhead till the leaves fall and keeping the roots moist. Such trees not being required to fruit till August will require to be kept cool, but if placed in the open the roots should be protected from heavy rains or snow, the pots being plunged over the rims. Of course, older trees, with due attention to root-preservation, may with advantage be placed in the open in the late autumn, and any repotting is best done just as the leaves turn yellow. Many rely upon top-dressing

one year, potting the next. In repotting remove the drainage and cut away the strong roots, repotting as firmly as possible in the same sized pots and merely protecting from heavy rains till required to start into growth. Trees grown thus may be wintered in the open till March, and treated thus make a cleaner growth than if kept under glass all the year round. Plenty of water and feeding are required to finish the fruits after top-dressing with rich manure. Repotting should be done with care, well ramming the soil, using good yellow turfy loam, mortar rubble and bone-meal with clean drainage. More attention should be paid to pot trees in the way of stopping and exposing the fruit. Stopping and disbudding are more important than with planted-out trees.—G. WYTHES.

#### RIPENING OF PEARS.

SOME of the so-called second-rate varieties of Pears can be greatly improved by special treatment. What may be termed artificial ripening is not only a means of considerably lengthening the season of notoriously bad keepers, but also of surprisingly improving the quality of some of them. Then, again, early and second early varieties are often left hanging on the trees too long, the result being mealy fruit, which only keeps a short time. Williams' Bon Chrétien is the most familiar instance of this. It is the behaviour of this and somewhat similarly constituted Pears that has given rise to the old saying, that one has to sit up all night in order to catch the fruit at the right time for eating. Now if the natural time of maturation of seeds or pips was anticipated by at least a fortnight and a portion of the crop gathered and ripened artificially, successional gatherings following every fourth day or so, every fruit from a large tree might be utilised and none spoilt. The most delicious fruit of this variety that falls to my lot each year is ripened a little in advance of its natural season. Souvenir du Congrès is also becoming popular hereabouts. This resembles Williams' Bon Chrétien in most respects, only it is later in ripening. Artificial ripening of a portion of the crop in this case again has the effect of improving the quality and also of bringing out the colour on this, to my thinking, grand September Pear. Late in August a friend ripened a grand dish of this variety which took two first prizes at local shows, and the last of the crop is before me as I write. Under high cultivation the fruit attains to sensational dimensions. Following upon the heels of this variety we have Beurré d'Amanlis. Left on the tree till the dropping stage is reached, quite the finest fruit of this variety is comparatively dry and flavourless, but gather when it can be separated from the tree without undue violence, ripen a portion of the crop artificially, and then note the lusciousness of the variety. Beurré Supertin treated similarly resembles a lump of butter in appearance and consistency, and is a most delicious Pear. Even Marie Louise d'Uccle can be ripened to such perfection, as to convince good judges that it is not altogether the second-rate variety many make it out to be. Louise Bonne of Jersey is justly considered one of the handsomest Pears in cultivation, but to bring out its beauty and good quality it should be artificially ripened. Much the same remarks apply to Flemish Beauty. Most of us affect to despise Duchesse d'Angoulême, and if the truth must be told it ought more often to be classed as a stewing Pear, yet I have recently tasted fruit that had been ripened artificially which was far from being tough or gritty. It was eatable in fact and of a bright orange-yellow before being skinned. Beurré Clairgeau ripened artificially is perhaps one of the most attractive varieties in culti-

vation as far as appearance goes, and those who have a heavy crop of this naturally highly productive Pear should ripen a portion artificially. If, then, they were not satisfied with the improvement effected in this naturally coarse variety, they would yet be able to sell the fruit more readily than they would fruit of sorts much superior in point of quality, only not so showy. That great cropper, Beurré Diel, if allowed to ripen naturally is not always eatable, but some that I have already ripened artificially by way of an experiment are both taking in appearance and buttery. It does not follow that I recommend ripening this variety thus early, as in most seasons we are glad to keep it for use late in November, that is, when better varieties are becoming scarce. My idea was to see what could be done with the produce of one extra fine tree. Even the Vicar of Winkfield, good stewing Pear as it is, can be ripened so as to fit it for the dessert. Josephine de Malines, Beurré Bachelier, and a few other late Pears, including Chaumontel, will not always ripen satisfactorily under ordinary conditions, but may be brought to perfection under artificial treatment. In the case of Pitnastan artificial ripening does not wholly get rid of the unpleasant acidity observed in the case of naturally ripened fruit, but I have observed an improvement, and any way should think it desirable to ripen a portion of a heavy crop artificially. Durondeau, Marie Louise, Doyenné du Comice, Comte de Lamy, Fondante d'Automne, Passe Colmar, Maréchal de la Cour, Brown Beurré, Beurré Hardy, and a few others that could be named usually ripen to perfection under natural conditions, but that is no reason why a portion of a heavy crop should not be ripened artificially with a view to having a longer succession than can be had otherwise.

I have yet to explain what I mean by ripening Pears artificially, and to describe what appears to be the simplest and best method. It is low temperatures that prove most injurious to the quality of Pears, and subjecting them to these does not even greatly aid in keeping the fruit to any great length of time. Store, therefore, in a comparatively warm, dry room and guard against any great fluctuations of temperature, further improving the quality and hastening the ripening of a portion of the crop by placing them in boxes lined with flannel or sheets of cotton wool, and transferring to a heated forcing house or a kitchen. Placing Pears in a kitchen drawer also answers admirably. Some that I have recently ripened to perfection were wrapped separately in paper and then packed in cotton wool, a small square hamper being used for the purpose of holding them. This was set at a short, yet safe distance from a kitchen fire long enough to get all warmed through, when they were moved a little out of the way and left alone for about a week. When opened most of the fruit was ready for eating, and, as before hinted, proved to be highly satisfactory both as regards appearance and quality. W. IGGULDEN.

**Apple Bramley's Seedling.**—I notice in a recent issue "E. M." complains of the barrenness of this variety when in a young state. The experience of most gardeners who plant Bramley's Seedling is the same; indeed, there are large trees in this neighbourhood which bear very indifferently, one fine healthy specimen in my own orchard planted some fifteen or sixteen years ago having borne only one respectable crop. There are only about a dozen fruits on it this season. In the neighbourhood of Southwell, where it was raised, the soil suits Bramley's well, quite young trees yielding plenty of fine fruit. No one can find the least fault with either the size, weight,

or quality of this fine Apple, and it keeps well till May, retaining its weight as well as Mère de Ménage, which is saying a good deal. According to my experience, a more reliable Apple to plant by those who wish for a profitable and quick return is Lane's Prince Albert. Bramley's is all very well for those who can afford to wait, as in the case of the Blenheim Orange. I consider Blenheim the more constant variety of the two after it once commences to bear, although, of course, the fruit will not keep anything like so long as that of Bramley's.—J. C., Newark, Notts.

**Tomtits and fruit.**—I can fully sympathise with Mr. Sangwin (page 318) in his struggle with these mischievous pests. They do not generally make their appearance in this garden until late in the autumn, when they make a raid on any Apples or Pears which may happen not to be netted. Only to-day I discovered that holes had been made by tomtits in several of the largest fruit of Beurré Bachelier hanging on an upright cordon on a wall. Of course the fruit will go rotten very quickly even though the hole is ever so tiny. In several gardens in Norfolk surrounded by large woods tomtits are a veritable nuisance, for in spite of covering the trees with nets, the birds contrive to reach the fruit, generally selecting, as Mr. Sangwin says, the finest and best. A single herring net hung over the tree is not sufficient, as the tits are so small that they force their way through the mesh. To keep them out, the net should be hung double, and this of course keeps a great deal of light and air from the trees.—J. C.

#### FRUIT-FARMING.

AT page 329 Mr. G. Barham draws attention to the exorbitant charges of railway companies for the carriage of fruit. In the case quoted, three times the value of the article carried was charged for a journey of forty miles, and it is no uncommon remark, and one that is perfectly true, that anyone having an orchard fifty miles away will find it better policy to let the fruit lie under the trees and rot, and buy what he wants in the locality he is staying in. I could mention gentlemen in this locality who are doing this. We are continually hearing that something is going to be done for the long-suffering farmer, but if it is in the direction of fruit-farming I fear a good many things will need re-adjustment before better times will come. This has been an extraordinary year for Apples, but I doubt if many of the growers are much the richer for it. Heavy crops mean a good deal more expense in the way of labour for gathering, marketing, &c., and unless a market could be found near enough for carting, a railway journey would in nearly every case result in a positive loss; and growers who are situated at long distances from large centres of population are very much handicapped, for the profits of their labour do more to swell the dividends of railway shareholders than to fill their own pockets. Apples have been such a general crop that they are equally cheap in all parts of the kingdom, and if one cannot find a market close at home it is useless consigning them to a distant market. Other fruits have not been so evenly distributed, and in some parts Pears are scarce, but here the same difficulty meets the grower. If he can sell in his own locality all well and good, but if it means a long journey by rail the question is, what will he get by the time rail charges and market expenses are paid? Pears succeed well in this neighbourhood, nearly all kinds coming to perfection on open bush trees without the aid of walls, but it would be hazardous work to grow more than could be sold within carting distance, for our railway accommodation is a close monopoly, and no one appears to understand on what rule the charges are made. The question for anyone contemplating planting on a large scale would be, not so much the possibility of growing good crops of Pears almost every year, but whether he could dispose of them at a living profit. It seems strange that Parliament, having the power to grant to these railway companies a monopoly of the carrying traffic, appears to have no power (or else does not use it) to inter-

fers when these monopolists are strangling the home trade, as they are doing in the case of fruit. Happily there is a great improvement in orchard fruit culture, and those planted within the last twenty years are now coming to yield fine crops, but we cannot expect this improvement to go on, and orchards to spread far and wide, if there is no cheaper means of transit provided. We have been told that cheap light railways for goods traffic would do great things for Ireland, and it appears to me that something of the kind is needed in England.

Gosport.

JAMES GROOM.

#### VINE NOTES.

THE majority of gardeners are very seriously handicapped at this season and later on by the primitive means at their disposal for storing Grapes, the rooms or other places in which they have to place the bottles being utterly unsuited for keeping the berries sound and plump. Judging from what I have seen in many gardens of moderate size, a vast quantity of Grapes is spoiled annually by the unsuitable structures in which they have to be stored. During the past two winters I know of one establishment where the Grapes and bottles of water were frozen together, and when the thaw came the bottles burst wholesale, and what had been a fine lot of Grapes was completely spoiled. In this case the gardener could not help himself, as this room was the only one he could have, and there was no convenience for a stove or other means of excluding frost. In another instance the Grape room is over a stoke-hole, and the heat from the fires and boilers quickly shrivels the berries, making it a continuous worry for the poor gardener, who is expected to supply good Grapes for a long period in the winter. It might, perhaps, be advised in such cases to allow the bunches to hang on the Vines to the latest possible date, but where a large quantity of plants has to be put into the vineries on the approach of cold weather, the moisture continually arising quickly causes mould to set in, followed by considerable loss. Here is another point that comes in, viz., is it not beneficial to the Vines to have all the fruit cut as soon as the foliage has fallen? I think it is advantageous in several ways, not only in the reduced risk of the Grapes decaying if plants are in the vineries, but the Vines can be pruned at once and the houses cleaned and made ready for starting again. On a light soil liquid manure can be given the borders, furnishing the soil with plant food that can be taken up by the roots when activity commences again. We all know how carefully watering must be done in the winter with Grapes hanging on the Vines, and this system of supplying less moisture to the borders while the root action is practically at rest is opposed to all natural conditions. It is a query how many Vines are seriously crippled or injured by the Grapes hanging on the rods until late, and the consequent inadequate supply of water to the roots to maintain them in a healthy state. Again, if the Grapes are all cut and bottled at the earliest possible date, the Vines can be pruned, and if no plants are in the vineries a low temperature can be given that will afford the Vines a rest. Such a thing as the Vines bleeding is unknown according to my experience if thus pruned and treated. I believe few, if any, people now turn out their Vine rods through the front ventilators, as done in my days of probation, nor do I think there is any wisdom in thus exposing the rods to cold, wet, and frost, as I have seen Vines so treated die back and refuse to start into growth again when required to do so. It is far more rational to keep them inside, throwing open all the ventilators on every suitable occasion, thus avoiding any excitement to the Vines, and preventing them starting prematurely.

Where insect foes have been troublesome, the next few months will be a suitable period to eradicate these enemies, starting with the Vines first. All loose bark that will come away without the aid of a knife is best removed, scrub-

bing each rod immediately it is thus cleaned, thereby killing the insects exposed before they can find fresh cover. Any of the well-known insecticides will be suitable for the purpose if applied as directed by the vendors. If mildew has appeared on the bunches or foliage all the glass and woodwork should be thoroughly washed with soft soap and hot water, the walls also limewashed and the surface of the border removed and top-dressed with good fibrous loam and bone meal. Thorough cleanliness is one of the surest and best preventives of all insect or fungoid attacks, and should be insisted upon as far as possible. W. G. C.

**Keeping Plums.**—It is surprising how long Coe's Golden Drop Plum may be preserved in an eatable condition by placing the fruit on a shelf in a dry warm greenhouse or fruit room. True the skin is apt to shrivel somewhat, but the flavour remains all the same. I have also seen the Wine-sour Plum kept for a November exhibition by cutting small branches on which the fruit hung, and thrusting 6 inches of them into a Mangold Wurtzel, the moisture of which kept the Plum wood in a plump condition and the fruit from shrivelling. Grapes may also be kept for a long time by the same means.—J. C.

**Outdoor Grapes.**—The Vine which produces the Valencia Raisins of commerce is a fleshy Muscatel, very similar to the Muscat of Alexandria. It is grown in the environs of Denia and Jabea, between Alicante and Valencia. From my personal experience of these two places, I should think it is almost as likely to ripen here out-of-doors as the Date or the Banana. The loohest bunches are those of the Muscatels, but they will not do for outdoor work here. The solid clusters referred to by "A. D." are natural to the Vine, and have nothing to do with the cool conditions. In France, in Spain, in Italy, and America, where Grapes are not thinned, they are always in clusters and very small. I have ripened outdoor Grapes this year against the walls—but when shall we have such another year? I believe there is a small and delicious Grape that is produced on a Parsley-leaved Vine that would ripen here with a little trouble. I have seen it in France and Guernsey, where there was no market for it, by reason of its insignificant appearance.—J. W. SHAW, *Lingfield.*

— I enclose a small bunch of Black Hamburg Grapes to show you that Grapes can be ripened out of doors in Cheshire upon a cottage wall. Even last year I cut some bunches of ripe fruit. Good fruit could be had out of doors on cottage walls in the south of England, but not from such worn-out Vines as I have seen in Hertfordshire. The Vine from which the Grapes sent were cut was planted in 1889. It is planted on the south corner of my cottage and trained horizontally, the rods 18 inches apart. The cottage roof has about 2 feet of a projection, which throws off rain and in the spring protects the tender foliage from frost. The laterals are pinched two leaves beyond the bunch and all other lateral growth is stopped. This allows plenty of space for the foliage and ripening of the wood. I have never seen any mildew on the Black Hamburg out of doors here. Old pot Vines may be made good use of for planting on walls or trees. Vines will cover a wall more quickly than many other plants and to a greater height.—ALEXANDER TRAIL, *Fulshaw Hall, Wilmslow, Cheshire.*

— I regret that I cannot give "A. D." any information with respect to the suitability of the Valencia Raisin Grape for outdoor culture in this country, but in any case I should not advise the employment of seedling plants. I once raised young plants from seed taken from about thirty of the best French vineyard Grapes, and not one of them was equal to the parents, the greater portion having berries so small as to be worthless. Probably one of, if not the best, kinds for open-air culture in this country is the Gamin Noir. This is the Grape found to succeed best in the vineyards of Northern France, and the one of which

the Marquis of Bute's vineyard is composed. Other Continental kinds have, I believe, been successfully grown at Chiswick, and those intending to plant should try several varieties.—J. CORNHILL.

#### SHORT NOTES.—FRUIT.

**Pear Emile d'Heyst.**—This from a pyramid tree was quite ripe at the end of August. Last season it did not ripen until the third week in October. Can any reader give a reason for this?—J. C. CLARKE.

**The Mother Apple.**—Mr. Bedford, of Straffan House Gardens, sends us good examples of the Mother Apple, and writes to us, praising it as an Apple of fine flavour during the last half of September and first half of October—as good for that time as Cox's Orange Pippin.

**Pear Princess.**—It may interest "S. H. B." to know that this Pear does well as a horizontal cordon away from a wall, the fruit coming very fine and handsome. With me it bears as freely as Louise Bonne of Jersey and is superior to it in flavour, the flesh being more sprightly.—J. C. CLARKE, *Taunton.*

#### GARDEN FLORA.

##### PLATE 1039.

##### ROSE NARCISSE.

(WITH A COLOURED PLATE.\*)

A CHARMING Rose that is hardly ever seen either in gardens or Rose nurseries is the subject of our coloured plate. It is a very old variety, sent out by Avoux and Crozy in 1858, and even now it loses nothing by comparison with the best Roses of the last decade, and is altogether too good to be lost sight of or neglected. As we have often said, Rose exhibitions are of little use in helping us to find out the best garden Roses, and the complexities of Rose classification assist in burying not a few first-rate kinds in comparative obscurity. Some will place Narcisse among the Teas, others among the Noisettes, and the descriptions that are given of it give a very faint idea indeed of its many merits, owing to the exclusive standard of merit by which the majority of Roses are judged. We have even now only a few yellow Tea Roses—for Narcisse is as much a Tea as any Rose in that section—that can be trusted to flower well and freely under the varying conditions of sunshine and rain that make or mar our Rose seasons, and not only to flower, but to give great clusters of bloom where the conventional show Rose gives but one. In this variety two extremes meet, for whilst in stature it is one of the dwarfest of all the Tea Roses, it flowers so profusely, that it will not be exaggerating its merits in the slightest degree to call it a miniature Lamarque, as it is a miniature counterpart of that grand old Rose in all respects except that of the colour of its flowers, which, instead of being snow-white, are a soft canary-yellow, shading to a cream tint as they age and expand. Although dwarf, there is no suspicion of tenderness or delicacy, but it makes strong, short-jointed shoots and thick spreading bushes about 18 inches in height. Every shoot is terminated by a cluster of flowers, as shown in the plate, the number varying from three to twenty or more, according to whether the shoots are laterals or leading growths. The bursting and half-expanded buds and a full, open flower, as represented in the plate, show the form and character of the Rose, and it is second to none as regards a long-sustained season of bloom. In this present autumn,

\* DRAWN FOR THE GARDEN BY A. F. HAYWARD at Gravetye Manor, Sussex. Lithographed and printed by Guillaume Severeys.

ROSE NARCISSE.

which has brought us one of the finest autumnal displays of Tea and other Roses that we have ever seen, Narcisse has contributed its quota of blooms, and at the time of writing (October 5) is still gay with many buds and blossoms. The Rose named *Enfant de Lyon* is synonymous with Narcisse.

## THE WEEK'S WORK.

### KITCHEN GARDEN.

**THE ROOT CROP.**—There will be a good deal of work now amongst roots, as lifting will have become general, and, although Carrots and Parsnips are fairly hardy, they are not improved by being frozen and refrozen, to say nothing of the labour and inconvenience of getting to the roots when the ground is hard. Sometimes severe weather sets in quite unexpectedly and at an early date, taking the gardener off his guard. Temporary covering is then necessary, as the roots cannot be lifted in a frozen state. Beetroot does not stand more than 7° or 8° of frost, and this week, owing to sudden and severe frost, I have mown the Asparagus beds and covered the Beet with the growths. This forms a capital protection, and the Beet will take no harm till the frost goes. As the intermediate forms of Carrots will be used first, the Long Red Surrey and Altringham should receive a little more attention in storing, more soil being laid between each layer of roots than in the case of the shorter varieties. Where a good many Parsnips are grown, and it is certain that the supply will hold out till spring, a portion may be left in the ground, a little soil being drawn up to the roots with the hoe. For general winter use I prefer to lift and lay them in up to the crown in a sheltered nook or corner, and then to cover with a good thickness of Bracken. Lay them in as closely together as possible in the rows, treading the soil between each lot firmly. When treated thus they retain their flavour and firmness, and can be got at easily, even in the hardest weather. Salsafy and Scorzonera may be treated exactly in the same way, but in the event of very hard frosts, more covering will be needed than for Parsnips. Jerusalem Artichokes retain their flavour better if left in the ground, and although it will be necessary to lift a portion of the crop and store in root room for present use, the remainder of the bed may be covered with Bracken or litter, that the roots may be easily dug later on.

**ONIONS.**—Take advantage of wet or snowy days to overhaul the stock of Onions and remove all decayed bulbs. Any just showing signs of going should be laid by themselves and be used soon, as there is seldom time for stringing when the crop is harvested in September. A percentage of the best bulbs should be done, and suspended from the roof on wet days when outdoor labour cannot be proceeded with. The remainder can then be spread out thinly, so as to get the benefit of more air. Although Onions prefer a dry atmosphere, thorough coolness is essential; lacking this, the bulbs soon lose weight and often decay, especially if not very well matured. Those lying on floors are the better for being turned over once in three weeks. The first time the ground becomes fairly dry go over the autumn-sown beds and firm them well, as if much frost catches them when in a loose condition, it injures the young bulbs, especially on heavy soils. Before firming these run the Dutch hoe between the rows and remove all weeds, drawing a narrow reke through them after firming is completed. Apply soot and wood-ashes in equal quantities, as, although the grub does not usually attack the bulbs at this season, by incorporating this mixture with the surface soil there is less liability to attack during March and April. Moreover, on warm sandy soil soot is beneficial amongst Onions applied at any time. While speaking of firming Onion beds I may mention that it is also needed on breadths of autumn-planted Cabbages, as many of them are sure to be loose. After making firm draw a little soil to the stems to steady them till the spring.

**TURNIPS.**—It will be wise to lift all Turnips which have grown to their normal size except Chirk Castle, which is so hardy that it will endure almost any amount of wet and frost without decaying. Turnips keep best if clamped similarly to Potatoes, but covered down a little less heavily, as heating in mild weather causes top-growth and general deterioration.

**FRENCH BEANS.**—Choice summer vegetables having now disappeared, it behoves all those who have the convenience to get in a good batch of dwarf forcing Beans. When speaking of the first batch a few weeks ago I mentioned an 8-inch pot as being suitable, but that size should no longer be used, a 6-inch being of ample size. Sow Osborn's Forcing, Sutton's Dwarf Forcing, and Sion House for the next three months, and allow five, or at the most six, plants to remain in the pot after thinning has been performed. Where there are any strong wide shelves in light houses and tolerably close to the glass, the best plan is to grow the Beans in shallow boxes similar to those used for striking Geranium cuttings. Drain them well and mix a little rotten manure or quick-acting fertiliser with the loam, as the rooting medium being so limited there need be no fear of sourness, and the roots are able to assimilate the whole of the nourishment. As before stated, a limited root space and a light house which can be kept at from 60° to 65° at night are the chief essentials for successful Bean culture in the dark months of winter. I usually support the early batches with portions of half-worn Birch beams, topping them with a sharp knife to give them a neat appearance. If not standing near hot-water pipes the soil will only need one gentle watering until the Beans are through the soil. Repeated doses before germination takes place are sure to end in decay. Where a fair amount of atmospheric moisture can be maintained, Beans are best without being syringed overhead at this time of year.

**PROTECTING PARSLEY.**—If a supply of this has not been got into pits or frames no time should be lost. Several months ago I advised pricking off plants from a summer sowing into a spare pit, so as to get established plants, as such are not so prone to damping as are those lifted at the present time, thus receiving a check. Expose fully in fair weather, and hand-pick and surface-stir occasionally. If any bed of a choice strain is wanted for seed next summer it should also receive a temporary protection, as severe frost cripples, if it does not kill it. Erect a rough framework over it, and roll mats or canvas along each evening in bad weather. The same kind of screen will be needed for young Lettuces left in seed beds, as the warm weather in September caused a soft, sappy growth, which will stand but little frost. Let plenty of Bracken be got into the frame yard in case of sudden need. This is most useful for putting over frames containing Endive, Cabbage, and Cauliflower.

**BROCCOLI.**—As a rule, Broccoli for mid-winter use is much less grown now than formerly, and no wonder, as it is a very precarious crop, and if it fail through frost, gardeners with only a limited sized kitchen garden are placed in an awkward position. In such gardens the ground had better be planted with Rosette Colewort, and then there is always something to cut at, no matter how severe the weather may be. In most places, however, both Autumn Giant Cauliflower and Self-protecting Autumn Broccoli are regarded as indispensable, as by watching them and lifting in time, the latter will afford a supply till Christmas. The forwardest rows of this Broccoli, with heads the size of tea-cups, must now be lifted with as much soil attached to the roots as possible, and laid in, in leaf-mould or soil, in cool frames, pits, or open sheds, where the necessary slight covering of Bracken or litter can be given in case of prolonged frost. I have seen Broccoli kept for a long time in cold, shallow brick pits, and covered with straw hurdles made on the premises in wet weather. These straw hurdles are capital things for using over beds of Lettuce, Cauliflower, Cabbage, and early Endive growing in the open

borders, boards being placed on edge along the ends and sides for the hurdles to rest upon.

**HEELING IN BROCCOLI.**—This is commonly practiced with such sorts as Snow's and other winter varieties, and consists in first taking out an opening at the north end of the brake and then forcing the spade under each plant and levering it over, banking the soil from the next trench over the stems. Even then it is advisable in low-lying gardens to leave a pathway here and there, so that litter can be carried down and laid over the foliage in times of unusual severity. I have found Veitch's Model stand most winters without any protection. The same may be said of Cooling's Matchless Spring and Methven's June, a late Broccoli of great merit. J. CRAWFORD.

### FRUIT HOUSES.

**EARLY PEACH HOUSES.**—With such a favourable autumn for ripening the wood there is a prospect of good crops next year, and as far as my observation extends there should be less bud-dropping than usual if the roots have not suffered from want of moisture and the trees have been supplied with abundance of air. The leaves in early houses have now mostly fallen, and the longer the trees can be exposed the better, a touch of frost being beneficial. In many places fruit houses have to be utilised for Chrysanthemums whilst in bloom, but these plants should not be allowed to interfere unduly with the trees, as if much excited at the resting season bud-dropping later on will be troublesome. When plants are stood in these houses it often happens the borders get much moisture from watering just in one place, while near the stems the roots are quite dry. This should be avoided, also treading or puddling the border in any way. Trees on which the leaves hang long may be lightened by shaking or drawing the hand up the shoots. I do not advise brushing off with a broom, as the buds when prominent are soon injured. Strong shoots at all green or late-planted trees may require a little fire heat with plenty of air to ripen the wood, and in such cases it is best to expose as much as possible. Trees fully matured may now be partially untied from the trellis, thus getting more light and air and be made ready for pruning.

**CLEANSING AND PRUNING** will be the necessary work in early forced houses, as many require to start them at the end of November or early in December. There is no better time to do necessary repairs, painting, and limewashing, the last important, as it adds to the appearance and at the same time destroys all insects that may be in the crevices. Cleansing of the paint and trellis or ironwork is equally necessary, well brushing the same with soft soap and warm water to remove brown scale or other pests. Some kinds are not so robust growers as others and need a different style of pruning. If these latter have much small wood and are at all subject to bud-dropping, the knife must be used sparingly and a greater quantity of small twiggy wood left, as it often happens this small wood will furnish a crop when the stronger fails. Such Peaches as Alexander, Waterloo, and Hale's Early are more subject to bud-dropping than others. The same remarks apply to Nectarines Lord Napier and Elruge, these often bearing best on the small greenish looking spray, the stronger well-ripened shoots casting their flowers. If previous calendar notes have been followed in the way of cutting out the old fruiting wood and crowded shoots as soon as the trees were cleared of their fruits, pruning will not take long. The chief work will be thinning out. By summer pinching there should be an absence of gross shoots, but at times they may be overlooked. These must not be allowed to remain unless it is necessary to make good any gaps caused by canker or disease. In pruning it should be the aim of the cultivator to keep the trees as evenly balanced as possible, and if there is an inclination to grossness, this must be remedied by removing the coarse shoots, allowing the smaller wood more freedom. In cutting back strong

growth, make a clean cut as close to the parent branch as possible. It is always difficult to advise as to length of bearing wood left, so much depending upon the age of the tree. I am an advocate for extension, but, of course, when certain limits are reached there must be more knife work if pinching has been neglected. In the majority of cases the fruiting growths may be left 18 inches to 2½ feet long and as near the main shoots as possible, removing any wood on which there are no buds to make room for new wood, shortening the shoots to a triple bud whenever possible. Smaller shoots will not require shortening, but should be treated as fruiting spurs. Weak, spindly growth, left specially to provide fruit in case of the stronger wood failing, may be cut back if too long. In many cases it will not be necessary, as any not required to fruit may be removed when disbudding. Unless the trees are small, it is not advisable to remove all ties from the trees, as the main branches will need support to prevent the trees being broken. In cleansing it is well to tie a number of shoots together so as to avoid rubbing off the buds, which are very prominent this season.

**DESTROYING INSECT PESTS.**—The Peach and Nectarine, in common with most forced fruits, soon get infested with insects if not well managed. In all cases it is advisable to thoroughly cleanse at this season to prevent the enemy gaining a foothold. Mealy bug is doubtless the worst pest. Many advise paraffin in a raw state mixed with tepid water, but this in inexperienced hands becomes dangerous. Soluble paraffin is a safe mixture and, unlike the raw oil, does not float on the surface; it is excellent for syringing to clear the trees from bug, and there is no better wash than this mixed in tepid rain water, well brushing it into the crevices. If ordinary paraffin is used, it should be first mixed with soft soap to make it soluble. For brown scale, Gishurst compound, an old remedy, but a good one, may be used. For red spider the same remarks apply. I have found it advantageous to paint the old branches and bark of badly infested trees. This often reaches any portion missed with the syringe and does the trees good. The wood of this year need not be covered and the paint may consist of Gishurst, clay and a little sulphur, with sufficient water to make it the thickness of ordinary paint.

**LATER PEACH HOUSES.**—It is not too late to remove any trees to make good those not in condition, or to substitute another kind. Such trees need to be home-grown so as to be lifted at once and get a good ball of earth and roots. Trees from open nursery quarters will not bear forcing, whereas the above will if lifted carefully. Young trees from a distance may be used to fill up the wall spaces in the open. The late trees should now be exposed as freely as possible and care taken that the roots are in a moist condition; any borders found dry when replanting should get copious supplies of water. The leaves as they change colour should be removed. By clearing up frequently much insect life is destroyed.

**WINTERING POT STRAWBERRIES.**—I like these to be left in the open as long as possible if the weather is not too wet or severe, as the frost in a measure prepares the plants for forcing. Excessive rainfall is injurious, and must be guarded against. The chief drawback in delaying housing or protecting the plants is that sudden frosts soon injure the tender roots, and often one cannot conveniently house just at the right moment. By placing the plants in houses they often suffer and get infested with green fly; if placed in Peach cases or in cool fruit houses a thorough watering overhead will be of great benefit, also giving as much light as possible. Strawberries will not stand coddling. A thorough rest is essential, and, so far as my experience goes, there is no better means of protection than cold frames, plunging the pots in ashes, leaves or fibre. The ashes can be thrown off in fine weather and the plants freely exposed. The older plan of stacking is now not much practised. I used to winter the plants in this way, having a great number, but do not ad-

vide it, as the plants get too much dried in severe weather, and when required at certain times to force cannot be moved, being frozen in a mass. A good plan is to plunge well over the rims of the pots if they cannot be given frame protection, and on a well-drained or sloping border this is preferable to stacking. I treat the latest lots in this way and house the earlier and midseason varieties in frames, plunging in ashes and exposing freely till wanted.

**LATER PLANTS FOR FORCING** will need more care than those full of roots and their growth finished. These should be given the best place, but free of warmth. In some gardens, owing to the drought, it was difficult to get early runners, so that there may be a larger percentage of late-potted plants this season. These will well repay cool house or frame protection, and should be kept moist at the roots, as premature ripening off will cause weak bloom. Any small plants left for spring planting to provide stock should likewise get timely protection. These will do well plunged in a warm border, and will then start early into growth. Plants grown in beds intended to lift and pot up may with advantage be well trodden round in light soil, and all bad leaves cleared away from the crowns to ripen them. G. WYTHES.

#### NOTES FROM GUNTON.

GUNTON is at all times well worth a visit, but never more so than during August and September, when the fine old trees are taking on the autumn garb, and fruits, vegetables, and hardy flowers grace the well-kept gardens and pleasure grounds. Everything is well done at Gunton, no special hobbies being indulged in. The Pear trees on walls, from which fruit has so often won first prizes at London exhibitions, are this season carrying grand crops of heavy, well-shaped fruit, Doyenné du Comice, Marie Louise d'Uccle, Glou Morceau, Marie Louise, and many other standard sorts being especially fine. Mr. Allan has had Doyenné du Comice from 18 oz. to 20 oz. in weight from south and west walls. Apple trees in espalier and bush form are carrying fine crops of fruit, Lord Suffield, Potts' Seedling (a favourite Apple at Gunton), Cox's Pomona, Fearn's Pippin, King of Pippins, and Ribston being conspicuous for size and beauty. As might be expected, young Strawberry plantations look remarkably healthy, Mr. Allan still adhering to his old plan of sowing his Onions 2½ feet apart and planting the young Strawberries between the rows at the beginning of August, thus having fine Onions and fine Strawberries, Gunton Park, Lord Suffield, and that delicious variety Empress of India growing quite as vigorously as well-known older sorts. Figs on open walls were badly crippled last winter, but trees on walls under glass and bush trees occupying low pit-like houses have this year yielded most abundantly; in fact, I never saw finer Negro Largo. The Gunton soil grows magnificent vegetables, and Mr. Allan is very enthusiastic in their culture, having a good many special strains of his own. His selected stock of Spanish Onion is, I think, the finest I have ever seen, its depth, weight, and general symmetry being exceptionally good. The Gunton vineries have for years produced splendid Grapes, some of which have taken foremost positions at leading exhibitions, and this year is no exception to the rule. I saw some grand bunches of Duke of Buccleuch on a Vine grafted on Black Hamburg, and noble bunches of a new seedling black Grape of splendid appearance and very rich flavour, and which would probably have received a certificate from the Royal Horticultural Society, who thought highly of it as a late Grape, had not the raiser candidly confessed that it was a shy bearer. At the time of my visit the flower garden was looking well. As at Blickling and various other places in East Anglia, the formal style of bedding has been abandoned, fewer Geraniums and similar plants and more hardy subjects being used. This saves a deal of labour in propagating and

housing, and at the same time gives a capital effect. Everybody has heard of the Gunton Violets, and this year the plants look as well as ever. The garden being large, the site for growing them during the summer is changed every year. Gentle warm beds are still employed for the principal lots after lifting them. J. C.

#### ORCHIDS.

##### DECIDUOUS CALANTHES.

THE flowering season of these extremely useful Orchids is once more close upon us, and in proportion to the care bestowed on their culture, the flowering return will now be satisfactory or the reverse. When we consider the many places in which these plants are met with in really good condition, often where scarcely any other Orchids are grown and where seemingly no special attention is given them, it would be absurd to say they were difficult to manage, and yet it is a fact that in many places where other and more essentially difficult plants are well done, Calanthes are not seen in anything approaching good condition. There are several things that tend to this unsatisfactory state, and I think I am right in saying that the most frequent cause of failure lies in the fact of their being kept too cool either while in flower or after the blossoms are past and the plants at rest. So much house decoration has now to be done in many places, that the stock of winter-flowering plants is seldom large enough to meet the demand, and if necessary the Orchid house has to be laid under contribution. The plants then are placed in living rooms that have the windows thrown open in early morning and are often injured by the low temperature thus caused. The amount of this injury is not even suspected at the time, for even if the flowers are damaged, the dry looking pseudo-bulbs of the Calanthes are apparently none the worse, and when in spring weak and miserable-looking growths are produced, the cultivator wonders what is wrong with the plants and alters his temperature, mode of watering, or some other detail, possibly to their still further disadvantage. Want of room in the warm houses, too, may sometimes account for the same backward tendency of the plants. It is better in all cases to leave the pseudo-bulbs in the pots in which they have been grown for the winter, but if room cannot be found for these in a house that does not fall below 55°, it is far preferable to turn them out and lay them thickly in boxes than to remove them to a cooler structure.

Many growers have their own favourite plan of starting the pseudo-bulbs. Some lay them on boxes or pans of Sphagnum Moss, to remain there until the young shoots begin to root; others prefer to pot them into small pots in similar material, repotting into larger sizes when these are filled with roots. I have tried these methods, but could never see any advantage from them, and now always pot them at once into their flowering-pots and rely upon careful watering in the early stages of growth to bring them safely through this period. The repotting may take place at any time after the flowers are past, but, preferably, before the plants begin to grow. If done earlier the compost must of course be kept perfectly dry for a considerable time, and this is why I prefer doing it later. In order to grow Calanthes strongly a much more substantial compost than most other Orchids require is necessary, and the bulk of this should consist of nice mellow, fibrous loam. Either a fourth of well-dried cow manure or a little of some approved artificial fertiliser should be added, while to prevent closeness, add plenty

of finely-broken crocks, charcoal and a little chopped Sphagnum. Good drainage is necessary, and over the crocks a very light sprinkling of half-inch bones will be of assistance late in the season when the roots have exhausted the food supplies in the compost. A little of the old root may be left on the bulbs, as this helps to secure them in position without burying them deeply. They should have the base about half an inch below the surface, and the number of bulbs placed in each pot will depend upon their size and the purpose for which they are required. If simply for cutting from, rather large pots are to be preferred, but for decoration they may vary, some of the smaller bulbs of *C. Veitchi*, for instance, being very useful if placed singly in 4-inch pots, it being easy to hide these with small pots of Ferns, *Panicum*, or other fine-foliaged plants. No water must be given until the young growths are well above the soil, and even then it is only necessary to damp them over lightly, always using tepid, soft water. As the roots commence to push out into the soil they may have a good soaking, and then be allowed to get quite dry. These waterings will be more frequently needed as the roots reach the sides of the pots. When the latter are filled, an abundant supply will be needed, and occasional doses of weak liquid manure are helpful when the new pseudo-bulbs are swelling. Soon after these attain their full size the flower-spikes will be showing at or near the bases of the bulbs, and when the sheaths surrounding these break, care must be taken in watering that they are wetted as little as possible. By the time the first flowers show colour, all the foliage will generally have fallen from such as *C. Veitchi* and most of the varieties of *C. vestita*, when the supply of water must be diminished, but not entirely withheld until the blossoms are over. The heat of the East India house is most suitable for them, and all through their growing season they must have as much sun as possible without scorching the foliage. They must have constant attention all through the summer, and will need frequent rearrangement as they grow, so that each plant stands clear of its neighbour, otherwise the foliage will be soft and flabby, and not of the kind that will give healthy pseudo-bulbs and vigorous flower-spikes. Scale often attacks the foliage of *Calanthes*, and if the atmosphere is at all dry, red spider may also be troublesome, but both these pests may be kept under by ordinary vigilance, the remedy being the same in each case, viz., timely and judicious sponging and careful balancing of the atmospheric conditions. Large pseudo-bulbs frequently produce two, or even three new growths, and by means of these the species are increased, but if a quicker mode of propagation is desired, each one may be cut vertically into three or four and placed at once in small pots of light compost in a propagating pit, when each portion will push a young shoot. Considerable care is necessary if this method is practised, and beginners in their culture should attain a certain degree of proficiency before commencing these rather unnatural operations.

H. R.

**Oncidium hæmatochilum.**—This very distinct and brightly coloured *Oncidium* is, unfortunately, very seldom seen. It is a moderately strong grower, with large spotted leaves, and does not produce any pseudo-bulbs. The flowers occur on stiff, erect racemes, and each bears a dozen or more, each upwards of 1½ inches across. The sepals and petals are brownish yellow, with spots varying in colour from rich crimson to chocolate, and the lip is light crimson, spotted on the edge with dark brownish purple.

This species thrives well in suspended baskets in a compost consisting largely of Sphagnum Moss, a very little peat and a few lumps of charcoal being added thereto. During its growing season a moist atmosphere and fairly high temperature may be given it, and plenty of water is needed at the roots. After the flowers are past very little water will suffice, and the temperature may also rule considerably lower, but should never go below 50°. It is a native of Guatemala, whence it was introduced in 1835.

**Lælia pumila.**—When seen in good condition this is a charming species, but it is not everywhere well grown. It is a small growing plant with pseudo-bulbs about 3 inches in length, each of these bearing one leaf. The leaves are large considering the habit of the plant, being in good forms upwards of 4 inches across; the sepals and petals are light rosy purple, the lip deeper in colour, especially on the front, and in some varieties edged with white. *Lælia pumila* is best grown in baskets suspended from the roof at the cool end of the Cattleya house. A very thin layer of peat and Sphagnum will be sufficient for it, and the drainage must have special attention. It is of the utmost importance in growing *L. pumila* and the several nearly allied kinds that a nicely tempered atmosphere be always maintained. The supply of fresh air must be unstinted, yet the ventilators must be so managed that no cold draughts play upon the plants. Thus they are safe from sudden checks, and even if the plants do not make very large growths or increase much in size, it is something to have them healthy and flower regularly. The flowering season is just past, and the present is a good time to give a light top-dressing if necessary. *L. pumila* was introduced from Brazil in 1838.

**Dendrobium album.**—A well-flowered plant of this distinct old species is not often met with, and it is difficult to say why it is not more grown. It has very much the habit of *D. chrysanthum*, and, like that species, flowers upon the current year's growth occasionally while the leaves are still green. The individual flowers are clouded white with a yellow disc to the lip. *D. album* requires the heat of the East India house all the year round, and may be grown on large cork blocks dressed with Sphagnum Moss, the long pendulous stems showing to great advantage in this way. The plants may also be grown in moderately large wood baskets, these being suspended from the roof. It spoils the effect of the plants to be staked or tied in any way, especially as is too often the case with pendulous kinds. It is a native of India, and was introduced in 1842.

#### CATASETUM BUNGEROTHI.

Few Orchids have attracted more attention than this remarkable and wonderful species, with its widely-differing male and female flowers. Although at one time it was very expensive, it can now be purchased at a comparatively cheap rate, and all who like curious flowers and take an interest in them should grow a few plants. Although the female flowers are seldom produced, the usual or typical ones are sufficiently interesting to merit attention. These are pale green when opening, afterwards becoming of the purest white. The spikes are produced from near the base of the fusiform, scaly pseudo-bulbs, and bear few or many flowers according to the strength of the plant. *C. Bungeirothi* requires plenty of heat while making its growth, and as the roots are easily damaged by closeness of material, a little care in the preparation of the compost is well repaid. The former are rather large and of a fleshy nature, and consequently anything used about them should be rough and open. Three parts of clean, freshly-picked Sphagnum—the other part being made up of peat fibre and broken crocks—will make a suitable mixture. They may be grown either in pots or baskets. Personally, I prefer pots. The drainage must be kept free and open by protecting it with a layer of Moss. Small plants are difficult to start, but when once they

obtain sufficient strength to push the roots freely but little trouble will be found with them. At the time the new shoots are starting from the base a good deal of care is necessary in watering, and even when growing freely no water must be allowed to drip into the centre of the growths, or it will assuredly mean their destruction. When the roots are well advanced plenty of water must be given, and the plants must not be shaded more than is necessary to prevent injury to the foliage. As soon as the pseudo-bulbs are complete the supply of water must be diminished by degrees until all the leaves have fallen, when only enough must be given to prevent the pseudo-bulbs shrivelling. The foliage is apt to be attacked by scale, and occasionally red spider, which must be kept under by the usual means. *C. Bungeirothi* is a native of Ecuador, whence it was sent to Ghent by its discoverer, whose name it bears, about 1885.

R.

**Miltonia spectabilis.**—Introduced into this country many years ago, this *Miltonia* is still one of the most useful Orchids in cultivation. In the form of a large specimen bearing a dozen or two flower-spikes it is very showy, that is if a good variety of it is obtained, for the inferior ones are not worth house room now that there is such choice of good things among Orchids. The finest specimens of this *Miltonia* I ever saw were in large baskets, with nothing but Sphagnum and charcoal for the roots to work into. They were very showy when in flower, carrying a score or more good spikes of bloom. If pots are used they should be nearly filled with drainage, but I should certainly advise the employment of baskets and very little if any peat. A little shade is needful, but plenty of light, with a tolerably free admission of air in fine weather, is of great importance.—J. C. B.

#### THE GARDENS AT BURGHLEY, STAMFORD.

THE High Park Gardens at Burghley are at all times interesting, but now they are particularly so, and the walk from the quaint old stone-built town of Stamford, past the magnificent mansion and through the park with its stately avenues is itself an experience worth going miles to enjoy. These avenues are threefold in plan, like the nave and side aisles of a cathedral. "Burghley House by Stamford town" was built by Elizabeth's great Chancellor or Treasurer in 1575, his principal residence then being at Theobalds, in Hertfordshire. Even Cromwell was struck by the magnificence of Burghley, and spared the place; and Queen Elizabeth, who came here twelve times, is reported to have said that "Burghley was fit for a king"—a far nobler sentiment than that of William III., who thought it too magnificent for a subject to possess and enjoy. The grounds here were much improved by Capability Brown, the gently swelling mound near the house and the river-like winding of the lake being very suggestive of his method. Turn where you will at Burghley you feel within precincts that are regal, but it is with the great kitchen gardens at High Park that we are most interested to-day. Mr. Richard Gilbert has long held the management here, and some of his best cultural results are well known to readers of THE GARDEN. It is worth one's while to go to Burghley in order to see how luxuriantly all fruit trees and vegetables thrive, this being specially true of Strawberries, Cucumbers, and Tomatoes of the very best kinds. The splendid Strawberry runners now being turned out of small pots and sent all over Europe are wonderful in health and strength, the balls a mass of white rootlets. Cucumbers are largely grown for seed, and the vineries and Peach houses are in the best order and the fruit splendid in size and colour. It must not be imagined that stimulants of the best are not used, for Mr. Gilbert is a cultivator of the good old school, and he full well knows that "out of nothing, nothing comes." Flavour is looked upon as of the utmost importance, even though size and

density of cluster in the case of Grapes are also a result looked for and obtained. Mr. Gilbert's Grapes are worth seeing even in these Grape-growing times. The bunches are solid and do not fall all over the dish when they are placed on the table. The berries are as plump and as blue as Sloes. Peaches indoors are of course over, but I saw fine ripe fruit here and there on the walls. Morello Cherries I never saw so large, so black, and so perfectly ripened before.

Apples are a speciality here, and Mr. Gilbert thinks highly of Laxton's Schoolmaster, which, as he puts it, "will keep Laxton's name green for half a century to come." The Stamford Apple, now known as Peasgood's Nonsuch, is also well grown here, together with all the standard varieties, Lord Suffield, Warner's King, Burghley Seedling, November Belle, and Grenadier. Barnack Beauty is another fine Apple of local excellence. Frogmore Prolific and Golden Noble are very fertile, and Laue's Prince Albert is to be fairly tried, though it does not appear to do so well in the midland clay as near London on light gravelly soils. A tree of the pretty little French cook's Apple, now known as Knight's Late or Lord Exeter, is bearing a heavy crop, and is especially interesting as having been brought here from the Continent many years ago. There is an Apple orchard here of about 7 acres, containing 400 trees of kinds best suited to the soil and climate. The kitchen garden at Burghley is about 14 acres in extent, protected by surrounding and cross walls, thus affording shelter and warmth for both wall trees and the other garden crops.

One of the features of Burghley must not be forgotten, viz., a fine healthy Walnut tree in the little enclosure near the gardener's lodge, which just now is literally laden with fruit. This tree was planted by the late Marquis of Exeter about forty years ago, and is now very highly prized as a memorial of his great interest in horticultural pursuits. Here also may be seen one of the oldest and best of all the golden Roses, and one long prized in old-fashioned gardens. All the old authors mention it, and the worthy Dean of Rochester alludes to its superb beauty, while regretting that it would not thrive with him. It is the old *Rosa sulphurea* (= *R. hemispherica*), or golden Cabbage Rose, one tradition of which is that it was brought from the East by the Knights Templar when returning from the holy wars in mediæval times. Come from whence it may, it is figured in the *Botanical Register*, t. 46, but that coloured illustration gives but a faint idea of its superb beauty as seen in perfection in the Burghley gardens. F. W. BURBIDGE.

## STOVE AND GREENHOUSE.

### TUBEROSES.

REGARDED from an all-round point of view, the Tuberose is valuable alike to the private gardener and the market grower. The exceeding purity of the flowers and their pleasing fragrance are among the most valued points, though by no means least in point of general usefulness is the way that every flower as it expands may be used. This to the florist is, of course, of extreme importance, and equally so to the private gardener who daily has to furnish buttonhole flowers, and also daily provide fresh supplies of pleasing or fragrant blooms for the dinner-table or other purpose. In either of these instances a long succession of such flowers is of greater importance than a large display at any given season. The former is also the more trying to the gardener who has to produce daily supplies of such things. But whoever he may be, he will find very few plants of greater service than the double Tuberose known as the Pearl. Happily, the Tuberoles lend themselves readily to varying cultural methods, such

as are calculated to prolong their season of bloom considerably; so much so, indeed, that they may be had in flower for the greater part of the year. It is a comparatively easy matter for those who have some knowledge of the subject to select tubers that will soon start into growth, or, more correctly, will soon produce their spikes of flowers. Judging by the percentage of these, it is by no means improbable that it is an earlier flowering variety naturally, and that a selection of them in their American home may prove of some commercial worth. But, taking the ordinary run of tubers, the simplest way to obtain the earliest flowers is to pot them into 3-inch pots as soon as received, and plunge on a bottom heat

also be prudent that the soil be of much the same temperature as the house, and that the plants shall have been removed from the bottom heat bed a few days prior to the work being done. This batch will generally carry a supply of flowers to midsummer. From this date and throughout July and August prices range so low for Tuberoles, that many florists endeavour to be without them during these months, or at least to provide a limited supply only. Throughout the autumn and onward to Christmas Tuberoles are much esteemed. When required for late work they must be kept in a frost-proof shed or cellar till the end of May or middle of June. Then pot them into small pots in fairly good sandy loam with manure added and place in the

*Tuberoles.* From a photograph sent by Mrs. H. Knight, Grange Road, Lewes.

of about 75°. Give one thorough watering at the start and then spray occasionally with the syringe, using tepid water. Where darkened frames are obtainable, cover the tubers with them. In other cases a few may be potted and plunged in boxes of fibre and placed over the hot-water pipes, taking care at all times to attend to watering. Three-inch pots are always best for earliest work and frequently conduce to the spikes pushing early. Some will be sure to push spikes without producing foliage, and all such may be pushed forward on the bottom heat till the earliest flowers begin to open.

A second early batch may be made of those that produce foliage in the ordinary way, giving all such a shift into 5-inch pots when the smaller ones are fairly filled with roots. It will

open, covering them completely with coal ashes or fibre. One thorough watering should be given before covering them up, and afterwards only occasionally till growth is apparent. In many places these late ones are the most important batch. As the plants are ready they should be shifted into 5-inch pots and grown on in frames, or at first only shelters. The use of a richer soil is advised with these so as to promote a good leaf growth before being housed. Frequent watering overhead and occasionally with clear soot water will prove helpful. With the advent of cooler nights in October or even earlier, the sashes must be put on, and early in the afternoon at closing time moisten the plants overhead. All late Tuberoles when housed very quickly become infested with red spider or thrips.

To keep all such in check as much as possible I have found it a capital plan while the plants are still in frames outside to water overhead twice weekly with liquid manure. Do this late in the afternoon and close the frames at once. The foliage will feed on the manurial fumes present, and all the usual pests will be few and far between. From these frames or pits the plants may be housed as required and as the flowers approach the opening stage. Care should be taken not to house these late ones much before the stage suggested, remembering that throughout the treatment has been one of retarding, and the plants quickly respond to heat when placed in it. The exceptional heat of the past September has surpassed all previous experience, the plants coming forward by leaps and bounds. Should red spider put in an appearance, a solution of soft soap and quassia will prove helpful. Take two tablespoonfuls of the former and a 5-inch pot of the quassia chips and boil for twenty minutes, using rain water. When cooled down this will make sufficient for three gallons. This may be used freely till the

flower-spikes are fully grown when it must be discontinued. E. J.

**Ivy-leaved Geraniums.**—These beautiful plants have lately been conspicuous in the flower garden by reason of their blooming more freely late in the season than during midsummer, when the ordinary zonals are aglow with colour. There are now so many beautiful Ivy-leaved varieties, that it is well-nigh impossible to particularise the best, but I do not think any of the newest ones can surpass the old well-tried Mme. Crousse and Souvenir de C. Turner, the flowers of the former being of such a soft pleasing colour, that they harmonise well with a great variety of combinations when used in mixed beds, while the latter has such a sturdy bold flower, that it is one of the best for outdoor decoration. For hanging baskets few plants can equal these two varieties. If cut flowers are in request, I do not think anything is so useful to the gardener as the back wall of a greenhouse covered with a mixture of Ivy-leaved Geraniums, for having good long flower-stalks and forming such large trusses of bloom they are just the thing for bouquets or filling vases. I find they flower more freely when planted in boxes or pots with only a limited root-run than when grown in deep rich borders. It is surprising what a large specimen may be grown and kept healthy for years in a pot under a foot in diameter if a little artificial manure is given with the water during summer.—J. G., *Gosport*.

**Shrubby Veronicas.**—These are just now very bright and cheerful, not only in the favoured spots along our southern and western coasts, where they are hardy and form large bushes, but even where they have to be treated rather as greenhouse plants. As such they are very useful, and during the autumn and early winter, when little else but Chrysanthemums is to be met with, a few neat bushes of Veronicas afford a pleasing variety. The fact that they will keep in health and continue to bloom in a structure that is just kept free of frost is another great point in their favour, for neither the blossoms nor leaves are liable to damp during the dull days of winter. In speaking of these Veronicas as hardy, exception must be made in the case of winters such as the last, for they perished in places where they had stood for years. Some of the varieties are very popular with those growers who supply the London costermongers with plants, for at some periods of the year immense numbers are disposed of in the streets of London in the autumn.—H. P.

**Chrysanthemum frutescens Aurora.**—This is very useful where a continuous supply of flowers has to be maintained. It is of a dwarf, freely branched habit of growth, so that profusely-flowered specimens may be had when very little more than a foot high. The flowers are double and of a clear bright yellow colour. It will continue to bloom for months together; in fact, so free-blooming is it, that when young plants are required to grow on as quickly as possible, the flower-buds must be continually pinched off. Grandly grown little specimens of this Chrysanthemum may be met with in Covent Garden Market at the present time, and they seem to meet with a ready sale.—H. P.

**Abutilon Sanglant.**—This is one of the best of the bright red-coloured varieties of Abutilon, and in making a selection it should be included. It is of good free growth, but with occasional stopping will form a neat bushy plant in a small state more readily than some of the others. *Boule de Neige* still continues to be the best white variety, and of the numerous yellows I like *Golden Fleece*. The double-flowered form of *A. Thompsoni*, which attracted a good deal of attention a few years ago, does not as a rule bloom so freely as the others, hence it is not very popular. One striking feature connected with Abutilons is the fact that there are so many varieties with variegated leaves, several of which are used for bedding out during the summer. One of the newest of these variegated Abutilons is *Souvenir de Bonn*, which received an award of merit from the Royal

Horticultural Society about a couple of years ago. It is a free growing variety with deeply lobed leaves, which are broadly, but irregularly edged with creamy white. The flowers of this are yellow, deeply veined with red. Another variety, *navium marmoratum*, has the leaves marbled with pale green and yellow, while much the same description will apply to that well-known form, *Thompsoni*, which is so much used for bedding. The yellow-flowered *Eclipse* has its leaves spotted with golden yellow, while there is a very distinctly marked variety of the old brick-red coloured *A. Darwini*, known as *tessellatum*, in which the comparatively large leaves are marked with different shades of pale green and yellow, arranged in a peculiarly tessellated manner. This is not nearly so often seen as it was a few years ago. Of the little rambling *A. vexillarium* or *megapotamicum*, there is a variegated-leaved variety, but when growing freely it is very apt to revert to the green form. An Abutilon that requires the temperature of a stove, or at least of an intermediate house, is *A. Sellowianum marmoratum*. The leaves of this are very large and variegated in an almost indescribable manner with different shades of green and yellow. It is a very striking plant when well grown.—H. P.

#### CONTINUOUS-FLOWERING GESNERADS.

As a class, the different Gesnerads occupy a prominent position among flowering plants, for in most instances their blossoms are very beautiful, while in many the foliage is also decidedly ornamental. In several cases, too, their value as flowering plants is still further enhanced by the length of time over which the season of blooming extends, for some kinds may be had in flower throughout the greater part of the year. This latter feature is well exemplified in the numerous forms of *Streptocarpus* that are now so popular—a position they acquired by rapid bounds. Their popularity is certainly well deserved. Much the same remarks will apply to a newer introduction—*Saintpaulia ionantha*, whose pretty violet-blue flowers, lit up with yellow anthers in the centre, are borne in the greatest profusion. It is also easily grown and quickly makes headway when raised from seed, as was well shown at a recent meeting of the National Chrysanthemum Society at the Aquarium, when a small group of well-bloomed plants was shown. The plants then shown had been raised from seed sown in January. When numbers of this *Saintpaulia* are raised from seed there is a certain amount of difference to be detected among some of them in the colour of the leaves, as well as the blossoms. Up to the present there have been no very marked floral differences, but as there is a tendency to vary when raised from seed, it is probable there will be some more distinct forms before long. Should any individual show such a wide divergence from the normal form that it is desired to increase this particular plant, it can be readily done by means of leaves, exactly as in the case of *Gloxinias*, except that with these last, tubers are produced while the *Saintpaulia* only pushes out a mass of fibres, but a rosette of leaves quickly makes its appearance. In proof of this I may mention that I have some neat little flowering plants, the product of leaves put in early in the spring. The leaves were cut from the parent plant, leaving as much stalk as possible, and they were then dibbled into cutting pans of sandy soil at such a depth that the base of the blade of the leaf was level with the soil, the whole of the stem being thus buried. They quickly rooted and formed young plants that were at once potted off and shifted on as required. The resemblance between this *Saintpaulia* and the hardy *Ramondia pyrenaica* is very noticeable, and perhaps in time we may obtain a white *Saintpaulia*, as in the case of the *Ramondia*. Seed of this should be sown early in the year, and the treatment usually given to *Gloxinias* will suit it well. The *Gloxinias* are not so continuous blooming as some other Gesnerads, that is to say, they generally yield a great wealth of bloom and then quickly decline, but

still if grown in a successional manner their flowers may be had for a lengthened period. Very pretty and quaintly marked blossoms are borne by some of the *Tydaes*, and in many cases the stems will lengthen and flower continuously. I have seen the same individuals in good condition from midsummer till winter put in an appearance. The genus *Tydaea* is now-a-days not recognised by some of our authorities, one of the names substituted for it being that of *Isoloma*, and with regard to this a plant that has always borne this last mentioned generic name—*Isoloma hirsuta*, will bloom continuously. It is a good deal like the varieties of *Tydaea*, except that the mouth of the flower is rather more contracted than in the case of many of them. The colour of the flower is bright vermilion, while a singular feature is furnished by the entire plant—flowers, leaves, and stems being thickly clothed with brownish hairs. *Cyrtodeira fulgida*, also known as *Episcia fulgida*, a creeping growing stove plant, will often produce its rich glowing scarlet blossoms for six months of the year. T.

#### BEGONIA DISEASE.

I HAD hoped to see in THE GARDEN an answer to Mr. J. C. Tallack and Mr. E. Burrell giving a remedy for the Begonia disease. My plants had the disease slightly in 1892 and very badly in 1893. In April, 1894, I had about one thousand seedlings pricked out into pans and placed on a shelf near the glass in a Cucumber house. The disease began to eat them away in patches, and in some of the pans I lost them all. The leaves on some pot plants in the same house began to curl and to get into a state of stagnation in the same way as mentioned by Mr. Tallack. They were put into a warm house to push on the growth, and I came to the conclusion that it was the heat and steam from the hot-water pipes that started the disease. I could not water them without the water running down on the pipes. I then put them into cooler quarters, but I did not get rid of the disease all the year. I dipped some of the plants into a mixture of petroleum, soft soap and sulphur, which certainly seemed to check the disease. This year I started them on quite a different plan. Early in April the tubers for bedding were planted thickly in a warm south border; they did not come up very regularly, but all the best plants were taken up and planted in the beds the first week in June. They did very well indeed, and no disease. Those for pots I placed in a cold frame, and as soon as they were nice plants I put them into a cool, well-shaded greenhouse. They did not grow so large as in other years, but there has been no disease amongst them. Next year I intend to put the tubers in boxes without soil, and place in a warm house just to give them a start, and then plant out and pot them in the same way as this year.—G. C.

\*\*\* With regard to growing the tubers for summer bedding we have found that by far the best way is to start them in a cold frame on which has been placed a layer of cocoa-nut fibre, covering the tubers right over with the same material. If this is done at the latter end of March or the beginning of April the tubers will have started strongly into growth, and with a wig of roots may be transplanted to their permanent quarters in the flower garden about the end of May or beginning of June. Treated thus and kept well watered both at the roots and overhead during the summer, the soil in which they are grown being light and porous, we have found no difficulty with them.—Ed.

—The so-called Begonia disease is, I fear, rapidly increasing. It not only attacks Begonias, but *Gloxinias*, *Fuchsias*, *Achimenes*, and many things besides. Some of my *Chrysanthemums* have this summer been troubled with the same disease. Others as well as myself are under the impression that it is an insect almost invisible to the naked eye. Whatever it may be, it is very troublesome. I find flowers of sulphur very beneficial. Plants that have looked stunted and rusty

have, after an application of the above, greatly improved, making a new growth in a short time.—R. N.

\*.\* The disease attacking your plants certainly points, as we have said before, to its being thrips.—Ed.

— I think the editorial note on page 264 which assigns the supposed Begonia disease to the attacks of thrips is correct, for I have seen considerable damage caused in this way, more frequently among the fine-foliaged Begonias than among the tuberous section, though these latter are by no means proof against the attacks of such pests. It is not the large black thrips which can be plainly seen that are the cause of this damage, but very small insects of a yellowish colour, which are so minute, that a considerable amount of damage may be done before their presence is suspected. They first of all attack the younger leaves, causing them to become swollen and diseased looking, when after a time they drop. Once a plant gets into this state it is very difficult to start it into healthy growth again. The flowering class of fibrous-rooted Begonias is also particularly liable to be attacked by these thrips if the atmosphere be rather too dry and warm. Begonias are by no means the only class of plants with which these pests play havoc, many others suffering more or less from their attacks. Thus, the showy flowered *Impatiens Hawkeri* has in some places been discarded owing to the fact that it is almost impossible to get a good specimen, and so minute are the insects, added to which the mischief is usually done while the leaves are so young, that the true cause is seldom suspected. The remedy is to maintain where possible a moister atmosphere, and fumigation or some other method of destroying insect pests must also be resorted to. If the plants are dipped occasionally in any of the numerous insecticides (a strong solution of soft soap is as good as anything), they will be kept clear, but the best method of destruction is nicotine in the form of vapour. Gloxinias in a rather warm, dry atmosphere are liable to be attacked in the same way.—H. P.

— Mr. Tallack (p. 247) and Mr. Burrell (p. 275) spoke of this, and both seem to be at a loss to know how to deal with the plants affected. It is no disease at all, the black marks which begin on the stems of the plants and gradually increase till they reach the points of the shoots being caused by thrips. It is easy to find them with a small magnifying glass. The plants must be kept in a moist atmosphere during the early part of the season, lightly syringing once a day in bright weather being very beneficial. This should be continued till the flowers are opening. If the plants are kept free of the thrips till then, I do not think they will be attacked afterwards.—C. F. LANGDON.

**Hybrid Streptocarpi.**—Messrs. Veitch, of Chelsea, have now (as noted in a recent issue) a most interesting collection of these useful plants. When I visited the nursery a week or two back—rather late in the season to see these plants at their best—I found that a great advance in the matter of colour had been made. Self-coloured flowers in pink, rose, red and purple of varying shades were there in plenty, together with delicately-marked flowers, in which one or other of these colours was to be found on a white ground. Pure white forms were there, too, but not so plentiful as the coloured forms. A good strain of unstained white flowers will be useful for special purposes, but for me they have not the charm which coloured flowers have, as even the faintest of lines along the tube seems to enhance and accentuate the beauty of form which the flowers possess. As the plants set apart for seed-bearing were arranged in blocks of one colour or shade, it is possible that we may be able in future to get seeds of each colour separately, and this will be a considerable help to the grower.—J. C. TALLACK.

**Asparagus Sprengeri.**—I consider this one of the most distinct of all the indoor species, and

as a contrast in form, habit and colour to *A. plumosus*, *A. decumbens*, &c., it well merits the attention of all interested in greenery for bouquets, wreaths and sprays. But it is most handsome as seen drooping gracefully and naturally from pot or hanging basket in a warm plant house or conservatory. I originally obtained the plant some years ago from Messrs. Dammann and Co., of Naples, and it has been much admired by visitors, none of whom ever saw it before. It is an evergreen species with silvery tubers, reminding one of those of some kinds of *Oxalis*, and its growths are thrown up in a free and plumose manner "like Prince of Wales feathers," as a lady said the other day. These feathery growths vary from 2 feet to 8 feet or 10 feet in length, and, being

into Covent Garden Market by the hundred, seeing that it grows so freely and endures fresh and fair all the year round. In Italy it can be grown in the open ground all the warmer part of the year, and as it is offered cheaply and in quantity, it should, as it deserves, soon become known to our market growers of select decorative materials.—F. W. BURBIDGE.

**Burbidgea nitida.**—Many of the Gingerworts are noteworthy by reason of their attractive blossoms, and this is one of them, for the flowers are not only showy, but, being borne at this season of the year, are doubly welcome. It is a far less vigorous-growing subject than the *Alpinias*, *Hedychiums*, and some other allies, for the *Burbidgea*, as a rule, only reaches a height of

*Astilbe japonica.* (See p. 355.)

of a fresh light or Apple green hue, are admirably adapted for all delicate decorations indoors. I have had cut fronds in water that were quite fresh six weeks after they were cut from the plants. Like all the species, this will grow in almost any soil, but in large pots or baskets of rich compost with a handful of bone-dust the plumes are very long and beautiful. Another way is to plant out the crowns along the margins of the stages and allow the growths to fall over naturally like a green curtain or a cascade. My plants are in pots on a shelf and hang down over the head of a doorway, and they form an admirably fresh green background for a few *Cattleyas* or *Dendrobies* in flower. The wonder is that such a distinct plant has not long ago found its way

about 18 inches. The stems are slender, clothed with bright green glossy leaves, while the flowers, which are borne in a terminal panicle, have some of their parts considerably reduced, the principal ornamental portion consisting of three segments which are of a bright orange colour that deepens with age, the exterior of the bloom, too, being always darker than the inside. The roots do not penetrate to any great depth, hence in cultivating it in this country pans are to be preferred to pots. Good drainage, too, is essential. This *Burbidgea* is a native of shady forests in North-West Borneo at an altitude of 1000 feet to 1500 feet, in spots where there is little undergrowth. In a wild state it thrives best where the rhizomes form matted masses on moist rocks

covered with vegetable debris, and it then frequently produces from ten to thirty slender flowering stems, each bearing a panicle of twelve to twenty flowers. This plant is named after Mr. Burbidge, who discovered it in 1878 when travelling for Messrs. Veitch. In addition to its other features, Mr. Burbidge remarks the pleasing fragrance emitted by the rhizomes when they are disturbed in any way.—H. P.

## SOCIETIES AND EXHIBITIONS.

### CRYSTAL PALACE CHRYSANTHEMUM SHOW.

NOVEMBER 2.

THIS show, held on Saturday last, was well attended, and brisk competition was manifest in all classes. Every type of the flower was admirably represented in the cut flower sections of the show, but the growth of specimen plants seems to have lost its charm even with the limited few who used to exhibit them. There was only one really creditable lot of trained plants in the show; these were standards, but an excellent lot, abundantly flowered, and not at all stiff.

The chief class here is that for thirty-six Japanese blooms in not less than twenty-four varieties. We doubt if a finer stand will appear at any London show than that which won the first prize. It was shown by Mr. W. H. Lees, gardener to Mr. F. A. Bevan, Trent Park, Barnet. The flowers throughout were even in size, and fresh. The best blooms were those of Mrs. W. H. Lees white; Phœbus, yellow; Mme. Carnot, white; Mutual Friend, white; G. W. Childs, deep crimson; H. L. Sunderbruch, yellow; Mme. G. Biron, chestnut-red; Mme. A. Moulin, white; Sunflower, yellow; Chas. Davis, buff; Mlle. Thérèse Rey, cream-white; Reine d'Angleterre, rose; Miss Dorothy Shea, bright chestnut-red; Mons. C. Molin, bronze-yellow, deeply coloured; M. Pankoucke, yellow; and International, a large flower, but flushed with lilac, and by no means so beautiful as the great flourish that was made on its first appearance would lead one to suppose. The second place fell to Mr. J. W. McHattie, gardener to the Duke of Wellington, Strathfieldsaye, who had many good blooms. He was ran closely by Mr. C. J. Salter, gardener to Mr. T. B. Haywood, Reigate. For eighteen distinct Japanese there were nineteen entries, and few points divided the winning stands. The first prize fell to Mr. C. Cox, gardener to Mr. J. Trotter, Brickenden Grange, Hertford. The best blooms were Eda Prass, W. Seward, Mrs. Falconer Jameson, Viscountess Hambledon, T. Wilkins, Col. W. B. Smith, Commandant Blusset, M. Pankoucke and E. Molyneux. Mr. W. Collins, gardener to Mr. J. W. Carlisle, Ponsbourne Park, Hertford, was a very good second. The third lot in such a well-filled class would naturally be good, and Mr. A. Jones (gardener to Miss Wyburn, Hadley Manor, Barnet) filled that position with a very good stand of flowers. The best twelve Japanese were shown by Mr. G. Smith, gardener to Mr. R. W. Inglis, Craigen-dowie, Reigate Hill, Mr. H. Butcher being second. There were eleven entries in this class, with close competition throughout. For six Japanese one variety, out of sixteen exhibits, Mr. W. Robinson (gardener to Lord Justice Lopes, Westbury, Wilts) was first with very fine deeply-coloured flowers of Vivand Morel. Mr. Charles Cox was second with Col. W. B. Smith; these also a handsome and much-admired lot. The reflexed and Japanese reflexed class seems to have led to some confusion, as all the exhibitors were disqualified; but three extra prizes were awarded to Mr. W. Robinson, Mr. R. C. Noteutt, Ipswich, and Mr. C. J. Salter.

The best twenty-four incurved blooms were also shown by Mr. W. H. Lees, and here again evenness and perfect finish characterised every flower in the stand, Empress of India, white; Globe d'Or, buff-yellow; Jeanned'Arc, white, flushed with lilac; Lord Alcester, cream; Baron Hirsch, deep

buff; Charles H. Curtis, rich yellow, two fine well finished blooms being shown; Miss Haggas, pale yellow; Golden Empress and Violet Tomlin being all first-rate flowers. The second lot came from Mr. J. Dumble, gardener to Sir Charles Phillips, Picton Castle, Havcrfordwest, but there was a marked falling off in depth and finish as compared with the first stand. For eighteen incurved distinct varieties the first prize went to Mr. T. Robinson, gardener to Mr. W. Lawrence, Elsfeld House, Hollingbourne, Kent. His best blooms were those of Mme. Darrier, D. B. Crane, John Lambert, Miss Haggas, Mrs. S. Coleman, Lucy Kendal and Queen of England. The second prize went to Mr. J. Wyatt, gardener to Mr. J. Perry, Bradenhurst, Caterham Valley. Mr. H. Butcher, gardener to Mr. C. Buss, Smeeth Ashford, Kent, was first for twelve incurved blooms with a good, fresh, well-finished lot, M. P. Martignac, rich yellow, being a telling flower in this exhibit. The second lot was shown by Mr. A. Sturt, gardener to Mr. W. L. Cohen, Round Oak, Englefield Green. The class for six blooms of any incurved variety brought out a strong competition, fifteen exhibits appearing. Mr. H. Butcher was awarded first with grand deeply-coloured blooms of the rich bronze variety Baron Hirsch. Mr. J. Wyatt was second with the same variety, which was shown by seven exhibitors in this class.

In the Anemone-flowered class for eighteen distinct varieties, Mr. H. Prickett, gardener to Mr. John Harvey, East Barnet, was first, showing good flowers of W. W. Astor, John Bunyan, Dame Blanche, Sir W. Raleigh, Lady Margaret, and Judge Benedict. The second prize went to Mr. J. Milner, gardener to Mrs. Higgs, Willenhall Park, Barnet. There was good competition here with nine exhibits. The best twelve Anemone-flowered Japanese came from Mr. J. Milner, the second prize falling to Mr. H. Prickett. For twelve singles, distinct varieties, three blooms of each, Mr. W. Wells, Redhill, was first, and Mr. W. C. Pagram, gardener to Mr. J. Courtenay, Weybridge, second. As regards the pompons, there is a growing tendency to force these to an inordinate size, and the judges wisely passed over one lot of great blooms not at all like what pompons should be, giving the first award to Mr. C. J. Salter, who showed a pretty lot of bright fresh flowers. Mr. H. Harris, gardener to Mrs. Eversfield, Denne Park, Horsham, was second. Messrs. Salter and Harris were similarly placed in the class for twelve Anemone pompons.

The best group arranged in a space of not less than 100 square feet, and of Japanese varieties only, was shown by Mr. W. Wells, who departed somewhat from the conventional style of arrangement, with an improved result. Mr. W. E. Tidy, Brockhampton, Havant, was second, with well-flowered, but stiffly-arranged plants. A class for a group occupying half the above-mentioned space, open to amateurs only, was not well filled, Mr. W. Webster, gardener to Mr. W. Higgs, Binfield Road, Clapham, receiving first with the only group shown. For the best group of Japanese kinds arranged for effect with Crotons or any other fine-foliaged plants, Mr. W. Howe, Park House, Streatham, was first, with a pretty arrangement, that might have been made even more effective but for the rather absurd limitation to an oval space only 14 feet long and 10 feet broad. The second prize went to Mr. T. Wilks, gardener to Mr. M. C. Ralph, Cranbrook Villa, Upper Norwood. Mr. G. H. Cooper, Sydenham Road, Croydon, showed a good lot of standard-trained plants. The single specimen plants, too, were good, Mr. W. Leakey (gardener to Mr. J. M. Douglas, College Road, Upper Norwood) being first, and Mr. G. H. Cooper second, both showing freely-flowered plants of the variety W. H. Lincoln. For an arrangement of cut Chrysanthemums with Crotons, Ferns or autumn-tinted leaves, Mr. W. D. Aspland, florist, Crystal Palace, was first with a large and graceful exhibit.

The miscellaneous exhibits were not numerous on this occasion, but comprised a group of Chrysanthemums from Mr. T. S. Ware, Tottenham; a graceful arrangement of Chrysanthemums and

other flowers in bouquets, wreaths, baskets and other designs from Miss M. Jackson, Upper Norwood; and pompon and single Chrysanthemums from Mr. W. Wells. Mr. Briscoe-Ironside showed some of his new varieties and his revolving flower-stands, designed to supersede the show-board. Messrs. J. Laing and Sons arranged a pretty group of fine-foliaged plants and Vine leaves. Grapes and Tomatoes were shown by Messrs. W. and D. Buchanan, Forth Vineyard, Stirling.

A full prize-list is given in our advertisement columns.

### NATIONAL CHRYSANTHEMUM SOCIETY.

NOVEMBER 5, 6, 7.

THE chief show of the present season held under the auspices of this society opened at the Royal Aquarium, Westminster, on Tuesday, and it was generally acknowledged to be one of the finest shows that has ever been held, not only in the matter of competition, but also in the high quality of the flowers that was manifest throughout. The Japanese type of flower was paramount throughout the show, and the most recent additions to this class were generally shown to such an extent, that varieties which occupied leading places less than a decade ago are now scarcely seen. Whilst we cannot speak of the exhibition but in terms of the highest praise, we cannot help thinking that the arrangements might be greatly simplified and improved. In several cases it was only by chance that we found the winning stands in some of the smaller classes. If the numbering of the schedule cannot be consecutively followed throughout, surely it is possible to put the leading classes in something like sequence, instead of which we had to make a complete tour of the place. To cite an instance, we may mention class 12, in which there were only four entries, yet we found the first prize and another exhibit in one spot, and the second and third lots about 20 yards away. Such a system, or lack of system, tends to friction and unpleasantness that might be wholly avoided.

### CUT BLOOMS.

These are always the chief feature of this exhibition, though never before has one exhibitor met with such extraordinary, but none the less well-deserved, success as Mr. W. H. Lees, gardener to Mr. F. A. Bevan, Trent Park, Barnet, who won the challenge trophy and both of the Holmes Memorial challenge cups. In the national competition of Chrysanthemum and Horticultural Societies, of which any number of members is allowed to contribute blooms, Mr. W. H. Lees, showing as a member of the Southgate and District Society, won the prize entirely with his own flowers, and a finer forty-eight were never seen. The Japanese kinds were Mme. Carnot, Charles Davis, Sunflower, Eva Knowles, Louise, Van den Hede, Mutual Friend, Mons. G. Biron, M. Pankoucke, Col. Smith, Mrs. Harman-Payne, Mme. Moulin, E. Molyneux, Phœbus, Mons. C. Molin, T. Wilkins, Vivand Morel, Mlle. A. de Galbert, Miss Dorothy Shea, H. L. Sunderbruch, Miss Rita Schreter, Mrs. W. H. Lees, Charles Shrimpton and Mlle. Thérèse Rey. The incurved kinds were Empress of India, Minnie Davies, Lady Harding, Prince Alfred, Golden Empress, Hero of Stoke Newington, Lord Alcester, Louisa Kendal, Mrs. Shipman, Mons. Bahuant, C. H. Curtis, Mme. Mistral, J. Agate, Baron Hirsch, Mrs. Heal, Globe d'Or, Queen of England, Violet Tomlin, Robert Petfield, Mrs. Coleman, Brookleigh Gem, John Lambert, Lord Wolseley and Jeanne d'Arc. We have given the list of names, as doubtless it will be of general interest, and it is needless to individualise where all were so perfect. The second prize went to the Bromley and District Society, and in contrast to the success of the previous exhibitor, the flowers in this lot were contributed by nine growers. The Brighton and Sussex Society was placed third. There were five lots shown in this class. For forty-eight Japanese blooms, distinct—the first prize, one of the Holmes Memorial cups and £10—Mr. Lees

was again an easy first, with a superb lot of flowers. Mr. W. Mease, gardener to Mr. A. Tate, Downside, Leatherhead, was second, and Mr. W. Wells, Redhill, third. The eight lots in this class made a brave display. Another Holmes Memorial cup and £10 are given for the best thirty-six incurved blooms, and here again Mr. W. H. Lees was invincible, being an easy first. In a stand of great evenness throughout, special mention must be made of J. Agate, Globe d'Or, R. Petfield, Mrs. Coleman, C. H. Curtis, Mme. Darrier, C. Gibson, M. P. Martignae, Louisa Kendal and Jeanne d'Arc. Mr. W. Mease was second with a very nice lot. For some non-apparent reason the next class for twenty-four incurved was placed upstairs opposite classes 25 and 6. The first place was given to Mr. B. Calvert, gardener to Col. Archer Houbton, Hollingbourne Place, Bishop's Stortford, his best flowers being those of A. Salter, Lord Wolsley, Refulgence, Violet Tomlin, Miss Haggas and Lord Rosebery; Mr. J. Robinson, gardener to Mr. W. Lawrence, Elstead House, Hollingbourne, being second. The best twelve incurved blooms were shown by Mr. Walker, Goldbeaters, Mill Hill; Mr. R. Ridge, gardener to Mr. C. Swinfin-Eady, Outlands Lodge, Weybridge, being second. Of six incurved blooms, one variety, ten lots were shown, half of them again being Baron Hirsch, but Mr. J. H. Walker won with six perfectly finished flowers of Jeanno d'Arc. Mr. B. Calvert was second with fine flowers of Alfred Salter.

Mr. H. J. Jones, of Lewisham, offered a cup of the value of five guineas in addition to the society's first prize for twenty-four Japanese blooms, distinct. This class brought out twenty competitors, and the whole lot was a show in itself. Mr. W. Messenger, gardener to Mr. C. H. Berners, Woolverstone Park, Ipswich, was first, showing grand flowers of Mrs. C. Harman-Payne, Col. Smith, W. Marshall, Violet Rose, Waban, Lord Broeke, and Mrs. G. J. Beer in his stand. The second prize went to Mr. G. W. Drake, Cathays Terrace, Cardiff, and the third to Mr. W. Allan, Gunton Park, Norwich. Mr. Jones offered a similar cup for twelve Japanese blooms, distinct, and there was about the same number of competitors in this class, Mr. J. Agate, Havant, winning first prize with a fine stand.

For the best six Japanese blooms of one white variety, Mr. R. Jones, gardener to Mr. C. A. Ryland, Barford Hill, Warwick, was first with superb flowers of Mlle. Thérèse Rey, Mr. J. Sandford second with Mlle. Marie Hoste. In a similar class for any colour except white, Mr. R. C. Notcutt, Ipswich, was first with blooms of Edith Tabor, a lovely flower with broad curled florets and of a soft clear yellow colour. Mr. B. Calvert was second with Col. Smith. For six incurved Japanese, distinct, we found that among four lots Mr. J. Agate, Havant, was awarded a third prize, and as these were excellent flowers, doubtless there were other exhibits in the class not discernible in the confused state that prevailed. An interesting class was that for six distinct Japanese varieties, exhibition blooms, three of each, one variety only in each vase and showing at least a foot of stem above the vase. Mr. D. M. Hayler, gardener to Mr. W. Hannaford, Tentorden Hall, Hendon, was first with very fine flowers, Duke of York particularly striking. Mr. C. H. Martin, gardener to Mr. R. H. Langton, Hendon, was second. For six blooms of hairy-petalled varieties, Mr. Wells was first, showing L. Bohmer, White Plume, Hairy Wonder, Miss Higginbotham, Mrs. W. J. Godfrey, and another. Mr. H. Love, Melville Terrace, Isle of Wight, was second. Mr. R. C. Notcutt showed admirably in the class for twelve large-flowered reflexed blooms, those of Christine, Cloth of Gold, Golden Christine, King of Crimson, and Cullingfordi being the finest in a nice fresh lot. Mr. J. H. Walker was second.

The best twenty-four Anemone-flowered kinds came from Mr. W. Skoggs, gardener to Mr. A. Moseley, West Lodge, Barnet. These were a charming lot, the best being Gladys Spaulding, Cincinnati, John Bunyan, Nelson, W. W. Astor,

M. Dupanloup, Descartes, Fleur de Marie, Queen Elizabeth, and Enterprise. The second prize went to Mr. A. Ives, gardener to Mr. E. C. Jukes, Hadlow Lodge, High Barnet. There were seven good lots in this class. In the two following classes for flowers of the same type, Mr. Skoggs was first. For twelve Anemone pompons, three blooms of each, Mr. C. Brown, gardener to Mr. R. Henty, Langley House, Abbots Langley, was first with a charming lot, especially the trebles of Francis Bryce, Mme. Monties, and Miss Nightingale. Mr. J. Myers, gardener to the Earl of Sandwich, Hinchinbrooke, Huntingdon, was a good second. For twelve pompons, excluding those of Anemone form, Mr. C. Brown was first, his best trios being Prince of Orange, Elise Dordan, Miss Bateman, Black Douglas, Mmc. Martha, W. Westlake, and Charles Dickens. Mr. T. Conyer was second. The twelve sprays of single-flowered kinds that won the first prize for Mr. J. Myers were the most charming lot we have ever seen, the varieties being Jane, white; Mary Anderson, blush; Purity, blush-white; Gold Star, yellow; Nora, deep rose; Foxhunter, chestnut-brown; Snow Wreath, white; Oceana, blush-pink; Admiral Symonds, yellow; Mrs. D. B. Crane, rose-pink; Bessie Conway, white, tipped with lilac; and Miss M. Wildo, deep rosy lilac, with lighter centre. Mr. W. C. Pagram, gardener to Mr. J. Courtenay, The Whin, Weybridge, was second, with another pretty lot.

The amateurs' classes were also well filled. For twenty-four Japanese, in eighteen varieties, Mr. J. Stredwick, Silverhill, St. Leonards, was first, and Mr. C. A. Jessop, Mildenhall, Suffolk, was second. Mr. J. Stredwick also secured first prize for twelve Japanese distinct varieties, the second prize going to Mr. H. Love. For twelve incurved blooms, Mr. W. Amies, Ashford, Kent, was placed first, the second award going to Mr. G. R. Crowns, Long Ditton. The best six incurved came from Mr. C. E. Wilkins, Swanley, the second lot coming from Mr. G. D. Willis, East Finchley. There were eighteen entries of six distinct Japanese, Mr. H. Love coming out successful, with Miss A. L. Gaunt, of South Tottenham, second. For a similar number of one variety, Mr. H. Love was again first with Sunflower, and Mr. J. Stredwick second with Vivand Morel, fine and deep in colour. Several classes are set apart for single-handed gardeners, and in these Mr. S. J. Cook (gardener to Mr. J. H. Hart-ridge, Hendon) was first for twelve incurved, Mr. W. C. Pagram showing the best six in the next class. Mr. W. Perrin, gardener to Mr. W. Richardson, Sawbridgeworth, was first with a good dozen Japanese, the second place going to Mr. Pagram. Metropolitan flowers are likewise encouraged, Mr. F. Bingham, Stoke Newington, being first in this division for twelve incurved blooms, very fair flowers being shown. For six of the same form, Mr. J. Brooks, gardener to Mr. Reynolds, Highgate, was first, and Mr. Bingham second. Mr. Brooks was likewise first with twelve distinct Japanese, the second prize going to Mr. W. Davies (gardener to Mr. W. F. Darnell, Devonshire House, Streatham Hill). Mr. W. Davies also showed the best distinct half dozen, followed by Mr. J. Brooks, and for the same number of one variety, Mr. W. Farrow (gardener to Mr. G. R. Peerless, Park Hill, Streatham) was first with good flowers of Charles Davis; Mr. W. Davies came second with Col. Smith.

Mr. Jones, of Lewisham, made a bold arrangement on a table 18 feet by 6 feet of cut exhibition blooms. The flowers were shown on long stems and intermingled with Crotons and Ferns; the first prize was well awarded here. The best three vases, each to contain twelve blooms arranged with any foliage, were shown by Mr. D. M. Hayter, Mr. J. Prewett, Hammersmith, winning in the next class for three epergnes. For two vases of the smaller-flowered kinds, Mr. M. Webster, Kelsey Park, Beckenham, was first, the same exhibitor being successful with two graceful hand bouquets. The best hand-basket, open only to ladies, was shown by Mrs. Newell, Victoria Road, Wimbledon. For a single vase of six blooms of one variety arranged with any foliage, Mr. A.

Felgate, gardener to the Duchess of Wellington, Bunhill, was first, and in a similar class for amateurs, Mr. E. Jones, Malvern Road, Hornsey, was successful. The best hand-basket of autumn leaves and berries was shown by Mr. J. Mansey, Islington. The special prizes offered by Messrs. Williams, of Holloway, for six blooms of Philadelphia went to Mr. W. King, gardener to Mr. J. Colman, Gatton Park, Reigate, and Mr. W. Mease, whilst for three blooms, Mr. Norman Davis and Mr. T. Conyer were successful. In all fourteen lots of this new kind were shown.

#### PLANTS.

The usual number of classes was set apart for these, the groups being the centre of attraction. Mr. H. J. Jones had the finest group, a bold, yet graceful arrangement, in which he departed somewhat from the conventional sloping form, the finely flowered plants relieved with Bamboos, Palms, Crotons and Ferns. Mr. Norman Davis, Camberwell, was a very good second, his arrangement being a good and tasteful one. For six trained specimens and likewise for six standard-trained plants, Mr. D. Donald, gardener to Mr. J. G. Barclay, Leyton, was first with plants exceedingly formal in training, but freely flowered. The best six trained plants of pompons came from the same exhibitor, and were of the same high quality as regards quantity, perfection and freshness of bloom. Mr. Donald was the only exhibitor of a specimen plant, but this was a grand one, a huge pyramid of Margot, which must have had several hundred blooms, very uniform in size and colour and well distributed all over the plant. In two classes for four trained plants, Mr. W. Davey, gardener to Mr. C. C. Paine, Cedar House, Stamford Hill, was first with well-flowered plants.

Miscellaneous exhibits were also extensive and varied. Mr. T. S. Ware, of Tottenham, put up a large group of some of the finest Japanese kinds, and from the Jadoo Fibre Company came a good group, which showed conclusively that these flowers can be grown to perfection in this material. They were in 8-inch pots and carried fine flowers, notably the following varieties: Col. Smith, Mme. Carnet, Sunflower, G. S. Shrimpton, Vivand Morel and Charles Davis. From Messrs. J. Veitch and Sons, Chelsea, came a fine group of Chrysanthemums well arranged with Bamboos in relief. Mr. E. Tidy, Brockampton Nurseries, Havant, made a large display with cut Chrysanthemums arranged with Palms and Ferns in a free and pleasing way, Japanese, pompon and single varieties being prominent in many-flowered sprays. Messrs. H. Cannell and Sons, Swanley, showed cut Chrysanthemums in great numbers, their collection of Japanese varieties very comprehensive, Pride of Madford, Mons. Leon Dabat, James Myers, Australia, a new and large Japanese incurved of the E. Molyneux type, E. T. Ewing, A. H. Wood, G. W. Childs, A. Lancaster, and Philadelphia being noteworthy. Mr. Norman Davis showed a few fine flowers of new Japanese kinds arranged above a groundwork of Ferns. Messrs. Williams, of Holloway, put up one of their characteristic groups, in which, besides tasteful arrangement, Cattleya labiata in variety, Heaths, Crotons, Solanums, Chrysanthemum Philadelphia, and Cyclamens were prominent features. Messrs. Cutbush showed a bright group of Palms, Grasses, winter-flowering plants, Cyrtopodiums, Oncidium, Odontoglossums, Heaths, Cyclamens, and Chrysanthemums. Mr. H. Shoosmith, Claremont Nursery, Woking, showed fine new Japanese kinds, notably Pallanza, rich yellow; W. Seward, Col. W. B. Smith, richly coloured; M. Gruyer, M. Charles Molin, Duchess of York, lovely flowers, full and graceful; Rose Wynne, very distinct; M. Pankoucke, grand blooms; W. Bolia, rich amaranth-red, silvery reverse, and very pretty; Deuil de Jules Ferry, deep crimson-amaranth, rosy reverse, and a grand new kind. Mr. W. J. Godfrey, Exmouth, exhibited Japanese varieties in quantity, the best being Mrs. J. B. Brice, a reflexed Japanese of graceful form and rich clear pink colour, a variety certain to become popular; Mrs. Hume Long,

long drooping florets, large, but not coarse, deep rose with silvery reverse; Miss Louise D. Black, very rich in colour; Mutual Friend, white; Reine d'Angleterre, Douil de Jules Ferry, President Carnot, white intermingled florets, extra good; Mrs. W. J. Godfrey, incurved white; Clinton Chalfont, reflexed, rich yellow, likely to be one of the most popular decorative varieties. Mr. R. Owen, Maidenhead, showed two fine stands of new varieties, which included good blooms of Dorothy Gibson, yellow reflexed; R. Petfield and G. Haigh, incurved, the latter a distinct sport from the former. Good Japanese flowers were J. Bidencope, Pride of Maidenhead, cream-white, with yellow centre, a graceful flower; Eva Knowles, rich buff; Lady Ridgway, and several very fine unnamed seedlings.

#### FRUIT AND VEGETABLES.
